may be more satisfactory. French Beans and Scarlet Runners are very late; we have not yet, August 20th, gathered any outside. Potatoes are a fine crop, and I am happy to say I have not yet discovered any disease. Turnips, Carrots, Parsnips, Beet, and Shallots are very good; spring Onions are in some cases affected with maggot. Cabbage, Cauliflowers, and Lettuce have been very good. I find Veitch's Earliest of All Cabbage an excellent variety of good size and shape, and rich flavour. The same remark applies to Veitch's Early Forcing Cauliflower, which is a most useful kind for early cultivation, and their Perfect Gem Cabbage Lettuce is a gem indeed. Vegetable Marrows are late in coming in; we have, however, been cutting a few during the past fortnight.

Herbaceous plants have flowered profusely, and are making a grand show, and it is long since I remember to have seen such a wealth of blossom on all kinds of hardy trees and shrubs. There is an abundant crop of berries on the Holly this season. Should fine weather now happily continue I think we shall have cause to be thankful; the abundant supply of rain has indeed been a great boon to many farmers and gardeners on the steep limestone hills of North Derbyshire.—WALTER G. GAIGER, *The Gardens, Burton Close, Bakewell.*

DEVONSHIRE.

THE weather here has been very unsettled, especially during July, with a considerable rainfall, and frequently accompanied with dense fogs from the sea, doing damage to tender foliage. The Purple Beech, Golden Oaks, and some of the Conifers have the appearance of having been burnt. H.P. Roses have lost their foliage completely; of German and Ten-week Stocks the flowers have decayed; on the other hand I never saw the mixed borders more gay in August. Herbaceous Phloxes, Zinnias, Clarkias, Carnations, Dahlias, both single and double, are all that one can desire. The Gladiolus are healthy and strong, just showing their flowers. All vegetables have grown unusually strong. The late-sown Peas have suffered from mildew to such an extent that they will be worthless. The Tripoli Onions grew to a larger size than I ever saw in any previous year. The spring-sown Onions will be thick in the neck, consequently the bulbs will be inferior. Potatoes are now badly diseased; the crops are very heavy; the fine drying winds we are having may do something to arrest the disease.

On reference to my weather table I find the following results:—June, seventeen dry days, and more or less rain fell on the remaining thirteen days, 3.16. July, seven dry days, and rain fell on twenty-four days to 5.28. The temperature was unusually low. On June 14th the lowest temperature was 34°, the highest was on June 23rd, 77°. On July 8th the temperature was 72°. The coldest night was the 17th, 39°. The rain gauge used is 5 inches in diameter.—GEO. BAKER, *Mumbland Gardens, Plympton, S. Devon.*

DUMFRIESSHIRE.

THE weather here during the month of June was very unseasonable. The sun being strong during the day with cold north-east winds, often a low temperature at night. On the 5th of June we had 7° of frost, and on the 30th 2° of frost. Mean temperature for the month 52.36°, hours of sunshine 186, rainfall 1.97 inch. The corresponding month last year, mean temperature 57.9°, hours of sunshine 238, rainfall 0.68 inch.

July of this year all through was dull and showery, only nine days without rain. We had 3° of frost on the 1st, 3° on the 8th, 2° on the 11th, and down to freezing point on the 31st; rainfall 4.54 inches; mean temperature 53.42°; hours of sunshine 81. The corresponding month last year: rainfall 5.34 inches; mean temperature 59.2°; hours of sunshine 155.

Garden crops and outdoor flowering plants made little progress during June, especially the bedding plants. After the first week of July vegetables made rapid progress. Most notable amongst vegetables were Peas, Cauliflower, Brussels Sprouts, Cabbage, Borecole, Onions, Potatoes, Turnips, and Celery.

The bedding plants that have done best are Calceolarias, Begonias, and Lobelias. Pelargoniums, although growing pretty well of late, are deficient in bloom. Sweet Peas, Ten-week Stocks, Chrysanthemum segetum, and Chrysanthemum Dunnetti. White Candytuft, Saponaria calabrica, and Tagetes are flowering well. Asters, Senecio elegans, and Antirrhinums are promising well, but not in flower. Dahlias, both double and single, are only coming into flower. Herbaceous Pyrethrums, Pinks, Delphiniums, Spanish and English Irises, Spiraeas, and Roses have done remarkably well.

Regarding the fruit crops, Pears are a failure this season, with the exception of Beurré Diel, Jargonelle, Beurré de Capiaumont, and Williams' Bon Chrétien, which are carrying a moderate crop. Apples are much under average, and the only trees that are carrying moderate crops are Ecklinville, Keswick Collin, Cellini, Stirling Castle, Lord Suffield, Northern Greening, Pott's Seedling, and Betty Geeson. Plums are a failure, with the exception of Victoria (which is bearing a heavy crop), Magnum Bonum, and Reine Claude de Bayay. Cherries no fruit on early trees. Morellos are a fair crop. Small fruits, with the exception of Strawberries, are above an average.—JAMES DICKSON, *Castlemilk Gardens, Lockerbie.*

EAST LOTHIAN.

JUNE was ushered in with a frost, which did much amount of damage, some localities suffering to a greater extent than others, but few, if any, escaped. The earlier Strawberries were rendered almost worthless, and many Potatoes damaged. French Beans also suffered, and bedding plants in some places to a serious extent. The weather throughout June was cold, east winds prevailing. July was comparatively

colder still, a greater amount of rain falling in the latter month, and the temperature on several occasions being below 40°. The June rainfall was 2·37 inches; average, 2 inches. July, 4·47 inches; average, 3 inches.

Of garden crops Potatoes are about half the weight of a good season, but the quality is good, and there is no disease; Peas are thinly podded, and do not fill; French Beans are not yet ready; Lettuces and that class of plants very fine; Carrots fine; Turnips small; of fruit Strawberries over the whole about half a crop, quality deficient; Apples a good crop; Pears fair; Apricots and Peaches a large crop, also Cherries; Plums poor; small fruits generally below the average. All, of course, are late.

Bedding plants have been extremely backward. Tender plants such as Iresines, are quite failures; Violas have done badly, Lobelias and Calceolarias doing best; Dahlias are very small and late; Pelargoniums the same; Pentstemons are very fine, also Pinks and Carnations; border Chrysanthemums healthy, though late; Delphiniums, Roses, Phloxes, Hollyhocks, and most herbaceous plants are growing well, and are firm; Gladioli were damaged with frost, but are now looking better, we are now cutting from these; Lemoine's hybrids rather earlier than the others.

With fine weather now and later on the season may in some respects prove not so bad in the end, but with the same weather we have had matters will be very bad all round.—R. P. BROTHERSTON, *Tynninghame Gardens, Prestonkirk*.

GLAMORGANSHIRE.

THE rainfall here in June was 3·48 inches, which fell on sixteen days. The maximum temperature in the shade ranged from 60° to 76°, and the minimum from 41° to 54°. The prevailing winds during the month were from the east and west. There was a severe thunderstorm on the evening of the 25th, accompanied with heavy showers of rain and hailstones, which did some injury to fruit trees and vegetable crops. The rainfall in June, 1887, was 0·61 inch. The rainfall in July was 7·35 inches, which fell on twenty-seven days. The greatest fall was on the 7th, when we had a severe thunderstorm. The maximum temperature during the month ranged from 59° to 67°, and the minimum from 42° to 57°. The prevailing winds were from the south-west and north-west. The rainfall in July last year was 1·51 inch.

Of Apples and Pears there are very good crops, both on pyramid and wall trees. Plums are very scarce here, but good crops in some gardens in the district. Peaches a poor crop, and the trees much blighted in some places. Strawberries were a partial failure on account of so much rain during the time they were ripening. Gooseberries and Red, White, and Black Currants plentiful and good where the buds were not destroyed by sparrows. There are good crops of most vegetables, but some of them have been a little later than usual. The early Potatoes are very badly diseased in this locality, and there is not more than half a crop. Late Potatoes are much better.

Both annuals, perennials, and bedding plants have done well here; and Roses have been very fine this season, and the blooms bright in colour.

The Vines at Castle Coch are a complete failure this year on account of so much rain and want of sunshine during July, and they never promised better for a good crop than they did in June.—A. PETTIGREW, *Castle Gardens, Cardiff*.

GLOUCESTERSHIRE.

THE cold wet time we have passed through has had a most retarding influence on vegetation generally, and nowhere are its effects more noticeable than in the kitchen garden, where the crops are later than they have been for years. Peas and Broad Beans have filled slowly, but the quality has been good, although in some instances the growth has been very rampant. Kidney Beans have grown strongly, the crop being excellent, but we were unable to gather any until this month, and the Runners follow slowly. Amongst Vegetable Marrows, Moore's Cream has proved the best this season, fruiting more freely than any other variety we grow. Potatoes are a good crop of fair quality, but the disease is showing itself rather freely. Onions are strong, but bulbing slowly, and unless the autumn happens to be very favourable they stand a poor chance of keeping well throughout the winter. Broccoli and other winter vegetables are growing luxuriantly. Small fruits are plentiful, but the wet proved most destructive to Strawberries, causing a deficiency in flavour, and many to decay on the ground. A notable exception was Loxford Hall Seedling, which for the first time has been satisfactory.

Roses never looked more promising than early in the summer, but as the garden has rather a low situation the weather was too much for them, and many buds of the more tender varieties decayed without opening. The more hardy sorts did very well, being especially fine in colour. In the flower garden no other plants have flowered so freely as the Tuberous Begonias. Pelargoniums have been better than might be expected, although somewhat inclined to rankness of growth. Verbenas, Petunias, and Calceolarias made good growth during the wet weather, and are now a mass of bloom. Carnations have been late, and not so good as they usually are. Mesembryanthemums and other tender bedders have done fairly well, with the exception of Alternantheras. Iresine Herbsti has been very effective. Herbaceous plants generally have grown well, and make promise of a good autumn bloom. Ferns have had a glorious time of it, and their appearance shows how well they can appreciate such weather.—J. MACDONALD, *Angeston*.

HERTFORDSHIRE.

MOST of the kitchen garden crops have suffered more or less here owing to the continuous rain and absence of sun. In June we had sixteen rainy days, the rainfall was 3·79 inches. In July we had twenty-six rainy days, rainfall 4·13 inches. Our gardens are late as a rule, the soil being very heavy, with a subsoil of strong clay. Potatoes in this district are a good crop, but the disease is very prevalent. Snowdrop is our favourite variety, the tubers of which are clean and good. Peas made an abundance of growth, but were late coming in, and filled badly; the best were Prodigy and Duke of Albany. Carrots, Parsnips, and Beet good. Onions eaten very much by the maggot.

With scarcely a fine day in July the summer bedding plants had more the appearance of October than the middle of summer, but the recent fine weather has wrought wonders. Begonias, Calceolarias; Heliotrope, and Lobelia alone seemed to enjoy the unseasonable weather. Sub-tropical and carpet bedding are badly coloured, and have made but little growth. Annuals and perennials generally I have never seen do better. The mixed borders here, which are extensive, are well filled, and are far more satisfactory than they have been in the last two seasons. Hollyhocks, which have escaped the disease here the last three years, are badly infested this season.—EDWIN BECKETT, *Aldenham Park Gardens, Elstree*.

MONTGOMERYSHIRE.

WE are quite three weeks later this year than last (1887). The rainfall of June was 3·75, seventeen wet days; of July, 5·85, twenty-one wet days. We have a good crop of small fruit, but much spoiled by the continued rain and want of sun. Pears on the walls are good, Jargonelles, Clapp's Favourite, Eyewood, Glou Morceau, and Bergamot Esperen especially. Peaches and Nectarines fall off the trees from want of sun. Amsden's June Peach (usually good here) is ripe, but flavourless. Apples much below the average; Plums below the average; early Potatoes diseased; the later sorts have escaped as yet.

Flower garden.—Excepting Calceolarias all bedding stuff has felt the cold nights. July 13th, our minimum was 36°, the 11th, 37°. Herbaceous plants are good this year. The more showy now are the Aconitums, Veronicas, Campanulas, Centaurea macrocephala, and varieties of Sunflower. Among annuals, Scabious, Lupins, Gaillardias, and Godetias have proved best.—H. HUNTLEY, *The Gardens, Powis Castle, Welshpool*.

NOTTINGHAMSHIRE.

THE following is a summary of meteorological observations in these gardens for June and July, 1888:—June—Mean temperature of month, 55·0°; maximum on the 26th, 80·3°; minimum on the 18th, 36·7°. Maximum in the sun on the 26th, 136·9°; minimum on the grass on the 1st, 31·0°. Mean temperature of the air at 9 A.M., 55·6°. Mean temperature of soil 1 foot deep, 55·0°. The thermometer fell below 32° on two nights. Total duration of sunshine in month, 116 hours, or 22 per cent. of possible duration. We had six sunless days. Total rainfall, 1·32 inch. Rain fell on seventeen days. Average velocity of wind, 9·1 miles per hour; velocity did not exceed 400 miles on any day, and fell short of 100 miles on one day. Approximate averages for June:—Mean temperature, 57·1°. Rainfall, 2·26 inches. Sunshine, 162 hours. A very dull month with frequent slight showers, but small total fall; very low day temperature, but not cold nights, a large proportion of N and N.E. wind; closely resembles June, 1886. Vegetation very late. The first June for twenty years we have not gathered ripe Strawberries.

July.—Mean temperature of month, 56·3°. Maximum on the 19th, 72·7°; minimum on the 11th, 39·6°. Maximum in sun on the 19th, 140·3°; minimum on the grass on the 1st, 31·3°. Mean temperature of the air at 9 A.M., 57°. Mean temperature of the soil 1 foot deep, 57·1°. The temperature fell below 32° one night on the grass. Total duration of sunshine in month, 88 hours, or 18 per cent. of possible duration; we had nine sunless days. Total rainfall in month, 4·96 inches; rain fell on twenty-one days. Average velocity of wind, 8·7 miles per hour; velocity exceeded 400 miles on three days, and fell short of 100 miles on five days. Approximate averages for July.—Mean temperature, 61·2°. Rainfall, 2·36 inches. Sunshine (seven years) 172 hours. The coldest and dullest July since observations were commenced here, and the wettest except 1880. The days were especially cold, the mean maximum being 13° lower than last year. The heavy total rainfall was due to a number of moderate falls, and not to any especially heavy ones.—JOSEPH MALLENDER, *Hodsock Priory Gardens, Worksop*.

NORTHAMPTONSHIRE.

THE weather during June and July has been very unseasonable, the temperature generally exceedingly low, the maximum only on two occasions in June reaching 80°, while on six days it did not reach 60°, and twice only 56°. The minimum fell below 50° on twenty-three nights, and on five nights below 40°. Our lowest readings were 31° on the 18th, and 34° on the 14th, the radiation minimum falling to 27° on the 18th. We had rain on thirteen days, the total fall for the month being 1·66 inch. July was much worse than the preceding month, the maximum temperature being equally low, only on one day reaching 76°, and on twenty days it did not reach 70°, and on two days only 55°, the minimum falling below 40° on two nights, the radiation minimum falling as low as 29° on the 1st of the month, and at 9 A.M. on the 11th the temperature was 45°. Rain has fallen on twenty-seven days during the month. The greatest fall in one day was 0·70 inch, and the total for the month 5·95 inches.

The garden crops have suffered through the wet and want of sun. Strawberries, which have been a poor crop except James Veitch, decayed

before getting ripe; the variety named has been exceedingly fine. Cherries have cracked a great deal, but have been a fair crop. Apricots have not made any progress, and are under the average, but all small bush fruits have been plentiful and good. Apples are a fair average crop, and promise to be good. Pears are also fairly good. Peas have grown quite out of character; 3 feet varieties are 6 feet and upwards, but failing to fill their pods. Onions have suffered a great deal with mildew, and early Carrots are much cracked. Potatoes are getting badly diseased, but turn out enormous crops.

Our herbaceous borders have been fairly good, although a great many plants have been much affected by the bad weather. The following are a few which have withstood it best—*Chrysanthemum segetum* and maximum, *Doronicum hybridum*, *Campanula bracteata alba*, *macrantha*, *persicifolia*, and var. *alba*. *Astrantia maxima* and major have been very fine. *Phloxes* have also been wonderfully good, *Lady L. Napier*, a fine white, has been grand; *Delphiniums* have done well, *Madame Rachelet* and *nobilissimum* especially; *Erigeron glabellus* var. *mollis*, *Lychnis diurna* and *dioica* fl.-pl., *Trillium grandiflorum* and sessile, *Trollius americanus* and *giganteus*, *Dianthus caryophyllus* var. and *Atkinsi*, a deep crimson variety, very fine, but rare; *Pyrethrum*, double and single var.; *Oenothera Youngi* has been grand, *Irises* have been splendid, *Eremurus himalaicus* and *robustus* have had fine spikes, and *Dictamnus caucasicus* *giganteus* has been magnificent. In the alpine garden *Onosma taurica* has done well, and *Phyteuma comosum* planted in sandstone has been very fine, *Saponaria ocyroides* Engadine, fine dark var., *Gentians*, *Phloxes*, *Ramondia pyrenaica*, and var. *alba* have all been fine. Of bedding plants we have but very few, tuberous *Begonias* having been much the best.—G. GOLDSMITH, *Floore Gardens, Weedon*.

SURREY.

THE weather in this district during June and July was almost unprecedented for heavy and continuous rains, a very low maximum temperature, and almost a total absence of sunshine. Our rainfall for June was 4.61 inches; on the 26th we had 1.69 inch. This is the greatest quantity in twenty-four hours registered here for the last ten years, and for July the total rainfall reached 5.06 inches.

During the first fortnight of June vegetation was much benefited by the rain, and things in general promised well. After that time the continued bad weather told most deplorably on the more delicate and tender crops. This was especially noticeable in the kitchen garden crops, such as Beet, Lettuce, Onions, Vegetable Marrows, Scarlet Runners, and the better sorts of Peas, the last failing to fill well, and having the appearance of autumn Peas. All the Brassica tribe have done well, Cabbage and Cauliflower being remarkably good, Carrots and Turnips fine. Perennial flowering plants, as a rule, suffered little in growth, but the continued wet was destructive to the flowers. The following have succeeded well here:—*Achillea Ptarmica*, *Alstroemeria aurea*, *Antirrhinum*, *Aquilegias*, *Campanulas*, *Canterbury Bells*, *Centaurea montana*, *Chelone barbata*, *Digitalis*, *Eryngium amethystinum*, *Gaillardia hybrida*, *Gypsophila paniculata*, *Helenium pumilum*, *Hemerocallis flava* and *disticha*, *Iberis sempervirens*, *Iris* of sorts, *Lathyrus latifolius* and *albus*, *Linum flavum*, *Oenothera biennis*, *O. Lamarekiana*, *Pansies*, *Papaver bracteatum* and *orientale*, *Pentstemons*, *Phlox*, *Potentilla*, *Pyrethrum hybridum*, *Rudbeckia Newmanni*, *Spiraea Aruncus*, *S. palmata*, *Sweet William*, tree and herbaceous *Paeonies*. Annuals suffered more severely. These proved satisfactory:—*Cacalia coccinea*, *Candytuft*, *Chrysanthemum coronarium sulphureum*, *C. Burridgeanum*, *C. Dunnetti*, *C. insia bicolor*, *Godetias*, *Lupins*, *Phlox Drummondii*, *Poppies*, and *Senecio elegans*.

Bedding plants, with the exception of the more robust growing *Pelargoniums*, were at a complete standstill, and looked quite autumnal. Carpet bedding failed to fill up, and from want of colour looked anything but what it ought, and succulent plants suffered much from wet and damp. The following *Pelargoniums* were the best here:—*Flower of Spring*, *Marshal McMahon*, *Rev. J. Fenn*, *Star of Fire*, *John Gibbons*, *Rev. F. Atkinson*, and *Mrs. Turner*.—J. RIDOUT, *The Gardens, Woodhatch Lodge, Reigate*.

WARWICKSHIRE.

OWING to our light, dry, sandy soil the crops have not suffered so much as in many other districts from the cold, dull, wet June and July we have just passed through. Of the sixty-one days rain fell more or less on thirty-four; on five days only had we any sunshine worth mentioning; the others were either cold and dull, or cloudy, with blinks of sunshine. The wind for the greater part of that time kept north, north-east, or north-west. Two or three nights about the middle of each month were exceptionally cold for the season, our coldest being on the mornings of the 14th June and 13th July, when we registered 37° and 35° respectively. The greatest heat we registered was on the 26th June and 19th July, when we had 88° and 82° respectively.

Kitchen garden crops look well, only Potatoes and Peas are much overgrown; disease is showing amongst the former, and the latter are affected by mildew to a slight extent.

In the flower garden there has not been much growth, and little or no flowers on the great majority of bedding plants. *Harrison's Musk* has done well, and some Tuberous *Begonias* we have been trying have never been without a few flowers. Such annuals as *Stocks*, *Asters*, *Sweet Peas*, *Mignonette*, and *Lobelias* have continued growing and blooming freely. *Roses* have not turned out so fine as they promised in May, the best buds damping off, but the season has been so much longer for cutting purposes that we have not much room for complaint.—A. CHRISTIE, *Warwick Castle Gardens*.

EVENTS OF THE WEEK.—On Tuesday and Wednesday next, September 4th and 5th, the Warwickshire Horticultural Show in connection with the County Agricultural Show will be held at Rugby. The two following days—i.e., September 5th and 6th, are devoted to the Bath Autumn Show, which being held at the time of the visit of the British Association will be made unusually attractive, substantial prizes being offered for plants and fruit. At Edinburgh the Royal Caledonian Society's Autumn Exhibition will be held on the same dates. The following Friday and Saturday, September 7th and 8th, will be busy days at the Crystal Palace, Sydenham, the Fruit and National Dahlia Shows with a conference of fruit growers being in the programme.

— THE WEATHER.—After a period of fine weather a most disastrous storm occurred on Tuesday last. Heavy rain accompanied by a gale of wind caused considerable devastation in many districts, a culmination of evils. Fruit trees have suffered greatly, farm crops also being much damaged.

— KETTON GEM MELON.—In answer to Mr. Bardney, p. c 170, Mr. W. H. Divers writes—"This variety shows fruit on every lateral, and is a very free cropper. As far as I am able to judge at present the fruit shown at Liverpool was rather above the average size. Three other fruits were grown on the same plant which were not quite so large. As regards habit and constitution we find it very satisfactory."

— THE KENTISH POTATO CROP.—Reports from East Kent state that the Potato crop is damaged by blight, and will be as much as 50 per cent. below the average in yield in some places. A tract of 1000 acres of Potatoes in Mid-Kent, which was under water some time, has been sold at the low price of £7 an acre.

— FRUIT CONFERENCE AT ST. ALBANS.—A Conference on fruit suitable for market purposes will be held in the Corn Exchange, St. Albans, on September the 4th, at 7.30 P.M. The chair will be taken by H. P. Smith, Esq., J.P., ex-Mayor. Papers will be read by Messrs. S. Morgan, J. T. Wright, S. Haliday, J. Cheal, and W. F. Emptage.

— EARLY PURITAN POTATO.—Mr. D. Percival, gardener, The Poplars, Wellingborough, writes:—"In the spring I bought 1 lb. of this new variety, and on the 21st of August I dug and weighed them, when they yielded 110 lbs., many of them being perfect tubers. Some of the heaviest weighed 1½ lb. In my opinion this will be the Potato of the future, the tubers cooking well, and of good quality."

— "AN OLD SUBSCRIBER" wishes to know if any readers can inform him what is the best method of PRESERVING MOUNTAIN ASH BERRIES for use as decoration at Christmas.

— GARDENING APPOINTMENT.—Mr. David Jones desires to state that he has been appointed to the charge of Tilgate Gardens, Crawley, Mr. W. Jordan being now steward of the whole estate.

— IN the report of the SUTTON SHOW last week, Mr. King was credited with having won the first prize for six exotic Ferns, an honour that was really accorded to Mr. Penfold.

— A PERSHORE correspondent, "J. W.," asks if the comparative ABSENCE OF BUTTERFLIES AND WASPS this year has been noticed. He also remarks the trees in his district, as a rule, "have made very little midsummer shoots, although such a dropping time."

— MESSRS. JAMES CARTER & Co. request the insertion of the following paragraph—"We are informed that the whole of the bulbs required by the First Commissioner of Works, and also the Metropolitan Board of Work, for planting in the royal parks, are being supplied by Messrs. James Carter & Co., the Queen's seedsmen."

— "F. G." writes—"Your correspondent 'Merton' mentions in his 'Notes at Kew' the merits of *OLEARIA HAASTI* as a shrub. It may be interesting to your readers to know that a specimen supplied by Messrs. Veitch of Exeter was planted in this churchyard in October, 1881. It is exposed to the full force of the westerly winds, and has thrived

where other so-called hardy shrubs have died. It blossoms profusely every year, and needs no protection here."

— "B. C." sends the following two notes:—"At Holey Hall, the residence of Major Wood, where Mr. T. Irving is gardener, there is a *PICEA NOBILIS* 40 feet high, bearing about 200 cones; some of the branches have sixty on each, the cones measuring 9 to 12 inches long, and the same in circumference."

— "AT LAMBTON CASTLE GARDENS it may be interesting to note that Gros Maroc Grape on a Black Hamburg stock has berries much more elongated and not so round as its usual character. In the same garden the fruit trees in pots bear remarkably well. Beurré Diel and Pitmaston Duchess Pears will weigh 28 to 30 ozs. each, and a fruit of the Apple D. T. Fish (Warner's King) measured 15 inches in circumference. Fine Apples are also noteworthy; suckers planted last March are throwing fine fruits, 4 to 5 lbs. each, and will be ripe in a month or so. Many of these are seedlings."

— **TRADE APPOINTMENT.**—We are informed that Mr. William Napper, late of Osborne House, Alington, has been appointed General Manager to Messrs. Jarman & Co., Chard, Somerset. Mr. Napper was connected with the Old Exeter Nursery for nearly twenty years, and in 1882 found at Newton Abbot the white Passion Flower, which has since become so well known.

— At a recent show in the Crystal Palace an interesting COLLECTION OF HOLLYHOCKS was shown by Mr. J. Blundell, Martell Road, West Dulwich, who has given much attention to these plants with good results. Forty-eight blooms were shown, comprising several promising seedlings, but of the named varieties being Venus, pure white; Princess Beatrice, pale yellow; and Princess of Wales, salmon. They were not large but full, even, and of good form.

— A CORRESPONDENT states that the special feature of the DUBLIN ROYAL HORTICULTURAL SHOW were Dickson's, of Newtownards, new Roses. Her Excellency, the Lady Lieutenant, with the Dukes of Leinster, Abercorn, and a large suite, spent considerable time admiring them. They had the silver medal, and in another class first prize for forty-eight. Their show and fancy Dahlias, forty-eight, had a similar distinction. Grapes were splendidly shown, first prizes going to the Earls of Wicklow and Clancarty.

— **DURANTA PLUMIERI.**—Captain N. W. Turner remarks, "Amongst berry-bearing shrubs for a conservatory this South American one well merits a place. Its long spikes of dark Heliotrope-coloured flowers being succeeded by strings of golden berries, the weight of which causes the branches to droop very gracefully; and as I have known it in Florida to withstand severe frosts, there is little doubt but that being wintered in a very cool house would conduce to the finer display of bloom during the succeeding season."

— A CHILDREN'S FLOWER SHOW was held last week in one of the most densely populated districts of Southwark. Early in the year 200 plants were given out to the children under suitable regulations, of Fuchsias, Musk, Pelargoniums, Tradescantias, and "Creeping Jenny," 117 of these being returned at the Show. Three prizes and some extras were offered in each of the five classes, and when distributing the prizes in the evening the Baroness Burdett Coutts gave an instructive little homily on flowers and flower culture, pointing out the educational value of such a competition.

— "IN the Journal for August 2nd," writes "J. L. B.," "it is stated that Mr. Payne prevents MELONS CANKERING by planting deeply. I have never had any cankered stems since I adopted high planting. None of the stem between the soil and seed-leaf is covered with soil, either during potting or planting out. Each of eighteen Melon plants in 14-inch pots has given two crops of fruit, and as the plants required water two or three times a day it would have been difficult to keep the water off the stems. During the second crop all the water has been poured directly on to the stems to see what effect it would have but it has not made the least difference."

— THE Paris correspondent of a daily paper remarks:—"M. Prilleux has just discovered an infallible REMEDY for the POTATO DISEASE. This is the recipe—Put 13 lbs. of sulphate of copper and the same quantity of chalk into 22 gallons of water and souse the plants with the mixture. An experiment made from the 5th to the 16th instant

saved the diseased plants thus treated, while thirty-two per cent. of those which were left to themselves went to the wall; but the disease must be taken in hand as soon as the first black spots have been perceived on the leaves. The remedy is simple enough, and so is the application, which has been favourably received by the Academy of Sciences."

— MR. W. WAINWRIGHT, 1, West Lane, Eccles Old Road, near Manchester, sends the following WARNING TO GARDENERS:—"About five weeks ago a man called on me representing himself as a gardener out of employment who had just recently lost his wife. I gave him assistance (both food and money), and he called several times during one week. The last time (July 13th) he said that a leading gentleman who is well known in Manchester had obtained him a situation, and as he begged hard for more money I lent him £2. He promised to write, also to come and see me, which he failed to do, and from inquiries since made I find all that he said to be false, and that he has defrauded others besides myself. He has given the name of McBride."

— LAST Saturday, at the usual weekly meeting of the members of the WAKEFIELD PAXTON SOCIETY, Mr. Rigg presided, and Mr. Arthur Goldthorp was in the vice-chair. There was an average attendance of the members. Mr. T. Gartery of Rotherham, who has previously given essays at the Wakefield Society, read an interesting and thoroughly practical paper on "Tomatoes," and some fine specimens were exhibited. Mr. Gartery treated his subject well, and gave much valuable information and many useful hints to his fellow professional gardeners, and also to amateurs. An interesting discussion followed the reading of the paper, during which reference was made to the growing popularity of the Tomato. A hearty vote of thanks was given to Mr. Gartery.

— As announced recently, a party of members of the NATIONAL CHRYSANTHEMUM SOCIETY and their friends visited Baron Schröder's gardens, The Dell, Egham, on Friday last, August 24th. About seventy-five assembled at Waterloo Station, and several others were met at Egham, making the total party over eighty. Several hours were profitably and agreeably spent in inspecting the valuable collection of plants, the fruit houses, and the admirably kept gardens under the guidance of the gardener, Mr. Ballantine, and his assistants. The party then adjourned to the "Angler's Rest Hotel" for tea-luncheon, and after a pleasant day's outing, marred only by one rather heavy shower in the evening, they left Egham Station for London at 8.30 P.M. The arrangements for the excursion were all made by Mr. W. Holmes, who proved a genial and considerate conductor.

— THE usual fortnightly meeting of the WALKLEY (SHEFFIELD) ANATEUR FLORAL AND HORTICULTURAL SOCIETY was held on Friday evening last at the Society's rooms, the President (Mr. T. B. Hague) in the chair. A remarkably fine collection of Roses (cut blooms) was exhibited by Mr. Duncan Gilmour, jun., for which a unanimous vote of thanks was passed by the meeting. Excellent stands of cut Roses were also shown by the President and by Mr. J. Shipman. Plants, cut flowers, and vegetables were shown by Messrs. Ash, Jarvis (Secretary), Herringshaw, Cuckson, and others. An exhaustive and valuable paper was read by Mr. Jno. Haigh on "The Fertilisation of Flowers," which gave much satisfaction, and induced a very interesting discussion. A vote of thanks to the essayist was moved by Mr. Shipman, seconded by Mr. Cuckson, supported by Messrs. W. K. Woodcock, and Councillor Outram, and carried with acclamation.

— A CHINESE PAGODA IN FLOWERS.—Thousands of visitors have been to the Danvers Hospital grounds (at Boston) the past few weeks, and the horse-cars carry great loads daily, extra trips being run on visiting days—Mondays and Wednesdays. The main object held in view by the many strangers is to see the marvellous flower beds designed and arranged by the florist and gardener, Ettore Tassinari. The largest design is a Chinese Pagoda, 17 feet high, with a dome supported by six pillars, and archway beneath high enough to pass under without stooping. There are three fountains and thirty varieties of plants. The front of the base has a calendar of growing plants in portable boxes, and the back a shield, flags, and draperies. Florists from far and near have pronounced this design the best they ever saw. A solar clock or sundial attracts much attention, as it accurately tells the time of day by a shadow cast by a pole of growing plants placed at an angle of 47°, and pointing to the north star. The shadow falls on floral numerals in the rim of a horseshoe-shaped bed of plants.—(*American Paper.*)

— A CORRESPONDENT writes as follows on THE ACME WEED KILLER which has been advertised:—"In April we gave several walks a good dressing of it, which in a few days after its application destroyed every vestige of vegetation, and no weeds have been seen since on that part of the garden. It leaves the walk clean, bright, and firm, and there is, in the end, a considerable saving of expense over hoeing and hand-weeding. For some previous years we have been in the habit of using No. 5 carbolic acid largely diluted with water, but prefer the Acme as being cheaper, and free of that objectionable smell which is left for several days after applying carbolic acid. When applying the preparation great care must be taken not to allow it to come in contact with Box or grass edging. I have, during hot dry weather, when the paths have been very hard and dry, applied a few cans of clear water a few hours prior to using. This softens the top, and the mixture readily soaks down to the roots of the weeds, destroying them, and giving us the greatest satisfaction."

— A VEGETARIAN CONFERENCE. — The London Vegetarian Society invited last Monday to one of their "Fruit and Cake Conferences," the members of the London Press, and about forty-five accepted the invitation. After the repast, consisting of fruits of various sorts, salads, cold savouries, and various cereal foods and sweets, Mr. Alderman H. Phillips, of West Ham, presided at the Conference. In commencing his address, the Chairman expressed his deep regret at the absence of Mr. Hills, their President, which was a great loss for all present. After giving a few of the leading reasons for upholding the non-flesh diet, Mr. Phillips said vegetarianism did not mean eating vegetables any more than librarian meant eating libraries. Fruit and cereal foods were, he contended, the proper food for man, because Science classed us with the fruit-eating division of animals. Mr. James Burns, in an eloquent address, spoke of the pressure to which Pressmen were subject from a lengthened experience, and of his strong convictions of the immense advantage of a diet entirely free from all stimulants, solid or liquid. Mr. Manning, the Organising Secretary, closed the meeting by urging all to give a trial to a movement that made out so good a *prima facie* case for itself.

— DR. HOSKINS, writing in the *American Garden* on AMERICAN PLUMS, says, "The European Plum, from which our cultivated varieties is derived, is said to have its origin from the uneatable Sloe. Now, the American wild Plum is by no means an uneatable fruit. Some of the wildlings are really good, and it is strange that so little has been done in the way of cultivation, crossing, and the growth of seedlings to improve the race. Interest in them is, however, increasing, and before long we shall be apt to see marked gains, such as have been made with our native Grapes. Mr. Munson of Denison, Tex., is much interested in this fruit, but I fear that the Cicasaw type will not prove so well adapted to northern culture as the two northern types—that of Canada and that of the West. These two are not alike, the western Plum being nearer the European in firmness of flesh and plumpness of seed. The Canada type has a large and very flat seed, and in most cases the flesh is soft and watery. But for preserves and jellies these wild Plums are on the whole superior to the foreign sorts, having a brisk flavour, approaching that of the Peach. They also have the merit of extreme hardness, being rarely harmed by any amount of cold. The colour is in shades of yellow and red, and the size is sometimes quite large. Selections have been made of varieties with pretty firm flesh, and in other ways showing a tendency to vary in the direction of improvement. The worst fault about the western type is the tendency, like that in the Strawberry, to be defective in the staminate element, resulting in barrenness, unless care is taken to plant varieties with good stamens close by. There ought to be no difficulty in crossing the various types together, or with the European Plum, and when a decided break is made seedlings varying widely are pretty sure to appear, from which selections can be made in the directions desired for improvement. Many of these native Plums are able to resist the attack of the curculio and produce large crops of fruit, which is a great point in their favour."

A SAD CASE.

By your very kind permission, I beg to ask the respectful attention of your numerous readers to the case of Joseph Richardson. About three years ago he was head gardener to J. S. Wheatley, Esq., Calverton Hall. Recovering from diphtheria, his left knee diseased, and having a wife and six children he and his family had to depend upon his small

club pay and the aid of friends. At the General Hospital, Nottingham, it was found necessary to amputate the leg, but owing to the disease he was discharged as incurable. Through the kindness of other friends he was taken to the Llandudno Hospital, where his thigh was amputated. The poor man is now in great distress, and needs help. I fear he is in a consumption. Formerly he contributed certain articles to your valuable Journal, and may be known to some of your readers, who, I am sure, in human sympathy, will help this most deserving case.

Subscriptions on behalf of J. R. will be received by—W. FIELD NEWMAN, *Endowed School, Calverton, Notts*; or by E. STEWARD, *Sec. Notts Horticultural Society, 2, Exchange Row, Nottingham*.

[The occasional short contributions of Mr. J. Richardson to this Journal a few years ago led us to regard him as an intelligent, educated, practical gardener, and we commend his case to the sympathy of our readers. Members of gardeners' associations might perhaps collect a few shillings at their meetings to assist a brother gardener in such dire distress; and small collections may possibly be made in some private gardens.]

ROYAL HORTICULTURAL SOCIETY.

AUGUST 28TH.

THE greater portion of the usual available space in the Drill Hall, James Street, Westminster, was occupied with exhibits on Tuesday last, Gladioli from Langport, hardy flowers from Tottenham, Dahlias from Crawley, and Orchids with other choice plants from Upper Holloway constituting the chief attractions. The weather was, however, most unfavourable and the attendance of visitors small.

FRUIT COMMITTEE.—Present: T. Francis Rivers, Esq., in the chair, and Messrs. J. Lee, R. D. Blackmore, T. J. Saltmarsh, G. W. Cummins, J. Burnett, W. Marshall, and Peter Barr.

Mr. W. Roupell, Roupell Park, was awarded a cultural commendation for the Strawberry and several Frontignan varieties of Grapes, also clean bunches of Duke of Buccleuch, with fine berries. Mr. Owen Thomas, Chatsworth Gardens, sent small bunches of a seedling black Grape with small globular berries. It was considered to be like Early Ascot in appearance, the flavour was sweet, but devoid of special character, and the skin was thick. It is said to be earlier than Black Hamburgh. Mr. Whillans, Blenheim Gardens, Woodstock, exhibited a neat well netted Melon, which was not ripe, and an opinion was deferred to the next meeting. Several other Melons were also shown; one from Mr. Boston was decayed, and another, named Standard, from Messrs. Veitch & Sons, Chelsea, was not in its best condition. A vote of thanks was accorded to the last named firm for a collection of fruits, including very large handsome fruits of Sea Eagle Peaches, Plums, Apples, Pears, Morello Cherries, and Quatre Saisons Strawberries.

FLORAL COMMITTEE.—Present: The Rev. W. Wilks in the chair, and Messrs. Shirley Hibberd, H. Herbst, J. Fraser, J. Walker, W. Holmes, W. Goldring, R. Dean, B. Wynne, H. Ballantine, J. Dominy, H. M. Pollett, J. O'Brien, E. Hill, and Dr. M. T. Masters.

A silver-gilt Banksian medal was awarded to Mr. B. S. Williams, Upper Holloway, for a handsome and valuable group of flowering and fine-foliage stove and greenhouse plants. Conspicuous amongst the Orchids were some beautiful examples of *Cypripediums*, such as *C. Ashburtoniae* and its two varieties *expansum* and *superbum*, *C. Dayanum*, the new *C. Sanderianum*, *C. superbium*, *C. oenanthe*, and a grand form of the richly coloured *C. oenanthe superbum*, also the most valuable *C. tessellatum porphyreum* with three flowers on one spike. *Laelia Perrini*, *Cattleya gigas*, *C. Dowiana*, *Dendrobium Goldei* and *D. formosum* were all represented by well grown specimens, such as visitors to Upper Holloway are accustomed to seeing. The autumn-flowering *Amaryllis* Mrs. W. Lee, one of the *reticulata* hybrids, was noteworthy, also the rosy crimson *Anthurium leodinense*, with finely formed broad spathes; *Griffinia Blumenavia*, a graceful stove bulbous plant bearing blue and white flowers, and *Adiantum colpodese roscum*, having the young fronds of a bright rosy colour. Collections of *Droseras* and *Dionaeas* and of *Sarracenias* completed the group. The *Sarracenias* were excellently represented by small but characteristic and well coloured plants, the varieties shown being *Williamsi*, *hybrida*, *Wilsoni*, *illustrata*, very distinct, green and red; *Tolliana*, *Chelsoni*, *variolaris*; and *Mitchelliana*, deep red.

Messrs. Kelway & Son, Langport, had a brilliant group of *Delphiniums*, *Gaillardias*, and *Gladioli*, the latter numbering some hundreds of handsome massive spikes that seemed to have been unaffected by the weather. Several certificates were awarded, and a silver Banksian medal were adjudged for the whole group. Messrs. H. Cannell & Sons, Swanley, sent a collection of double and single *Begonias*, mostly the former, described as having been raised from seed sown February 11th, 1888 (bronze medal). Certificates were awarded for several varieties which are described below. Messrs. Cheal & Son, Crawley, exhibited a group of *Cactus*, *Pompon*, and single *Dahlias*, comprising some excellent varieties and many novelties, the best being selected for certificates (bronze medal). Mr. T. S. Ware, Tottenham, as usual had a varied and beautiful group of hardy flowers, including single and *Pompon Dahlias*, *Lilies*, *Gladioli*, *Iceland Poppies*, &c. (bronze medal). Mr. F. T. Smith, West Dulwich, showed a collection of *Hollyhocks* and *Phloxes*. Mr. R. Dean, Ealing, had some large trusses of *Phloxes*. Messrs. Munro and Ferguson, Edinburgh, sent a double white *Matricaria inodora* named *Snowflake*. Messrs. R. Veitch & Son, Exeter, showed a pale yellow *Sunflower* named *Primrose Dame*, and Messrs. Walsham & Son, Scarborough, sent flowers of *Carnation Juliet*, a peculiar pale buff tint.

Mr. W. Roupell exhibited a fine plant of *Funkia grandiflora* with eight spikes of long white flowers and bright green narrow leaves, which contrasted well with plants of the brilliant *Lobelia splendens*. A. Le Doux, Esq., Langdon House, East Moulsey (gardener, Mr. W. Rhynes), showed a variety of *Cattleya Loddigesi*, the sepals and petals soft mauve, the lip pale yellow; the plant had two spikes of four flowers each. Mr. J. T. West, gardener to W. Keith, Esq., Brentwood, showed some seedling *Dahlias*. Mr. Smee sent a plant of *Lycaste tetragona*, having brownish sepals and petals and purple lip. A vote of thanks was accorded to Messrs. Veitch & Sons, Chelsea, for grand blooms of the orange and lemon coloured African Marigold with Veitch's striped French Marigolds. From the Royal Horticultural Society's Gardens, Chiswick, came a large collection of Stocks and Asters with two fine spikes of *Hedychium Gardnerianum*.

PLANTS CERTIFICATED.

Adiantum versailleuse (B. S. Williams).—A variety of the Ludde-mannianum type, dwarf and compact, the fronds much bunched at the apex, the pinnules clustered and bright green.

Odontoglossum Karwinski (Mr. Robbins, gardener to W. Vanner, Esq., Camden Wood, Chislehurst).—A strong growing Orchid, with a panicle nearly 4 feet long, the sepals and petals barred with brown, the lip deep purple, fading to nearly white at the margin.

Disa lacera (A. H. Smee, Esq.).—One of the "Blue Disas," with a tall slender scape bearing five small flowers, three expanded, the upper sepal hooded, and with the two lower bluish purple. The lip is purple and fringed. It was awarded a botanical certificate.

Delphinium Horus (Kelway & Sons).—A bold handsome variety, flowers large, deep blue with a white centre.

Canna Capriciense (Cannell & Sons).—A showy variety, the flowers large orange scarlet edged with yellow.

Canna Francisque Morel (H. Cannell & Sons, and T. S. Ware).—Flowers large, with broad segments, deep crimson.

Canna Madame Just (Cannell & Sons).—Bright orange red, very handsome and distinct colour.

Canna Amiral Courbet (H. Cannell & Sons).—Very fine, yellow, spotted red; one of the most handsome.

Begonia The Lady (H. Cannell & Sons).—A single tuberous variety, the flowers of good shape, the petals broad and rounded, pure white.

Begonia Mrs. Lascelles (H. Cannell & Sons).—A double tuberous variety, with exceedingly large flowers, nearly 5 inches in diameter, the petals broad, bright clear rose, white centre.

Begonia Mrs. Lynch (H. Cannell & Sons).—A double tuberous Begonia, the flowers of good form, pale soft pink, the margins neatly undulated.

New Gladioli (Kelway).—*Bullion*, buff yellow, with a few crimson streaks, distinct; *Mayo*, rich crimson, white centre, large flowers and spike; *Nicon*, soft blush and buff, and a few rosy streaks, flowers well formed; *Magus*, delicate blush, nearly white, streaked with purple in the centre, very handsome; *Cebes*, crimson purple, fine flower and spike.

Gaillardia splendidissima plenissima (Kelway & Son).—Very full, double, with numerous small florets, gold and red.

Dahlia Beauty of Brentwood (Mr. West, gardener to W. Keith, Esq., Brentwood).—This was described as a seedling from Juarez, with larger footstalks, free and of fine habit. The colour is a bright purplish crimson, rich and distinct.

Trichocentrum Ella (G. T. White).—A botanical certificate was awarded for this Orchid, the flowers of which are like those of a small *Odontoglossum*, white with purple spots, lip yellowish with small crimson dots.

Dahlia Duchess of Albany (J. Cheal & Sons).—An exceptionally distinct single variety of quite novel colours, soft mauve edged with pale buff brown, the florets broad.

Dahlia Victoria (J. Cheal & Sons).—Single; the florets neat and spreading; white edged with dark scarlet.

Campanula isophylla alba (T. S. Ware).—This differs only from the ordinary type in the flowers being pure white; it is free and graceful in habit.

At a general meeting held in the afternoon, Rev. W. Wilks, Hon. Sec., in the chair, the following candidates were duly elected Fellows—viz., Miss Browning Hall, Thomas Butcher, S. C. Clay, Edward Cumberlege, H. M. Cumberlege, James H. Forwalk, C. A. Harris, C. B. Saunders, A. W. Tait, H. A. Thompson, Theodore Waterhouse, John Watkins, A. L. Wigan, and Mrs. Spencer; and R. B. Gall as Associate.

CALENDULA PLUVIALIS.

THOUGH well entitled to rank amongst old-fashioned plants, this useful hardy annual is by no means a familiar occupant of modern gardens. Under the name given above it was cultivated by Philip Miller in 1726, and it seems to have been included in the Kew collection since the time Aiton's "*Hortus Kewensis*" appeared—namely, in 1789. In that garden a portion of one of the Compositæ beds is still annually devoted to it, and from the specimen there grown our sketch (fig. 22) has been prepared. The flower heads are about the size of the common Marigold, the upper surface of the ray florets pure white, the leaves purplish, they are freely produced; the plant is of moderate height, the

leaves narrow and slightly serrated. It was long ago noticed that the flower heads "open when the sun shines, closing every evening, and remaining closed in dull weather." It has also been discovered that "when the flower decays it hangs down during the growth of the seeds but when they are fully ripe the peduncle is raised again, so that the heads stand upright."

Easily raised from seed and growing readily in almost any soil that is not too heavy it is well worth a place in any garden. It is a native of

Fig. 22.—CALENDULA PLUVIALIS.

the Cape of Good Hope, and is sometimes seen under the generic name *Dimorphotheca*.

HORTICULTURAL SHOWS.

SHANKLIN, ISLE OF WIGHT.—AUGUST 15TH.

THE eleventh annual Exhibition of the above Society was held in the very beautiful grounds of "Rylstone," by kind permission of Mons. and Madame Spartali. The weather was most unfavourable, rain pouring in torrents at intervals all the morning. The Exhibition was kept open another day to give the many visitors in town another opportunity of visiting the Show. Three large marquees were provided for the various exhibits, the plant and vegetable classes being well filled, but there was a great falling off this year in the fruit classes. The chief exhibitors in the plant classes were Mr. G. Wilkins, gardener to S. W. Ridley, Esq., St. Helens, who showed amongst others a fine specimen of *Asparagus plumosus nanus* and *Cissus discolor*. Mr. Stickland, gardener to Mons. Spartali, had some splendid Cockcombs, dwarf and good, also good Zonal Pelargoniums and Tuberous Begonias, stove and greenhouse Ferns, &c. Mr. G. Dale, gardener to W. Gibbs, Esq., was first with fine foliage plants, and Mr. Geddes, gardener to G. F. Coster, Esq., took many prizes in the plant classes.

Mr. J. Banting, florist, took highest honours for a bouquet and

buttonholes, and second for ladies' sprays, and also showed a splendid cross of *Eucharis* and other choice flowers not for competition, all characterised by tasteful and elegant arrangement. Cut blooms of Zonal Pelargoniums, Asters, Marigolds, Zinnias, Cactus and Pompon Dahlias, Phloxes, and Gladioli were all well represented in their several classes, and formed an attractive feature. With one or two exceptions the fruit was only moderate, the season being all against the ripening. On the other hand the vegetables were extraordinarily good, and brought out strong competition in the professional, amateur, and cottagers' classes. The leading variety of kidney Potatoes were Pigant's Improved, exhibited by Mr. Pionchon. International Kidney, Edgecote Purple, and Snowdrop were also well represented. In the rounds Schoolmaster was largely shown, and a good dish of Sutton's Seedling was very attractive.

It is to be hoped that the exertions of Mr. W. Gibbs, the President, the Hon. Sec., Mr. J. Silsbury, and the members of the Committee will be rewarded with extra support to enable them to show a clear balance-sheet.—C. O.

TROWBRIDGE—AUGUST 22ND.

THERE are few older Societies than this, and if the annual Exhibition is not very high class throughout, there is always much that is attractive and worthy of notice. Nothing in the shape of an innovation is ever attempted, the prize schedule year after year being only slightly varied. In spite of this and the moderate prizes offered for plants especially, quite a large show is brought together, while visitors from many miles around flock in great numbers to Trowbridge for the day. It is one the principal events of the year in the district, and with ordinarily fair weather success is never doubted. Mr. James Huntley has long and ably filled the post of Honorary Secretary, and a large Committee assist him to the best of their ability.

Fuchsias are always very fine at these Shows, and on this occasion they were quite as numerous and good as usual. With six specimens Mr. Tucker, gardener to Major W. P. Clark, Trowbridge, was well first, having grand pyramids not less than 8 feet high, most of the varieties being Lye's Seedling. Mr. H. Pocock, gardener to J. P. Haden, Esq., Trowbridge, was a good second. Mr. J. Matthews, gardener to W. R. Brown, Esq., Trowbridge, was first for four specimens, these being wonderfully fine and well flowered, the second prize in this instance going to Mr. Tucker. The best nine stove and greenhouse flowering plants were staged by Mr. Tucker, who had well flowered medium-sized specimens of popular kinds, Mr. J. Matthews being a good second. Mr. Pocock was first for six plants, and Mr. Tucker second; and for three specimens Mr. J. Matthews was well first, the second prize going to Mr. J. Currey, gardener to Colonel Pepper, Salisbury. The last named was the most successful with fine-foliage plants, Mr. W. C. Drummond, Bath, taking the second prizes. The best Heaths were shown by Mr. J. F. Mould, Pewsey, the second prize going to Mr. J. Matthews. Mr. G. Pymm, gardener to Mrs. Gouldsmith, Trowbridge, was the only exhibitor of Orchids, and was rightly awarded the first prize. Grand Ferns were staged, the competition as usual being keen. Mr. Tucker was awarded the first prize, his *Adiantums* and *Gymnogrammas* being especially noteworthy. Equal seconds were given to Mr. J. Coke, gardener to A. P. Stancombe, Esq., Trowbridge, and Mr. H. Pocock, both having several well grown plants in their respective groups. Mr. Matthews had the best *Coleuses* and *Caladiums*, Mr. Tucker the best *Achimenes* and *Pelargoniums*; Mr. C. Richmond, gardener to G. L. Palmer, Esq., Trowbridge, the best double and single Tuberous *Begonias* and *Gloxinias*; and the Rev. C. C. Layard, Bath, the best *Cockscombs*, *Petunias*, and *Verbenas*, the competition being close and good in nearly every instance.

Cut flowers, including *Roses*, *Dahlias*, *Asters*, and *Carnations*, are always extensively and well shown at Trowbridge. In the amateurs' classes for the former, Mr. Campbell, gardener to S. P. Budd, Esq., Bath, was the most successful competitor, and in the open classes he was also first for twenty-four single blooms. Mr. J. Mattock, Oxford, took the lead with twelve triplets, Messrs. Keynes, Williams & Co., Salisbury, being a close second. The latter firm were also second for twenty-four singles, and they were the most successful in several classes for *Dahlias*. Mr. G. Humphries, Chippenham, also staged several excellent stands of *Dahlias*, and was awarded the second prizes. The most successful in the various classes for *Asters* were Messrs. G. Cooling & Son, Bath; G. S. Walters, Calne; G. Garraway, Bath; and W. Jones, Bath. Messrs. G. & F. Hooper, Bath, had the best *Carnations* and *Pansies*, and with Gladioli Miss C. Walters, Calne, and Mr. G. S. Walters were the prize-winners. Several classes were provided for vases or epergnes of flowers, as well as hand bouquets and wreaths, and in all of them the competition was very keen. Some of the most successful were Messrs. M. Hookings, Clifton; T. Meakins, C. Winstone, Clifton; E. T. Hill and Miss L. Durbin, Bath.

Fruit and vegetables were plentiful and of good average quality. The best collection of ten dishes of the former was staged by Mr. A. Miller, gardener to W. H. Long, Esq., Rood Ashton, who had a creditable display. With six dishes, Mr. W. Iggulden, gardener to the Earl of Cork, Frome, was first, and Mr. G. Pymm second, both having good collections. Mr. Miller had the best Pine Apple, though the Judges awarded an equal first to Mr. M. Hookings for a small Smooth Cayenne which happened to be the ripest. Several classes were provided for Grapes, all of which were well filled. The best black Grapes, excluding Muscats, were staged by Mr. J. Gibson, gardener to Earl Cowley, Chippenham, who had very good well-finished bunches of Black Hamburgh. Mr. A. Miller was second for the same variety, and Mr. Iggulden had a third for well finished Gros Maroc. In a corresponding class for white

Grapes Mr. Iggulden was first with well ripened Buckland Sweetwater, and Mr. J. Attwell, gardener to T. B. Brain, Esq., second. Mr. Iggulden was also first for Muscat of Alexandria, the second prize going to W. Shelton, gardener to W. R. Wait, Esq., Bristol. Mr. J. Gibson staged very good Madresfield Court in the class for black Muscats, and was first, Mr. Attwell being second with the same variety. There were fairly good Melons, the best green-fleshed variety, unnamed, being staged by Mr. W. Atkins, gardener to J. H. Foley, Esq., Limpley, Stoke; the Rev. C. C. Layard was second. In the class for a scarlet-flesh variety Mr. Iggulden was first with a heavy and excellent fruit of Blenheim Orange, Mr. M. Hookings being second. Messrs. J. Bishop, W. Iggulden, C. J. Jones, A. Miller, W. Atkins, W. Evry, and E. J. Greenland were the most successful in various classes for Peaches, Nectarines, Apricots, and other fruits, the competition being fairly good throughout. Mr. G. Garraway was the most successful with vegetables, Mr. A. Miller also having a capital collection. Mr. W. Strugnell, gardener to A. R. Bailly, Esq., Frome, was first for a dish of Tomatoes, staging good fruit of Mikado, the second prize going to Mr. J. Gibson. The list of other prominent prizewinners included Messrs. F. Stokes, E. G. Lush, A. Gibson, R. O. Hale, J. Hudd, W. Bristol, and N. Elkins.

SHREWSBURY.

THE annual Exhibition of the Shropshire Horticultural Society, better known as the "Shrewsbury Show," was held in the Quarry Grounds of that town on August 22nd and 23rd. The success of this Society has become familiar to horticulturists, and great as that has been in former years that of this year has far surpassed all previous records. The entries numbered 2800, being 360 more than in 1887. It will be admitted this is a great stride, but other important features have kept pace with it; and the gate money, to which all show officials look with interest, came up to unprecedented figures. On the first day of the Show the attendance is largely composed of subscribers, and the gate money on that day is not regarded as decisive, although some societies would consider it important, as in 1887 £130 17s. 8d. was taken, whilst on the first day of this year it amounted to £247 1s. 3d.; but it is the second day which extends the coffers, and the figures are almost startling. They are as follows:—1887, £1142 17s. 6d.; 1888, £1307 4s. 6d.! And to this must be added some hundreds of pounds for tickets sold previous to the Show, which brings the gate money of this year close upon £2000. This, as may be understood, is not accomplished without a prodigious amount of hard work; but it is admirably executed, and the energy and courtesy of Messrs. Adnitt and Naunton, the indefatigable Hon. Secs., as well as that of the Committee generally, increase with the development of the Show. The arrangements were excellent, and every detail was carried out without a hitch. Results speak so loudly in this case that it is almost superfluous for us to offer the officials our hearty congratulations, but they merit every word that can be said in their favour. The town and district have derived many benefits from the surplus funds of the Society, and generosity is still part of their programme. We were by no means inclined to find fault with the amount of money given in prizes. It is handsome, but additions to some of the existing prizes and a few more classes would not be harmful, but it is only right that they should extend with the development of the Show. Indeed, under such a flourishing Society everything ought to be included and liberally provided for that is in any way connected with the advancement of horticulture.

PLANTS.—A huge tent contained the leading classes. The prizes of £25, £20, and £15 brought some magnificent specimens. Mr. Cypher of Cheltenham was awarded first prize for the strongest twenty we have yet seen him stage at this Show. Evidently opposition was anticipated, and good as the second plants from Mr. Roberts, gardener to A. Nicholson, Esq., Leek, were, there was a difference. Mr. Cypher's were in superb foliage and flower, and comprised *Latania borbonica*, *Keatia Fosteriana*, *K. australis*, *Cycas revoluta*, *C. circinalis*, *Cordyline indivisa*, *Dasyllirion acrotrichum*, *Croton Queen Victoria*, *C. Neumannii*, *Erica Marnockiana*, *E. Thompsoni*, *E. Irbyana*, *E. ampullacea Barnesi*, *Allamanda Hendersoni*, *A. nobilis*, *Ixora Pilgrimi*, *I. Regina*, *Phenacoma prolifera Barnesi*, and *Statice profusa*. The best from Mr. Roberts were *Croton Queen Victoria*, *C. majesticus*, *C. angustifolius*, *Erica Irbyana*, *Dipladenia amabilis*, *Ixora coccinea*, and *Latania borbonica*. Mr. Finch, Oswestry, was third, his best being *Erica Lindleyana*, *Croton Mortii*, and *Dipladenia amabilis*. In the class for nine stove and greenhouse plants Messrs. Pritchard & Sons, nurserymen, Shrewsbury, were a good first with fine grown specimens of *Erica ampullacea Williamsi*, *Gleichenia dichotoma*, *Clerodendron Thompsonianum*, *Allamanda Hendersoni*, *Croton Queen Victoria*, *Davallia Mooreana*, *Lapageria alba*, and *Latania borbonica*. Mr. Farrant, gardener to Mrs. Jason, Shrewsbury, was second and third. Mr. Farrant was also first for six stove and greenhouse plants, confined to gardens in Salop and Montgomery, but there was nothing remarkable in this class. Ferns followed, and Mr. Roberts gained the first place with good specimens of *Todea superba*, *Davallia Mooreana*, *Aspidium concinnum*, *Microlepia hirta cristata*, *Adiantum concinnum*, *Cyathea dealbata*, and *Hymenophyllum demissum*. Mr. Lambert, gardener to Col. Wingfield, Onslow, Shrewsbury, was a close second. In the gardeners' class for the same number Mr. Jason was first; Mr. Milner, gardener to the Rev. J. D. Corbet, Sundorne Castle, Shrewsbury, second; and Mr. Lambert third. The class for six plants in flower, Orchids excluded, was well filled, Mr. Cypher being first with *Ixora Fraseri*, *Allamanda nobilis*, *Statice profusa*, *Erica Marnockiana*, *E. ferruginea major*, and *E. æmula*. Mr. Roberts and Mr. Finch second and third.

Palms were very effective, Mr. Roberts, Mr. Cypher, and Messrs. Pritchard & Sons winning the prizes with fine plants, amongst which *Latania borbonica*, *Kentia Fosteriana*, *K. Belmorcana*, *Thrinax elegans*, *T. argentea*, and *Seafortia elegans* were conspicuous. *Dracænas* were well shown by Mr. Lambert and Mr. Milner. The first prize *Caladiums* from Messrs. Pritchard were especially good, larger and better coloured than the second one from Mr. Farrant. *Colcus* were not particularly good, Mr. J. Barker, Shrewsbury, showing the best; but *Fuchsias* were attractive, the finest coming from Messrs. Pritchard. *Begonias* from Mr. J. Owen, The Cedars, and General Jenkins, Cruckton, were well grown, and the double and Zonal *Pelargoniums* were extremely showy. The groups arranged for effect in a space of 100 square feet commanded much attention, as they always do when well arranged, but only two were entered, both from Messrs. Pritchard & Sons. The first prize was withheld, the second and third being awarded. Both groups were tastefully arranged, and merited the higher awards. Withholding prizes is a discouraging practice. The class for twelve plants for table decoration was a very interesting one, Mr. Lambert being first and second with fresh little Palms, *Crotons*, and *Dracænas*, &c.; and Mr. Dick, Thames Ditton, third.

Plants from amateurs were arranged down the middle of the fruit tent, and although lacking the dimensions of many of the specimens shown in the first one, some fine and well-grown plants were to be found there. For six stove and greenhouse plants, Mr. Burr, Oaklands, Shrewsbury, came first with *Bougainvillea glabra*, *Allamanda Hendersoni*, *Lapageria rosea*, *Statice profusa*, *Stephanotis floribunda*, and an *Ixora*, all well bloomed. Mr. Barker had the best Ferns and *Colcus*; Mrs. Wace, College Hill, the best *Fuchsias*; and Mr. H. Owen the best *Pelargoniums*. *Achimenes* were small, and *Gloxinias* past their best. *Petunias* were extra good, Miss Edith Brooks, Council House, winning first prize with four grand doubles. Some of the amateur collections reduced their chances of winning through having one or more very poor plants amongst the good ones, but the display regarded collectively was exceedingly effective.

CUT FLOWERS.—Some of these bore traces of being unmercifully treated by the weather, but others had been more fortunate, and all classes contained some good blooms. Messrs. Perkins & Sons, Coventry, were first for twenty-four cut *Roses*. These were large and bright, a few of the very best being *Alfred Colomb*, *La France*, *Eclair*, *Maréchal Niel*, *Madame Victor Verdier*, *Le Havre*, *Horace Vernet*, *E. Y. Teas*, and *Louis Van Houtte*. Mr. Murrell, nurseryman, Shrewsbury, was a close and good second, Her Majesty, A. K. Williams, Marie Van Houtte, and Marie Baumann being the leading varieties. The amateur *Rose* classes were well filled, and close to these the *Dahlias* were staged in great numbers. In the class for thirty-six varieties Messrs. Heath & Son, Cheltenham, were first with splendid blooms. Conspicuous amongst these were Mrs. Gladstone, Joseph Service, Joseph Green, Mrs. W. Slack, John Henshaw, Jas. Ashby, Mrs. Langtry, Prince Bismarck, Jas. Stevens, and Thomas Hobbs. Mr. Shaw, Kidderminster, was second, and Messrs. Heath third. This was a good class, as was also that for twenty-four *Dahlias*, Messrs. Heath and Mr. Shaw again winning, with Mr. E. Wright third. Single *Dahlias* were less attractive, the classes not being over well filled. Mr. W. Shaw won first and second for eighteen *Gladiolus* spikes, good in form and colour. Many of the *Asters* were damaged by the weather. *Phloxes* were showy, but small in spike, and *Carnations* and *Picotees* were grand. Messrs. Hans Niemand & Co., Birmingham, were the best and most fortunate exhibitors. Their twelve first prize *Carnations* consisted of H. Cannell, J. D. Hextall, J. Douglas, George, Squire Potts, Lady Curzon, Sarah Payne, Admiral Curzon, Rose of Stapleford, Joseph Lakin, and Mrs. Erskin Wemyss—a grand stand. Mr. A. E. W. Darby, Little Ness, Shrewsbury, was second, and Mr. W. Adams third. In *Picotees* Messrs. Niemand were also first with a superb stand of the following—Burnette, Beauty of Plumstead, Mrs. Sharp, Zerlina, Mrs. Lord, Mrs. Horner, Mrs. Rudd, Dr. Epps, Favourite, Mrs. A. Chancellor, Clara Penson, and Campanini. Mr. Darby and Mr. Adams were the other winners.

Another attraction close to these were the bunches of stove or greenhouse flowers, and Mr. Blair, gardener to the Duke of Sutherland, Trentham, was awarded first with a magnificent collection, composed chiefly of *Orchids*. The bunches of hardy herbaceous flowers were also conspicuous, Messrs. Pritchard being first, Messrs. Heath second, and Messrs. Niemand third. Bouquets were very numerous, Messrs. Perkins being first for both the ball and bridal arrangement with exquisite productions, and Messrs. Jones & Sons, Shrewsbury, and Messrs. Niemand followed in both cases. In the amateur section for the same kind of bouquets Mr. Blair won two firsts with grand specimens composed chiefly of *Orchids*, and Mr. G. Townsend was second. The stands of cut flowers for the table were fair, and the buttonhole flowers not striking. The stands and baskets of wild flowers occupied much space, were highly attractive, the principal prizewinners being Miss Hudson, Miss Kittermaster, Miss Beaman, and Miss Myers.

FRUIT.—Grapes were not so numerous as last year, but many of the specimens were up to the average of former years. The opening class in fruit reads thus:—"Six bunches of black Grapes, two bunches of three varieties. First prize, £10; second ditto, £6; third ditto, £3." Truly a tempting paragraph and one likely to bring some good fruit, which it did. Mr. J. Stevenson, gardener to Col. Pilkington, Prescott, being first with Black Hamburg, grandly finished; Madresfield Court, ripe and well formed, and Alicante, of fine colour, rather small in berry. Mr. Pratt, Longleat, was second with Alicante large, Gros Maroc very good, and Black Hamburg of fine proportions but slightly deficient in

colour. Third, Mr. Dawes, gardener to the Hon. Mrs. Ingram, Temple Newsum, Leeds, with Black Hamburg, Madresfield Court, and Muscat Hamburg in fine condition. In the class for three bunches of Black Hamburgs Mr. Stevenson was first with grandly finished bunches, the colour being perfect. Mr. Brownhill, Rockferry, came second with large berries, but slightly deficient in finish; and Mr. G. Raynes, Rockferry, third. Some fine fruit was shown in the class for any other black Grape, and the Hon. Charles Wynn, Rhug, Merionethshire, was first with Alnwick Seedling, fine in cluster, dense and perfect in colour, but slightly small in berry. Second, Mr. Raynes with Madresfield Court, too brown. Third, Mr. Stevenson with the same variety, fine in bunch.

Mr. Pratt was first for four bunches of white Grapes with Foster's Seedling and Muscat of Alexandria, the latter being the best in the Show. Mr. Stevenson came second with the same varieties not so ripe, and Mr. G. Raynes third. Mr. Pratt was also first for three bunches of white Grapes with Muscat of Alexandria, large in bunch, fine in berry, and grandly coloured; Mr. R. Pilkington came second and Mr. Brownhill third. In the class for three bunches of any other white Grape the Hon. Charles Wynn was an easy first with three superb bunches of Duke of Buccleuch, and Mrs. Marly, Baschurch, second with Buckland Sweetwater. In the class for four bunches of black Grapes open to the county of Salop, Mr. Beattie, Wellington, was first with Black Hamburg, good, and Alicante misnamed Black Tokay. Mr. Lambert second with Black Hamburg and Muscat Hamburg, both good. Third, Mr. Milner, small berries, fine colour. In the corresponding class for white Grapes Mr. Lambert was first and Mr. Milner second. Grapes were well shown in the amateur classes by Mr. Humphreys, Shrewsbury; Mr. Hale, Birkenhead; Mr. Burr, Oaklands; and Mr. Barker. On one stand a poor sample of Buckland Sweetwater was named "Dukeabaelach."

Collection of fruit, twelve dishes, to include two black and two white Grapes, two bunches of each, one Melon and one Pine Apple, first prize, £10; second, £6; third, £3. There was keen competition here, many well known growers exhibiting, but the old hands were rather out of it, as the first prize was well won by Mr. Dawes of Temple Newsum, who staged splendid samples of the following—Black Hamburg, Muscat of Alexandria, Foster's Seedling, and Gros Guillaume Grapes, the latter weighing about 9 lbs. per bunch, with huge berries, well coloured and finely finished; Rivers' Orange Nectarine, Royal George Peach, seedling Melon, Queen Pine, Brown Turkey Fig, James Veitch Strawberry, Roman Apricot, and Late Duke Cherry—a fine collection. Mr. Goodacre, gardener to the Earl of Harrington, Elvaston, Derby, was second with a weighty collection, in which Muscat Hamburg and Foster's Seedling were hardly up in colour, but Muscat of Alexandria fine; a grand Queen Pine, splendid Circassian Cherries, and good Elruge Nectarines. Mr. Pratt was third with good Grapes, but two bunches were badly matched, one being double the weight of the other. Mr. Gilman, gardener to the Earl of Shrewsbury, Ingestrie, was fourth, his Barrington Peaches being remarkably fine. In the collection of nine dishes of fruit, confined to Salop, Mr. Lambert was first with capital Muscat of Alexandria and Black Hamburg Grapes, Apricots, Royal George Peach, large Gooseberries, Early Golden Drop Plum, and Humboldt Nectarine. Mr. Beattie second, and Mr. Milner third. In Peaches Mr. Gilman had no difficulty in securing first prize with splendid Barringtons. Another dish still larger than these but poorly coloured did not gain a prize. Pine Apple Nectarine was first, Lord Napier second, and Pine Apple third. Plums and Apricots were few. Melons came out in goodly numbers. For the best green-fleshed variety Mr. Goodacre was first, Mr. Owen second, and Mr. Pratt third, all unnamed. In scarlet-flesh Blenheim Orange secured the leading prizes. Messrs. Sutton & Sons, Reading, offered prizes for their well known Melons, and these were secured by Mr. Waite, gardener to Col. Talbot, Glenhurst, Surrey; Mr. Barlass, Derby; and Mr. Owen.

VEGETABLES.—Unusual interest was attached to this section, as a Veitch Memorial medal and prize of £5 was offered for the best collection of twelve sorts. This, we believe, is the first time it has been given for vegetables; it could not be offered in a better place than Shrewsbury, and the competition was exceedingly keen and highly creditable. Fourteen collections were staged, and after much careful inspection the Judges awarded the coveted medal to Mr. Lambert of Onslow. This collection was beautifully staged, and the produce was excellent. It consisted of Webb's Banbury Onion, Veitch's Prodigy Pea, Laxton's Czar Runner Bean, Lyon Leek, Intermediate Carrot, Globe Artichoke, Veitch's Autumn Cauliflower, Telegraph Cucumber, Prime Minister Potato, Snowball Turnip, Clarke's red Celery, and Webb's Sensation Tomato. Every dish would have taken a prize in the single classes, and it is a collection of this kind that always tells. Mr. Waite was second; and Mr. Wilkins, gardener to Lady Blandford, third. The next collection was confined to Salop, and here Mr. Lambert was again first; Mr. Corefield, Scaton Knowls, second; and Mr. Farrant third. Potatoes were extensively staged, Mr. Lambert being first for six dishes with Prime Minister, Edgecote Purple, Ashtop Fluke, Sutton's Seedling, Cardmant, and Chancellor, large, even, and clean. Mr. Waite was second, and Mr. Barrington third. Tomatoes, Peas, Cauliflowers, Beans, Onions, Carrots, Celery, &c., were exhibited in great numbers, and the principal prizetakers were Mr. Lambert, Mr. Waite, Mr. Milner, Mr. Cook, Cheltenham; Mr. Davies, Cruckton Hall; Mr. Wilkins, Mr. Lowe, Shrewsbury; Rev. H. Arkwright, and Mr. Barr.

Amongst special prizes the handsome sums offered by Messrs. Webb and Sons, Wordsley, Stourbridge, brought almost as fine a competition as for the Veitch prizes, twelve collections of eight dishes being staged. Mr. Waite secured the first place with finely grown specimens of White

Tripoli Onion, Veitch's Autumn Cauliflower, Intermediate Carrot, Webb's Sensation Tomato, Duke of Albany Pea, Ne Plus Ultra Runner Bean, Clarke's red Celery, and Stourbridge Glory Potato. Second, Mr. Lambert; third, Mr. Skinner, Cheltenham; fourth, Mr. Corfield; fifth, Mr. Wilkins; and several other highly meritorious collections had to be left out. Messrs. Sutton's Cucumber prizes were won by Mr. Skinner, Lord Berwick, Mr. Dick, and Mr. Wyley, Shrewsbury. Mrs. Williams, Dorset; Mr. Waite, Mr. Edwards, Acton Burnell, and Mr. Skinner were the winners for Perfection Tomato, and Mr. Lambert and Mr. Waite for Sutton's Early Gem Carrot. Mr. Thomas Laxton offered prizes for his new Peas, Czar Runner Beans, and Potatoes, and some fine produce was staged by Mr. Lambert, Mr. Milner, and one or two others. The cottagers had a spacious tent all to themselves. The tables overflowed, and the produce in all classes was excellent. This is a department in which some of the surplus funds of the Society might advantageously be spent, as 10s. as a first prize for a collection of eight kinds of vegetables cannot be regarded as handsome or remunerative.

MISCELLANEOUS EXHIBITS.—Local nurserymen, as well as those from a distance, staged many good things, which added considerably to the attractions of the Show. Mr. Murrell of Shrewsbury filled a large table with Tuberosus Begonias. There were several boxes of excellent cut Roses in the centre, with the Begonias at the back and wings. They were not shown as single blooms, but fine plants profusely bloomed, the varieties good, and Maidenhair Ferns were mingled with them in such a way as to hide all the pots. This was a splendid table. Messrs. Cannell and Sons, Swanley, Kent, exhibited a grand group of cut Begonias. The double forms of these were almost as large as Hollyhock flowers, and were the finest ever seen in Shrewsbury. Their single and Cactus Dahlias and double and single Pelargonium flowers were also admirable. Messrs. Richard Smith & Co., Worcester, staged large quantities of plants and cut Roses and herbaceous flowers. Messrs. Clibran & Son, Altrincham, were also large and meritorious exhibitors in these classes. Messrs. Laing, Forest Hill, had a grand collection of Begonia flowers. Messrs. Kelway, Langport, eclipsed all with their Gladiolus, which were wonderfully good, and Messrs. Dicksons & Co., Limited, staged many grand plants and cut flowers, amongst the latter being several fine bunches of Mrs. Reynolds Hole Carnation. Messrs. Jones, Shrewsbury, and Messrs. Pritchard kept up their reputation in this section, as did also Mr. Myers; and Messrs. Dobbie & Co., Rothesay, N.B., had a stand of their specialties, on which Leeks, Turnips, Parsley, Marigolds, and Pansies and Violas were highly attractive. Messrs. Webb & Sons displayed samples of their leading vegetables, Banbury and other Onions, Leeks, and Emperor Cabbage, hosts of Peas and numerous Lettuces being excellent, and the dish of Sensation Tomato was the finest in the Show.

NEWCASTLE-ON-TYNE.

THE Durham, Northumberland, and Newcastle-on-Tyne Botanical and Horticultural Society held their sixty-fifth Exhibition on Wednesday, Thursday, and Friday last in the Leazes Park, Newcastle. It seems almost impossible for the Society to be fortunate enough to secure good weather. The Show this season was about a month later, still with no better success. This is really a pity, as last year the Society was able to hold their show in the grounds of the Newcastle Exhibition, which took them out of debt, and secured a balance in hand of about £300. The present Exhibition, occurring in such extremely bad weather, will be the cause of putting the Society into debt again to the extent of about £50. As regards the merits of the Exhibition it is almost impossible to be too laudatory concerning the stove and greenhouse plants, which were magnificent examples of culture. The fruit was exceptionally fine in all classes. The florist flowers, especially Roses, were well represented, Dahlias and Gladiolus being not so numerous, owing, no doubt, to the extraordinary season. Appended is a record of the successful exhibitors.

In division A, which is open to all, for eight plants in bloom, dissimilar, Mr. E. H. Letts, gardener to the Earl of Zetland, Upleatham, was first with eight superb plants of finished culture; these included Erica Jacksoni, 5 to 6 feet through; E. ferruginea Bothwelliana and E. Marnockiana, all equally good and bright in colour, the plants symmetrically trained, although not too formal or stiff; Phœnocomma prolifera Barnesi, 6 to 7 feet through, of a remarkably deep rich crimson; a fine Lapageria alba, with 200 blooms; Anthurium Schertzerianum, and a grand Allamanda nobilis, completed the eight. Mr. H. Johnson, gardener to J. B. Hodgkin, Esq., Elmridge, Darlington, was second with creditable examples of Ixora Dixiana and I. Williamsi, Erica tricolor Wilsoni, E. Eweriana superba, and Allamanda Schottii, very good. Mr. E. Adams, Swallow, was third, his best plant being a good specimen of Phœnocomma prolifera Barnesi.

In the corresponding class, B, Mr. A. Methven, gardener to T. Lange, Esq., Heathfield House, Low Fell, Gateshead, was first with an Erica Exquisite, 6 feet through, profusely flowered; Stephanotis floribunda, Allamanda Hendersoni, Anthurium Schertzerianum, and Erica æmula. Mr. E. Adams was second with Phœnocomma prolifera Barnesi, Statice profusa, and Erica Aitonia superba. For eight foliage plants Mr. E. H. Letts was again first with noble examples, his Cycas circinalis, C. revoluta, Encephalartos Altesteni, Dion edule, and Kentia Fosteriana towered majestically over the Gleichenia rupestris glaucescens, with Crotons Johannis and angustifolius; the two latter as regards colour were as good as the most fastidious admirers of Crotons could desire. Mr. J. McIntyre, Woodside, Darlington, was second with good plants, showing a handsome Croton, Cycas revoluta, C. circinalis, and Cordyline indivisa. Mr. A. Methven was here third, his best plant was a good Croton Weismanni,

and in the corresponding class, B, he was first for six foliage plants, including Kentia Fosteriana, Cycas revoluta, an Encephalartos, Croton Mortii, and Cordyline indivisa. For six exotic Ferns Mr. H. Johnson was first, Davallia Mooreana, truly grand, 8 feet; Dicksonia antarctica, Microlepia hirta cristata, Davallia fijiensis, and Gleichenia Mendellii. Mr. McIntyre in this class was second, and a good first in the corresponding class for six, including Pteris Cowani, Adiantum decorum, and A. cuneatum. For four Ericas Mr. E. H. Letts followed up his usual success, and seldom, if ever, have Ericas been shown better; these included Erica tricolor Wilsoni and E. Turnbulli. Mr. Johnson was second and first in the B class for three Ericas, including E. æmula, E. McNabiana and E. ferruginea superba.

TABLE DECORATIONS, CUT FLOWERS.—Dessert table, 10 feet by 5 feet 4. This only brought two competitors. Mr. O. Lamb, gardener to C. E. Hunter, Esq., South Hill, was first with a very fine table, on which was one centrepiece, two end pieces, four semicircular glasses, eight small or thumb glasses, and eight dishes of fruit. The glasses were of the newest pattern, a *fac-simile* set of which has been supplied to Her Majesty recently. The centre was most effectively filled with Francoa ramosa, Water Lilies, Dipladenia boliviensis, Ixoras, Anthurium Andraeanum, and other choice flowers, all lightly and harmoniously blended together. Mr. F. Gillender, florist, Grey Street, was second; his centre contained very choice flowers, but much too heavy. For a vase or epergne Mrs. E. Adams was first amongst five competitors, Mr. F. Edmondson, Green Market, Newcastle, second, and Mr. Rutherford, Leazes, Durham, third, all good. For the basket of cut flowers there was a good competition, Messrs. Perkins & Sons, Coventry, being first, in which Odontoglossum Alexandræ figured conspicuously, and the handle was draped with Lygodium scandens; Mr. J. R. Chard was second. For the bridal bouquet Messrs. Perkins were again first. Caladium argyrites was employed with much effect, and amongst the flowers were Stephanotis, Tuberoses, Niphetos Roses, and Eucharis Mastersi, which seems quite an acquisition. For a hand bouquet the former winner was also first; Dipladenia Brearleyana, Oneidium flexuosum, Eucharis, and white Lapagerias were employed with Francoa ramosa. Mr. J. R. Chard was second with good bouquet of Cattleya Mossiæ. For the ladies' spray, a new idea at Newcastle, Messrs. Perkins were also again first with a most charming combination of Oncidium flexuosum, Epidendrum vitellinum, Odontoglossum Alexandræ, and Caladium argyrites. Mr. J. R. Chard second. Buttonholes always form a strong class, Mr. Geo. Corbett winning with a tasteful arrangement of Hoya bella, Forget-me-nots, Bouvardias, Tuberoses, with Adiantum gracillimum. Mr. J. R. Chard was second with Epidendrum vitellinum, Odontoglossum Alexandræ, &c. In the corresponding class, B, Mr. Jos. Puntun was first for an epergne; for a basket of cut flowers Mr. Geo. Corbett; and for a bridal bouquet Mr. F. Edmondson, the latter consisting of Liliun Harrisii, Francoa ramosa, Niphetos Roses, Gardenias, Tuberoses, all fringed with Adiantum gracillimum. Mr. Geo. Webster was second; and for a hand bouquet Mr. T. Battensby was first.

CUT FLOWERS.—With twenty-four Dahlias, dissimilar, fancies excluded, there were five competitors, Messrs. Henry Clark & Son, Rodley, Leeds, being first with exceptionally good blooms for the season, fine in form, of good colour, and outline well defined; these included J. Henshaw, James Cocker, J. T. West, Earl Ravensworth, Prof. Gooday, Vice-President, Wm. Rawlinson, J. N. Keynes, Goldfinder, Antagonist, and two or three promising seedlings. Mr. N. Walker, Low Fell, Gateshead, was second with smaller flowers. The season has evidently told against this well-known north country exhibitor. There were four collections of twenty-fours. For twelve fancies, Messrs. H. Clark were again first for twelve fancies, including J. Forbes (splendid), W. Saunders, A. T. Barron, General Gordon, and J. B. Camm. Mr. C. Hockey was second. Mr. Thos. S. Ware, Hale Farm Nurseries, Tottenham, London, offered £5 for the best collection of Cactus Dahlias, which brought forth no competition.

For twenty-four Hollyhocks the Society offered £10 in four prizes of £4, £3, £2, and £1, and the Royal Horticultural Society's bronze medal for first. Messrs. Webb & Brand, Saffron Walden, were first, including flowers of Crimson Queen, Queen of Yellow, Joy, Purple Queen, Constance, Alfred Charles, nobilis, Prince Arthur, Golden Drop, Fire King, and two or three seedlings. Mr. Richard Mann, Howden Dyke, was second; and in the class B, for twelve flowers, Mr. R. Mann was first with Purple Prince, Lady Winn, Excelsior, Scarlet Gem, Princess Louise, John Kaye, and also second. For eighteen spikes of Gladioli Messrs. Harkness & Sons, Bedale, were first, including Shakespeare, Valtevarado, Dahlia Dido, and several seedlings. Messrs. Mack & Son were second. For twenty-four Roses, not less than twelve varieties, Messrs. Harkness and Sons were deservedly first; for richness of colour and substance the blooms were much admired, and most deservedly. Their best flowers were Etienne Levet (splendid), Lady Hoffir, A. K. Williams, Catherine Mermet, Lady Fitzwilliam, Devonensis, Paul Neiron, &c. Messrs. Perkins & Son were second with Maréchal Niel, good for the season; Alfred Colomb, A. K. Williams, and Louis Van Houtte.

For eighteen bunches of herbaceous flowers, Mr. T. Short, gardener to Arthur Pease, Esq., Darlington, was first. These are always shown well at Newcastle. On the stands were Liliun chalcœdonicum, Chrysanthemum maximum, Lythrum roseum superbum, Delphinium M. Barrel, Phlox B. S. Williams, and Alstromeria. Messrs. Harkness & Son were second with Liliun Harrisii, Achillea Parmica, Chrysanthemum maximum, Papaver nudicaule miniatum, Erigeron speciosus, Helianthus miniatus plenus, and Centaurea montana. This was a splendid stand, and by many considered equal to the first, except that the former was

more effectively staged. Mr. J. Battensby was third also with a very good stand. For twelve bunches of cut flowers Mr. Geo. Duncan, gardener to C. H. Wilson, Esq., M.P., was first with *Bougainvillea glabra*, *Vallota purpurea*, *Eucharis grandiflora*, *Clerodendron fallax*, *Calanthe veratrifolia*, *Cattleya crispa*, and *Lapageria rosea*. In the B class, Mr. Duncan was also first for cut flowers. Pansies were shown well, Messrs. Bailey & Sons, Sunderland, being very successful.

FRUIT.—For a collection of twelve dishes of fruit the Society offered £20. Mr. J. McIndoe, gardener to Sir Jos. Pease, Hutton Hall, Guisborough, was first with Gros Maroc and Golden Champion Grapes, a handsome Pine, Galande Peaches, Darwin Nectarines, Plums, Frogmore Cherries, Apriots, large early Ribston Pippin, and Clapp's Favourite Pear. Grapes and Pine Apples were the leading features. Mr. J. Hunter, Lambton Castle Gardens, was second with Black Hamburg and Canon Hall Grapes, Smooth Cayenne Pine, early Grosse Mignonne Peaches, Souvenir du Congrès Pear, white Magnum Bonum Plums, Worcester Pearmain Apples, Melon Ilarefield Grove, Negro Largo Figs, and the fruit of the Sago Palm. For eight dishes these exhibitors reversed their positions, Mr. Hunter showing Canon Hall Grapes, Black Hamburg Grapes, Grosse Mignonne Peaches, and Souvenir du Congrès Pears. Mr. McIndoe was second with Duke of Buccleuch and Black Hamburg Grapes, Golden Eagle Peaches, Williams' Bon Chrétien Pears, Elroge Nectarines, &c. Mr. P. Westcott, Raby, was third, showing good dishes of Black Hamburg, Bowood Muscat Grapes, Spencer Nectarines, Royal George Peaches, &c.

For four dishes, Pines excluded, Mr. Hunter followed up his former success, showing Black Hamburg Grapes, very fine; Marie Louise Pears, Lockinge Hero Melon, and Apples. For six dishes of hardy fruits Mr. J. Short was first and Mr. Westcott second. For six bunches of Grapes, not less than three varieties, Mr. J. Hunter was also first again with fine even finished fruit of Golden Champion, 4 lbs.; Alnwick Seedling, Alicante, and Muscat of Alexandria Grapes. Mr. McIndoe took the second place with Golden Champion, Gros Maroc, and Black Hamburg. For two bunches of black Grapes there were eight competitors, Mr. C. Portsmouth, Rectory, Morpeth, being first. For Black Alicante Grapes Mr. J. Hunter was first and Mr. Witherspoon second. For two bunches of any sort Mr. Witherspoon was also first amongst seven competitors, and the same exhibitor took the first place for Buckland Sweetwater as well. For white Grapes, any sort, Mr. J. Hunter was first with Duke of Buccleuch. Melons were a most extraordinary show, the first prize falling to Mr. F. Clarke amongst nineteen exhibitors. Mr. Wm. Jenkins won the first place for Peaches, Mr. J. Riddell was first for Nectarines, and Mr. R. Westcott first for Apriots. Mr. W. J. Watson and Messrs. Tring, local nurserymen, gave prizes for collections of vegetables. There were five competitors, Mr. Simon Bulmer, Scotswood-on-Tyne, winning with a very fine collection.

NOT FOR COMPETITION.—A stand of Poppies, including *Papaver nudicaule* and alba, and miniatum, was shown by Messrs. Harkness and Sons, and the flowers were much admired for the softness of their colour. The Society awarded a special certificate for them. The same firm also exhibited stands of Roses, and received a special certificate for them. Messrs. Wm. Fell & Co., Hexham, exhibited a special stand of Coniferae, highly coloured and well grown, including such varieties as *Juniperus japonica aurea*, *Cupressus Lawsoniana*, *Thujaopsis borealis compacta*, *Retinospora*, *Thujaopsis plumosa aurea*, and the ever lovely *Chamaecyparis sphaeroides aurea*. Mr. W. R. Armstrong, High Cross, Elswick, exhibited a fine stand of stove and greenhouse plants, including specimen *Lapagerias*, *Crotons*, and *Palms*. Messrs. Little & Ballantyne also had a similar collection. These exhibits compensated for the Society not offering prizes for groups of plants this year. Messrs. Clark Bros., Carlisle, exhibited six stands of Carnations. Messrs. J. Robson, Hexham, showed a good stand of greenhouse and stove plants, and Whinham's Industry Gooseberry, three years old, bearing profusely. Messrs. Kent and Bryden, Darlington, showed an excellent stand of herbaceous plants, including many rare and choice varieties.

After the judging was completed the Committee and Judges lunched in an adjoining tent. The Treasurer, Alderman Grey, was in the chair, supported by the Mayors of the neighbouring boroughs, and Sir Jos. Terry from York. The Judges, in replying to their toast, complimented the staging Committee on the effective way they had discharged duties in rendering every assistance necessary to the Judges, and particularly mentioned Mr. Ed. Wilson's name. In conclusion also a word of praise is due to the exertions of the Secretary, who is indefatigable in his duties. With such officers as he and the respected Treasurer the Society need have no fear for the future, despite the unfavourable weather this year.

RYDE, ISLE OF WIGHT.

MUCH public spirit is displayed in this fashionable yachting town; throughout the season various fêtes are organised and successfully carried out by an energetic body of gentlemen called the Ryde Sports and Amusements Association. It is very gratifying to know that horticulture has a prominent place in the programme. The Rose Show in June, the Show under notice, and the Chrysanthemum Show in November, being all managed and arranged very satisfactorily by the above Association. The Exhibition was held on Thursday, August 23rd, in the beautiful and sloping terrace gardens, by kind permission of Mr. G. Pack. The Exhibition was opened by the Mayor and Corporation, and the gardens were illuminated in the evening. Two marquees were filled with various exhibits, and the cottagers' vegetables were arranged on a long row of tables under the shady Elms.

The chief exhibitors in the plant classes were Mr. Earle, gardener to

Henley Grose Smith, Esq., The Priory, St. Helens, and Mr. Wilkins, gardener to W. S. Ridley, Esq., The Castle, St. Helens; the former taking first in stove and greenhouse flowering plants, and the latter first with ornamental foliage plants. For a group arranged for effect Mr. Earle was again first with an arrangement of Palms and Ferns intermixed with *Oncidiums* and other Orchids. Mr. Wilkins was a close second, with J. O. Brooks, Esq., Fernside, third. Mr. Earle was also first with six exotic Ferns with a fresh collection containing good plants of *Davallia Mooreana*, *Dicksonia antarctica*, &c., Mr. Wilkins following closely with larger plants. Mr. Wilkins took the lead in both classes for table plants, and also in the class for six Coleuses, and his six Cockscombs that won the first prize was one of the features in the Show, being dwarf and fully developed.

The several classes for cut flowers was well contested, the orange shades of the cut Marigolds toning down the gaudy and bright flowers of Zonal Pelargoniums, both of which were very striking features. Mr. G. Barton took the lead with the African, and likewise with the French Marigolds with some fine massive blooms, and Mr. J. Attrill, Mr. G. Pack, Mr. H. Quinton, and J. O. Brook, Esq., took the prizes for the cut Pelargoniums. The cut Zinnias was the best we have seen for a long time, the prizes being awarded to Messrs. Blake, Barnes, and Attrill. There were also good competition for six distinct varieties of annuals in bunches, and Dahlias, Asters, Phlox, *Gladiolus* were all more or less represented by good stands of blooms.

The best bouquet in the Show was one not for competition sent by Messrs. W. & G. Drover, Farcham, consisting of Gardenias, Stephanotis, Tea Roses, and other choice white flowers; this was presented in the evening to the Mayoress. The best competing one was from Mr. J. Banting, Shanklin, who was also first for three beautifully arranged ladies' sprays. For six buttonholes Mr. Attrill was first and Mr. Earle second. Mr. Attrill was also first for a wreath of white flowers, Mr. Jeffrey second, and Mr. Dunning third. The gipsy baskets filled with flowers had a very pretty effect, Miss Brook being first with an elegant arrangement, Mr. Quinton second, with Mrs. Morris third. In competition for a design for a summer screen for a fire stove, to be composed of everlasting or dried flowers and grasses, some very effective and elegant arrangements were shown. Mrs. E. Brook, High Street, and Miss Brook taking the prizes with most artistic arrangements. Special prizes were offered by Professor Simmonds, the Chairman, for the best floral representation of the Union Jack, in a tray 36 inches by 25 inches. There were four entries, making a very gay effect and causing quite an excitement amongst the company, and ultimately proved a very ticklish thing for the Judges to deal with, the one first selected by them being technically wrong in the width of the white stripes, and their decision had ultimately to be reversed, Miss Nutt taking the first, Mr. G. H. Kent the second, and Mr. F. C. Price the third. The subjects employed in the several exhibits being individual flowers in sand, of scarlet Pelargoniums for the main stripes, white Pelargoniums, white Stocks, and *Achillea Parmica* fl. pl. for the white bordering, with a blue groundwork of the deep coloured Corncockle, the latter being used in all the designs.

With a few exceptions the fruit was only moderate. Mr. Richards, gardener to Mrs. Norton, Bonchurch, taking the prize for the two heaviest bunches of Grapes, and also the first in the other two classes for black and white Grapes; Mr. A. Tolly, St. Helens, and Mr. G. Burden, being the chief exhibitors for Peaches, Nectarines, and other fruits, Mr. C. Martin taking the first prize for a Melon.

Vegetables on the contrary were very good both in the professional and cottagers' classes. Mr. Richards, Bonchurch, was first for a collection; Mr. Charles Orchard, Shanklin; Mr. Pionchon, Shanklin; Mr. Williams and Mr. Lipscomb being the chief prizetakers for the single dishes. International, Snowflake, and Ashleaf Kinleys were represented by good dishes, and Schoolmaster, Village Blacksmith, and Sutton's Seedling were also well shown.—C. O.

BASINGSTOKE.—AUGUST 23RD.

THE twelfth Exhibition of the above Society was held in the "Goldings" on the date named, and was horticulturally a great success. The entries were numerous, while the quality of the exhibits was in most instances quite up to the average. The vegetables are always of high order of merit at this Exhibition. The competition in the leading class—that for twelve varieties—was exceedingly keen, the exhibits being of high quality. Plants and groups were noteworthy features. Amateurs and cottagers produced a capital display. The arrangements worked smoothly under the personal charge of Mr. Weeks, the energetic Secretary.

PLANTS.—The principal class was that for twelve specimens in or out of bloom, which brought four competitors, and produced a capital display. First honours fell to Mr. Bowerman, gardener to C. Hoare, Esq., Hackwood Park, Basingstoke, who staged a freely flowered *Allamanda Hendersoni*, *Ixora Williamsi*, and *Eucharis grandiflora*, with *Cycas revoluta* (fine) and *Croton Queen Victoria*. Mr. F. Mould, Pewsey, Wilts, was second, staging smaller specimens of *Erica retorta major*, *E. Irbyana*, and *E. oblonga purpurea*. Mr. Russell, gardener to W. Bradshaw, Esq., Audleys Wood, was third. For six stove and greenhouse plants in flower three entered, Mr. Mould being first with *Allamanda grandiflora*, *Erica Austiniana*, *E. Irbyana*, and *E. Turnbulli* as his best specimens. Mr. B. Tripp, gardener to Mrs. Field, Goldings, Basingstoke, was second. For the same number of foliage plants Mr. Bowerman was easily first, Mr. B. Tripp being second. For one specimen stove or greenhouse plant in bloom, Mr. T. Weaver, gardener to

W. W. B. Beach, Esq., Oakley Hall, Basingstoke, staged a magnificent one of *Eucharis grandiflora*, bearing fifty-three spikes of bloom. With a very fine *Fuchsia* from 7 feet to 8 feet high, 5 feet wide at the base, freely flowered and loosely trained, Mr. T. Russell was second. The best exotic Ferns came from Mr. Weaver, and healthy specimens they were, of fair size. The best hardy Ferns came from Mr. Kneller, gardener to W. S. Portal, Esq., Malshanger Park, Basingstoke. *Fuchsias* were well staged by Mr. Russell. Mr. T. Best, gardener to C. W. Chute, Esq., had the best table plants, closely followed by Mr. Kneller.

For a miscellaneous group of plants for effect, not to exceed 16 feet the £5 5s. was the leading prize. Mr. Weaver was easily first with a bright yet light arrangement of suitable well-grown plants. Second, Mr. Dauncey, gardener to T. Beckford, Esq., Buckfield, Basingstoke, with a somewhat heavier arrangement. *Coleus* were well staged by Mr. D. Eckett, gardener to R. Bleneowe, Esq., being freely grown and well coloured.

CUT FLOWERS.—For twelve *Roses* Mr. Dauncey was first, staging neat, small blooms. For twelve *Dahlias*, distinct, Mr. Bowerman was first with even, neat, well formed blooms, and also first for twelve quilled *Asters*, while Mr. Kneller took first honours for twelve bunches of cut flowers, distinct, with a neat, choice lot. The best twelve varieties of hardy herbaceous, Mr. Bowerman was a good first, staging an even stand of good varieties.

FRUIT.—One exhibitor (Mr. Best) had a collection of six dishes, Pines to be excluded. Black *Hamburg Grapes*, Peaches, and Nectarines were his best. For two bunches of Black *Hamburg Grapes* six competed, the best coming from Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, with shapely bunches having good berries and colour. Second, Mr. Bowerman with smaller bunches. Third, Mr. Kneller. For two bunches any other black *Grape* Mr. Kneller staged *Gros Maroc* with very fine berries, medium bunches, only wanting more time to make them perfect. Second, Mr. Osman with *Alicante*. Third, Mr. Bowerman. Mr. Kneller was first with the best two bunches of white *Grapes* other than *Muscats* with *Buckland Sweetwater*. Mr. Osman second. The last named competitor staged the best *Muscats* of *Alexandria* in that class, good shapely bunches, even berries, and colour fair. The best green-flesh *Melon*, *Longleaf Perfection*, was staged by Mr. Kneller, while Mr. Bowerman had the first card for scarlet *Melon* with *Blenheim Orange*, and also the first for a dish of Nectarines, well coloured fruits of *Elruge*, Mr. Dauncey being second. Mr. Russell was first for a dish of Peaches with *Noblesse*, Mr. Dauncey being second.

VEGETABLES.—For a collection of twelve varieties, not more than two kinds of *Potatoes* allowed, there were five entries. After a close inspection the leading position was accorded to Mr. R. Lye, gardener to W. H. Kingsmill, Esq., who staged *Reading Perfection Tomatoes*, *Duke of Albany Pea*, *Rousham Park Onion*, *Sutton's White Gem Snowball Turnips*, *Prime Minister Potato*, *Ne Plus Ultra Bean*, and *Autumn Giant Cauliflowers* as his most noteworthy dishes. Mr. Kneller was an exceedingly close second, losing only by one point. *Tomatoes Reading Perfection*, *Matchless Marrowfat Peas*, and *Snowdrop Potato* were his best. Third, Mr. Bowerman. Mr. Kneller took the leading prize for six varieties, the prize being given by Messrs. Webb & Sons, *Rousham Park Onion* being especially fine. Mr. Lye was second. The same competitors held the same positions for six varieties, the prizes given by Messrs. Sutton & Sons, with good quality produce. Mr. Kneller followed up his previous successes by taking first honours for spring-sown *Onions* and for best brace of *Cucumbers*, both good. For a collection of nine distinct varieties of *Potatoes*, nine tubers of each, Mr. F. W. Geers, gardener to Captain Oldfield, was first with large even clean tubers of leading kinds. Mr. Dauncey second.

Messrs. Sutton & Sons were awarded a certificate of merit for a new netted *Gloxinia*, very attractive in appearance, bearing large erect blooms. This firm also staged an extensive collection of hardy herbaceous flowers and annuals.

SALISBURY.—AUGUST 23RD.

FORTUNATE indeed are those managers of horticultural societies who during a season so unpropitious as the present one are favoured with fine weather for their annual show. It seemed at one time that the Show held in the Bishop's Palace grounds on the above date was doomed to be a failure, as the morning broke with a leaden sky and heavy rain, but the weather steadily improved, the afternoon being fine. The attendance was large, and the Show a pronounced success in every way. The high quality of the exhibits throughout showed a decided advance upon those staged at any previous show held in the famous cathedral city, even in the palmy days of "the old society," from the ruins of which the present one has been so rapidly built up, thanks to the untiring efforts of Mr. W. H. Williams, the Honorary Secretary, and the excellent Committee who assist him.

In the principal class £15, £10, and £5 were offered for twelve stove and greenhouse plants, six foliage, and six flowering. Three well-known exhibitors competed for these prizes. Mr. G. Lock, gardener to W. B. Cleave, Esq., Crediton, was a good first, his flowering plants being large, fresh, and densely flowered, and the foliage ones of great size and rich colour; the most noteworthy among them being *Erica Eweriana*, a magnificent plant from 4 to 5 feet over; *Erica æmula*, a perfect mass of flower; *Clerodendron Balfourianum*, large and fresh; and *Bougainvillea glabra* in first-rate condition. Among foliage plants were grand examples of *Eucalyptus villosus amplius*, *Cycas circinalis*, and a tremendous *Latania borbonica*. *Crotons* were represented by grand specimens of *C. Warreni* and *C. Williamsi*, remarkably well coloured.

Mr. J. Cypher, Cheltenham, was second, his plants being smaller throughout, but very fresh and clean. The best specimens were *Bougainvillea glabra* splendidly flowered, *Ixora Fraseri*, *Erica venosa*, and *Clerodendron Balfourianum*. Third, Mr. Wills, gardener to Mrs. Pearce, Basset, Southampton, whose collection contained a well trained and beautifully flowered specimen of *Erica obtata purpurea*. For a group of plants arranged for effect in a semicircular space 12 feet in diameter Mr. Lock again led the way with an arrangement which for elegance, finish, and well-balanced colouring would be hard to surpass. Mr. Wills was second with a bright group, but somewhat formal, and Mr. Wilkins, gardener to Lady Theodore Guest, Henstridge, was third; his groundwork was very well done, but the surface plants scarcely set up enough, and two *Caladiums* in the background would have been better left out. For six stove and greenhouse plants in bloom Mr. Lock was first, showing medium-sized, even plants of *Dipladenia amabilis*, *Erica Farriana*, *Erica Aitoniana*, *Ixora Duffi*, *Allamanda Hendersoni*, and *Phenocoma prolifera Barnesi*. Second, Mr. Williams, *Clerodendron Balfourianum* and *Eucharis grandiflora* being his best plants. Mr. Curry, gardener to Colonel Pepper, Milford Hill, Salisbury, was third. Three good groups of six exotic Ferns were shown, Mr. Wills coming in first with good sized even specimens, Mr. Wilkins being a close second, and Mr. Smith, gardener to the Lord Bishop of Salisbury, third with smaller but remarkably fresh specimens.

For six *Begonias*, distinct, Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, was easily first with well-flowered even plants. Mr. Wilkins second, and Mr. E. Thornton, gardener to Mrs. Greenwood, Harnham Cliff, Salisbury, was third. *Fuchsias* were not shown in large numbers, nor were they of great size. Well-flowered specimens secured for Mr. F. Wills the first prize; *Beautiful*, *Charming*, and *Elegance* were the best in his half dozen. Second, Mr. L. Brown, Portland Place, Salisbury.

Five pounds were offered as the first prize for a group of plants arranged for effect in a semicircle 10 feet in diameter, the competition being confined to gentlemen's gardeners. Seven competed, which made quite a display in themselves, all being exceedingly well done. Mr. Lock was again to the front, winning the £5 cup or money given by Messrs. Keynes Williams & Co., of Salisbury, with a graceful arrangement similar to his first prize group in the open classes. Second, Mr. J. Budd, gardener to F. G. Dalgety, Esq., Lockerley Hall, Romsey; Mr. Wills being third. Another class was provided for a group of plants of the same size and shape as the last-named one, but the competition in this case was confined to amateurs within a radius of six miles of Salisbury, the first prize being a cup given by the Mayor of Salisbury, and valued at £5. This was well won by Mr. L. Brown with a light, and in every way beautiful arrangement, the exhibitor having evidently studied the tasteful exhibits in the open classes in previous years. Dr. F. W. Coates was second, his background being very good, but the front too flat; Mr. Lovibond third. For a group of plants arranged for effect, 8 feet in diameter, Mr. Gregory was first, and Mr. Greenwood second. Mr. J. Nightingale, Wilton, was first for six Ferns; Mr. L. Brown, for a like number of *Pelargoniums*. For four *Pelargoniums* with variegated foliage Mr. T. S. Fletcher was successful. The six best *Coleus* came from Mr. G. Smith, Wilton Road, Salisbury; and three very fine pots of *Lilium auratum* won for Mr. Gregory the first prize.

FRUIT.—In many classes this was both numerous and well shown, the black *Grapes* being especially good; the white ones in some cases showed the effect of the unfavourable season by their rather green appearance. For a collection of eight dishes of fruit Mr. Ward was first, showing fine examples of *Madresfield Court Grape*, the bunches being of medium size, berries very large and beautifully coloured; *Muscats of Alexandria*, large bunches fairly well coloured; a well-ripened *Smooth Cayenne Pine*; fine *Scarlet Invincible Melon*, *Pineapple*, *Nectarines*, *Goshawk Peaches*, *Negro Largo Figs*, and rather small *Apricots*. Mr. Evans, gardener to Lady Louisa Ashburton, Melchet Court, Romsey, was a close second. He had well-coloured Black *Hamburg* and fairly good *Muscats of Alexandria Grapes*, a neat *Queen Pine*, good *William Tillery Melon*, grand *Brunswick Figs*, *Lord Napier Nectarine*, well coloured, but rather small for the variety, *Barrington Peaches*, and *Moor Park Apricots*. Mr. A. Miller, gardener to H. W. Long, Esq., M.P., Rood Ashton Park, Trowbridge, was a good third, his collection containing a grand *Smooth Cayenne Pine* weighing about 7 lbs., but a few of the uppermost pips were rather green. His *Nectarines*, *Figs*, and *Melon* were also very good. Mr. Lock was first for a *Pine Apple* with a fine *Smooth Cayenne*, Mr. Ward being a good second with the same variety, and Mr. Evans third with a *Queen*. *Muscats of Alexandria* was staged by five exhibitors. Mr. T. Northeast, gardener to Mrs. Torrence, South Bavant, Warminster, was first with large bunches, and berries fairly well coloured. Second, Mr. Haines, gardener to the Earl of Radnor, Coleshill House, Highworth, with compact bunches and large berries. Seven lots were put up in the class for three bunches of Black *Hamburg*, the first prize being justly awarded to Mr. Chalk, gardener to G. Read, Esq., Westwood, Salisbury, for splendid examples, being large in bunch and berry, and beautifully coloured. Mr. Ward was second with smaller, but well-coloured bunches; Mr. Inglefield, gardener to Sir John Kelk, Bart., Tedworth House, Marlborough, third. For three bunches for any other white Mr. Ward was a good first with *Buckland Sweetwater* in good condition, Mr. Haines being second with well-coloured *Foster's Seedling*, and Mr. W. Neville, gardener to F. W. Flight, Esq., Twyford, third with the same variety. Mr. Ward was again to the front in the class for three bunches of black,

not Hamburg, showing Gros Maroc, finely coloured; second, Mr. Miller, with Alnwick Seedling. For the best-flavoured Melon Mr. Neville was first with a fine-flavoured fruit of Sutton's Imperial Green Flesh; and Mr. Evans was second with Read's Scarlet Flesh. Five good dishes of Peaches were shown, Mr. Inglefield scoring an easy victory with large, solid, and splendidly coloured fruits of Walburton Admirable; Mr. Budd being second with Barrington. For six Nectarines Mr. W. Browning, gardener to Sir Talbot Baker, Bart., Blandford, was first with Rivers' Orange in perfect condition; Mr. Ward was second with good Pineapple. Mr. Browning was also first for six Apricots, with exceptionally good fruits of Moor Park; Mr. Budd second, and Mr. Miller third; all showing the same variety. Mr. Inglefield was first for twelve Plums; Mr. Browning second, and Mr. Budd third. For six dishes of Apples Mr. Browning was first and Mr. Smith second, the last-named being the only exhibitor of four dishes of Pears, and he was awarded the first prize.

VEGETABLES.—The competition in the vegetable classes was very keen, and the quality excellent. For a collection of twelve kinds, after a close contest, the premier position was awarded to Mr. Wilkins, who had fine samples of Advance Cauliflower, Lyon Leek, Standard Bearer Celery, Rousham Park Onions, New Intermediate Carrot, Giant White Beans, and dark red Beet. Mr. Haines was a very close second, showing splendid Reading Perfection Tomatoes, Satisfaction Potato, Anglo-Spanish Onions, Giant White Cauliflower, Jubilee Beans, and Major Clark's Red Celery, as his best dishes. Mr. W. Pope, gardener to the Earl of Carnarvon, Highclere Castle, Newbury, was third.

CUT FLOWERS.—Roses were not numerous. Those put up by Mr. Campbell, gardener to Dr. S. P. Budd, Bath, were bright and fresh, though not large. For twenty-four singles trusses, distinct, the above-named was the only exhibitor, and was deservedly awarded the first prize, his best being Louis Van Houtte, Prince Arthur, and Alfred Colomb. For twelve single trusses Dr. D. Seaton, Bitterne, Hants, came in first, having among others good blooms of Captain Christy and Victor Verdier. Mr. Neville was second, and Mr. F. Hatch, Salisbury, was third. For twelve bunches of single Dahlias Messrs. Haskins and Smith secured the prizes in the order named. In the class for twelve Pompons Mr. Haskins, Salisbury, was first, Mr. Hatch was second, the third prize going to Mr. R. West, gardener to J. R. Wigram, Esq., Northlands, Salisbury. Messrs. Campbell, Hatch, and West received the prizes for twenty-four Asters in the order named. For eighteen bunches of cut flowers, distinct, Mr. Evans was first with a collection well set up, containing good spikes of *Cattleya crispa*, *Saccolabium Blumei majus*, and *Strelitzia Regina*. Mr. Budd was a close second, *Calanthe veratrifolia*, *Cattleya crispa*, and *Thunia alba* being his best blooms; third, Mr. Neville. For twelve bunches Mr. Browning was first and Mr. West was second. For eighteen Carnations or Picotees, not less than nine varieties, Mr. M. Gilbert of Bishop's Waltham was a good first; Mr. T. Hatch was second, and Mr. E. Brown third. The winner of the first prize in this class also exhibited fine blooms of a striped border Carnation named Edwin Molyneux, and as the variety bids fair to be worthy of the name, it fully deserved the certificate of merit which was awarded to it. Mr. Chard, Stoke Newington, was first for a flower vase with one of his best efforts; Miss Bessie Flight was second, and Mr. J. Cypher was third. For two bouquets, one bride's and one ballroom, Mr. Chard was again first, and Mrs. Field, Salisbury, second.

Among the exhibits not for competition Messrs. Keynes, Williams, and Co. had good groups of fine-foliaged plants and Lilies and a large collection of Dahlias and Roses, which made quite a show in themselves, and contained many examples of the highest order of merit, several promising seedlings being also shown. The same firm exhibited an exceedingly well made ballroom bouquet, which was much admired.

First-class certificates were awarded to Messrs. Keynes, Williams, and Co. for Cactus Dahlias "Panthea," light terra-cotta, and "Amphion," a very large showy terra-cotta coloured flower. A plant of *Cattleya Dowiana* carrying a good spike was exhibited by R. Blake, Esq., of Winterbourne, and was awarded a certificate of merit. Mr. B. R. Davis of the Yeovil Nurseries had a very fine assortment of Begonias, the most noteworthy among the doubles being *Altheaeflora*, a bright rosy cerise flower very full. Ella L. Davis is also a very fine white, and I noticed another white not yet named. Mannette and Picotee are promising flowers of a new type. The single varieties exhibited were extremely bright in colour and of large size, the very best types only being selected for seed. A collection of cut herbaceous flowers and dwarf and profusely flowered double flowered seedling Petunias put up, also not for competition, by Mr. B. Ladhams, High Street, Shirley, Southampton, also attracted a good deal of attention from visitors.

On reading a report in a local paper of the Wilts Show on the day after the Exhibition I was extremely sorry to learn that one of the exhibitors had assisted to judge in a class in which he was himself an exhibitor.

Although it is sometimes expedient to appoint exhibitors to assist in judging, yet I have never before known an instance of this kind, where the exhibitor felt himself so pure-minded, unselfish, and impartial as to be able to fairly judge his own productions in competition with others. The usual practice is for the judge in such a case to excuse himself to the other judges, gracefully retire, and allow them to award the prizes to the best of their ability without his assistance. I need scarcely say, had I known he was an exhibitor (and I feel sure I may also say the same of my other colleague), I should have declined to act, and so render myself liable to the censure, which we all apparently so richly deserved, and which we, no doubt, fully received from the

other exhibitors, and those who knew the facts of the case. It is needless now to discuss the question whether, under other circumstances, the decisions would have been given differently; my chief object is to exonerate myself and my other colleague from blame, and I feel certain I may also venture to say the committee, who could not have even supposed that anyone would have been so foolish as to think such an act would be either overlooked or excused.—T. CHALLIS.

DEVON AND EXETER.

THE most successful Exhibition, from a financial point of view, this Society has had for many years was held at Northernhay Park, Exeter, the weather for once being very favourable. As a consequence the tents were crowded almost from the opening hour with a fashionable company, still greater crowds thronging the Exhibition grounds in the evening. The exhibits were not removed from the tents before 10 P.M. This, though very pleasing to the visitors, who were enabled to have a view of the plants, flowers, fruit, and vegetables with the aid of illuminations, was far from satisfactory to the exhibitors, most of whom were unprepared for this unexpected decision of the Committee. On the whole the competition was not so keen as usual, but in spite of this a very good show was arranged. Mr. G. D. Cann is the Honorary Secretary, and with him are associated a good working Committee.

In the plant classes Mr. G. Lock, gardener to W. B. Cleave, Esq., Crediton, was the most successful exhibitor, among the specimens shown by him being many that have been previously noticed in the reports of the shows held at Weston-super-Mare and Taunton. His Palms and Crotons were especially fine, and he had several well-flowered specimens of *Ixoras*, *Ericas*, *Allamandas*, and *Bougainvilleas*. Mr. Rowland, gardener to W. Brock, Esq., succeeded in winning the silver cup for nine flowering plants, among these being good sized well-flowered specimens of *Allamanda Hendersoni*, *Ixora Williamsi*, *Stephanotis floribunda*, *Dipladenia amabilis*, *Bougainvillea glabra*, *Anthurium Andreanum*, and *Rondeletia speciosa*. Mr. Lock was a good second, his plants, however, not being quite fresh enough. The best six flowering plants were staged by Mr. E. Mollon, gardener to Mrs. Pouget, the same exhibitor being also first for British Ferns. Classes were also provided for Orchids, Fuchsias, Gloxinias, Liliiums, Begonias, Zonal Pelargoniums, Lycopodiums, and Ferns, in all of which the competition was fairly good. Groups arranged for effect, and occupying 100 square feet, are always a feature at the Exeter Shows, Messrs. Lock and Rowland being the most successful exhibitors. This year Mr. Lock was well first with a light, bright, and very pleasing arrangement, in which elegant Palms, well coloured Crotons, and various choice flowering plants were seen to good advantage springing out of a groundwork of Maidenhair Fern. Mr. Rowland, who took the second prize, also had a capital bank of plants, but these were not so tastefully and lightly arranged as were Mr. Lock's.

Cut flowers were numerous and good, the most successful exhibitors being Mr. J. Walter, Exeter, Mr. J. Nation, and Mr. Humphries, Chippenham, the two last named being the principal competitors with Dahlias. Master J. Lock repeated his success with a dinner table completely arranged for dessert with decorations of flowers and fruit, laid for ten persons. The principal feature in the decoration consisted of three central cpergnes most tastefully filled with Grasses, foliage of *Croton Chelsoni*, Ferns, and choice flowers.

The competition with fruit was not so keen as usual. The best collection of ten dishes was staged by Mr. W. Iggulden, gardener to the Earl of Cork, Frome, who had a good Queen Pine, Black Hamburg, and Muscat of Alexandria Grapes, Hero of Lockinge Melon, Sea Eagle Peaches, Lord Napier Nectarine, Florence Cherries, Figs, Plums, and Apricots, all in good condition. Mr. C. Bull, gardener to Sir Redvers Buller, Crediton, was first for six dishes, these consisting of good Black Hamburg Grapes, High Cross Hybrid Melon, Elruze Nectarines, Bellegarde Peaches, Napoleon Bigarreau Cherries, and Denniston's Superb Plum. Mr. Crossman, gardener to J. Brutton, Esq., Yeovil, was second. Mr. Bull gained a first prize for a fine well ripened Smooth Cayenne Pine Apple. Mr. Barnes, gardener to T. C. Daniels, Esq., was first for Muscat of Alexandria; Mr. Iggulden for Foster's Seedling; Mr. J. Langworthy, gardener to G. P. Bouverie, Esq., for Madresfield Court; and the Rev. H. Clark for Buckland Sweetwater, the exhibits being highly creditable in each instance. Mr. Crossman had the best Melon, winning with a good fruit of Hero of Lockinge. A fine highly coloured dish of Sea Eagle Peach, staged by Mr. Iggulden, was awarded first prize, and in the class for Nectarines Mr. Crossman was first with Pine Apple. Hardy fruit generally was well shown, and vegetables as usual were remarkably good. The best twelve dishes of the latter were staged by Mr. R. Mairs, gardener to Sir J. Shelley.

Messrs. Lucombe, Pince & Co., Exeter, contributed a grand lot of stove and greenhouse plants, as well as several good stands of Roses and other cut flowers. Messrs. R. Veitch & Son, Exeter, also arranged a very pretty group of choice flowering and fine-foliaged plants, including several good Orchids, while from Messrs. Kelway & Son, Langport, came capital samples of Gladioli, Gaillardias, and other flowers.

HELIOtropes.—Insert cuttings of these plants in quantity for early spring flowering. Directly they are rooted place the young plants singly in 3-inch pots, and encourage them to make sturdy growth, so that dwarf bushy little plants are produced by the end of the year. The shoots must be pinched from time to time, and the plants grown as sturdily as possible.—W. N.

HARDY FRUIT GARDEN.

STRAWBERRY RUNNERS.—It is not always convenient or possible to form fresh beds in July or early in August, but unless this important work is carried out both timely and thoroughly it had far better be delayed till the following spring. This admits of the ground being well and deeply dug, plenty of manure being mixed with each spit, and if it is done early in the winter, or as soon as cleared of preceding crop, it will have settled down sufficiently for the Strawberries to be planted in April. In anticipation of this, the required number of rooted runners should now be taken from between the rows of old plants, these being bedded out in rows on a border or a good open piece of ground. They may be planted 4 inches asunder in rows 6 inches apart, and beyond being watered when first put out, and once or twice subsequently, and kept clear of runners and weeds, no further trouble need be taken with them till they are wanted next spring. Thus treated, they increase in size, form abundance of roots, and are transplanted readily with a trowel. Plantations formed in the spring ought not to be allowed to fruit the same season; but if the flowers are pinched out as fast as they form grand plants will be secured, which will bear heavily the following season. The ground need not be given up wholly to spring-planted Strawberries, and the spaces between the rows may be profitably utilised for Lettuces, Onions, and other quick-growing vegetables that do not attain a great size.

TREATMENT OF OLD STRAWBERRY BEDS.—There are yet a few cultivators who cling to the old practice of cutting away all the foliage from Strawberry plants soon after the crops are cleared off, this resulting in the formation of fresh foliage and crowns. It is not necessary or advisable to go to this extreme, but at the same time it is preferable to allowing the beds to remain for many weeks in a rough and much crowded state. Directly sufficient runners are obtained for planting or fruiting in pots, all plants that are to be reserved for fruiting next season ought to be trimmed round with the knife, this removing all runners as well as many old leaves. The next proceeding should be to well hoe the ground about the plants, after which all rubbish should be lightly cleared off and burnt. It is unwise to thoroughly clear the ground of all the mulching material with the rubbish, as the former should be left on as much as possible in order to prevent cracking, and also to keep the roots near the surface. The aim ought to be to encourage healthy vigorous growth, this laying the foundation of a good crop of fruit next season. It is very unwise to preserve old or exhausted beds, these rarely producing fruit either of good size or quality. Younger plants produce the earliest and best crops, and a bed ought to be formed every season, and an old one destroyed. At this late date it is not advisable to follow Strawberries with Broccoli, Savoys, or Borecole, though all these succeed surprisingly well when planted earlier on solid rich ground. The first opportunity should be taken of digging the ground deeply and roughly, the action of frosts, winds, and rain thoroughly pulverising it during the winter. Wonderfully heavy crops of Potatoes have been taken from ground thus treated.

GOOD EARLY PLUMS.—As a rule, Early Rivers or Rivers' Early Prolific is principally relied upon to produce the earliest fruit, and it is, though small, a heavy and almost sure bearer. Morocco, a much older variety, does not seem to have retained its hold upon public favour; but it is well worthy a place in every garden where a certain amount of wall space is given up to Plums. Planted in an east or south-east aspect, it rarely fails to ripen a good crop early in August, the fruit being near the size of the Orleans, dark purple in colour, and good alike for dessert or culinary purposes. Dry's Seedling, which was raised about twenty years ago, is as yet not much grown, but is a very profitable variety. It is of vigorous growth, and if not much pruned will bear freely in quite a young state, while well established trees rarely fail to produce heavy crops of very fine fruit, reddish purple in colour, and fit either for dessert or cooking purposes. It usually ripens early in August, but this season the first fruit were gathered in the third week of this month.

FORWARDING PEARS.—The finest of the early varieties are naturally much later than usual, but are fairly plentiful. As neither the Jargonelle nor any of the Williams' Bon Chrétien type will keep many days or even many hours after they are fit to eat, the season should be lengthened as much as possible by artificial means. At the present time (August 20th) luscious fruits of Jargonelle are being sent to the table that were gathered about nine days previous, and while yet in a comparatively hard and green state. Placed in a box of quite sweet hay and set in a warm house or kitchen, the fruit being kept uniformly warm without being exposed to a drying atmosphere, soon ripen and do not shrivel. Only a few, and which appear to be the forwardest, should be gathered at short intervals, and thus treated till such time as those on the trees are fit for use. The Bon Chrétien forms a fairly close succession to the Jargonelle, especially if treated as just advised. The old Windsor and the superior Beurré d'Amanlis may also be forwarded artificially; in fact, the practice is well worthy of being followed in all

cases, always, however, providing the natural season is not unduly anticipated. When gathered long before the seeds commence to change colour, or much before the fruit stalks part freely from the trees, shrivelled, tough and flavourless fruit is the inevitable result. Nothing tainted or of an objectionable odour should come into contact with either ripening Pears or Apples, the latter being especially porous and absorbent, and therefore easily spoilt as regards flavour.

EARLY APPLES.—These also may be forwarded as advised in the case of Pears, but as a rule are much more juicy and pleasantly flavoured when gathered direct from the trees, or when they drop off. Beauty of Bath, Irish Peach, and Quarrenden are all crisp, juicy, and sweet when gathered ripe from the trees, but after being stored a short time lose in quality most surprisingly.

FRUIT FORCING.

FIGS.—Unsatisfactory Cropping.—Trees planted out not unfrequently grow rampantly, and consequently produce thin crops of fruit. In that case root-pruning may be resorted to, and the roots be confined to a border 3 to 4 feet in width. If the drainage be defective it will be necessary to lift the trees in the autumn as soon as the leaves commence falling and replant in fresh soil. Place 9 to 12 inches of rough stones or brickbats for drainage, and over it a covering of rough lime rubbish, using the finer parts for mixing with the compost in the proportion of one part to five of turfy loam, the latter preferably rather strong than light, and a twentieth of crushed steamed bones. In replanting, ram the soil well about the roots, for short-jointed fruitful wood cannot so well be secured by any other means as by a solidified compost. The border need not be more than 24 inches deep, due allowance being made for the compost subsiding. Should the drainage be good it will only be necessary to confine the roots to the narrow border, and removing some of the old soil from amongst them, replacing with fresh material, and top-dressing with the compost before named, but not covering the roots more than 2 or 3 inches deep.

Earliest Fig House.—The trees will now be ripening their wood, and watering may be discontinued, air being admitted liberally. If, however, the second crop is not yet ripened, moderate moisture in the soil will be necessary, with a rather free circulation of warm air to insure high quality in fruit. Trees in pots we prefer to place outside if the wood be ripe, but the season is so exceptional that the cultivator will require to exercise his judgment.

CUCUMBERS.—It is usual to make a sowing early in August for raising plants to place out early in September to yield a supply of fruits by December and onwards through the winter. We prefer to rely on the autumn fruiters for a supply up to or over Christmas, when plants from a sowing made at the beginning of September will be in good bearing, and continue the supply through the winter and spring months. There is no better variety for fruiting all through the year than a true stock of Telegraph. We, however, have about an equal number of plants to Telegraph of Cardiff Castle, which last, in some plants, give fruits quite as long as Telegraph. We apprehend the pollen of Telegraph had by some means been conveyed to the pistillate flowers of Cardiff Castle; anyway we have on plants from Cardiff Castle seed with fruits surpassing Telegraph in size and freedom of production. The plants showing this freak are from last January sowing still in bearing, whilst those for autumn fruiting (the seed being out of the same fruit) are in every respect the characteristic Cardiff Castle.

Push forward the work of clearing out the house intended for the plants the seed of which is about to be sown. Attend to any repairs that may be necessary, paint or thoroughly cleanse the woodwork with soap and water, limewash the walls, adding a little flowers of sulphur, and clear out the old soil and spent manure. If fermenting materials are employed for bottom heat they must now be prepared; stable litter, and Oak or Beech leaves in about equal proportions thrown together, moistened and turned over two or three times answer very well. Tan is a good material, as it retains heat a considerable time. Hot-water pipes in addition to the fermenting materials will be necessary in the bed to maintain the required bottom heat after that of the fermenting materials is spent.

Assist the autumn-fruiting plants to make strong growth, remove all the staminate flowers and tendrils as they appear, being careful neither to overcrop nor overcrowd the plants. Less moisture will now be necessary unless the weather is very bright, but lightly syringe the plants at closing time, not later than 3 P.M., and sprinkle the walls, &c., at 7 to 8 A.M. The night temperature should be maintained at 65°, 70°, to 75° by day artificially, 80° to 85° or 90° from sun heat, ventilating moderately in the early part of the day so as to insure thoroughly solidified growth, and close sufficiently early to run up to 90° or more.

In pits and frames linings of sweetened fermenting materials will be necessary to maintain the plants in a free-bearing state; keep the foliage rather thin, and stop the growths one joint beyond the fruit. Sprinkling the plants should be discontinued, except on sunny afternoons. Admit air early in the day, and close early in the afternoon. With linings and the protection of mats over the lights Cucumbers will be produced for a lengthened period.

PEACHES AND NECTARINES.—Succession Houses.—Those that ripened the fruit in July will have the buds plumped and the wood sufficiently ripened for the removal of the lights. The removal of the roof lights will tend to the preservation of the foliage and counteract the tendency to over-maturity of the buds or their premature development, by affording the trees the benefit of rains and of night dews, the borders getting thoroughly soaked right through to the drainage by the

autumn rains, which we have invariably found to have an invigorating effect on the trees. Trees that ripened their fruit in August should, as soon as the fruit is cleared, have the wood that has carried fruit not being extensions removed, and any wood not required for next year's bearing, or for the extension of the trees or replacing weakly and exhausted parts, also cut away. This will admit of the freer access of light and air, and of the cleansing of the foliage by water, or insecticide if necessary, it being important that the foliage be continued in a healthy state to as late a period as practicable for the perfecting of the buds and the maturity of the wood. Air should be admitted to the fullest possible extent. If, however, any trees are not ripening well, keep the house rather close by day and throw it open at night, which will tend to check the tendency to late growth and induce maturity both of the buds and wood. There must not be any lack of moisture at the roots, giving a good watering if necessary, or trees that are weakly will be assisted in plumping the buds with liquid manure, not, however, in too powerful doses. Trees ripening their fruit will need to have water withheld from it, and besides affording a due supply at the roots moisture must not be entirely withheld from the atmosphere; an occasional damping of available surfaces, especially on fine days, will be necessary for the maintenance of the foliage in health. If the weather be cold and wet a gentle warmth in the pipes, especially by day, so as to admit of a circulation of air, will be necessary for the satisfactory ripening of the fruit. A temperature of 60° to 65° at night will be sufficient, and 70° to 75° by day artificially in order to a steady progress of the fruit in ripening, air being afforded more or less constantly. If the fruit ripens too rapidly, as may be the case if the weather prove very bright, a shading over the roof lights of a single thickness of pilchard net, or a double one of herring net, will break the fierce rays of the sun, and not only retard the ripening but insure the fruit finishing more satisfactorily than when exposed to the direct rays of the sun.

Latest Houses.—The fruit is very backward. Artificial heat will be necessary, affording a night temperature of 60° to 65° and 70° to 75° by day, and 80° to 85° or 90° from sun heat. Admit air freely, increasing it with the advancing temperature from 75°, keeping through the day from sun heat at 80° to 85°, and closing sufficiently early to continue the temperature at a good heat until late in the afternoon, when a little air should be admitted to allow the pent-up moisture to escape, and no more heat need be in the hot water than necessary to prevent the temperature falling below 60° to 65°. Watering at the roots must only be moderate, though sufficient to maintain the foliage in a healthy state. The growth is unusually vigorous, and gross wood is likely to be made until a late period. Syringe only to keep the foliage clean, and always so as to have the trees dry, or nearly so, before night. Damping at closing time will in most cases be sufficient, and will permit evaporation to continue, insuring the elaboration and assimilation of the sap, and the increased solidification of the wood. Laterals must be stopped, as that is preferable to removing many shoots, which is prolific of gumming, causing other and soft growths to be made.

Unheated Houses.—Keep the inside borders duly watered, but avoid anything like a superabundance of either water or liquid manure, and syringe no more than is necessary to keep the foliage clean. Cut out any gross growths so as to equalise the flow of the sap, having the growths sufficiently thin to admit the full action of light and air. Keep the fruit exposed with its apex to the light. Leave a little air on at night, and by moderate and judicious early opening and early closing of the ventilators secure to the trees as much of the solar heat as is safe, 80° to 85° not being too much.

PLANT HOUSES.

Greenhouse Rhododendrons.—Considerable care is needed to prevent those that have completed their growth starting again. They are much more liable to do this than either Azaleas or Camellias. Harden them thoroughly by free ventilation, and then stand them outside on a moist base in a position where they can be lifted inside if damp wet weather ensues. Although they enjoy abundance of water at their roots they cannot endure being saturated either from the water pot or by heavy rains.

Lapagerias.—Some are beginning to flower; fumigate them with tobacco smoke if aphides exist upon them, or they will soon become established on the flowers and spoil their colour. Water freely and give stimulants in a weak state every other time they need water. Still continue to shade them from the sun, for full exposure will seriously brown and injure their foliage. Light is necessary to harden and ripen their wood if they are to flower profusely, but to accomplish this it is not necessary to subject the plants to the burning rays of the sun.

Fancy Pelargoniums.—Those cut back some time ago will now have broken well into growth. They should have the whole of the soil shaken from the roots, and repotted in fresh, using smaller pots. Keep them close for ten days or a fortnight in cold frames until root action has commenced. Those that are just breaking may be pushed forward by placing them in frames until they are ready for repotting. These plants should be potted moderately firm in a compost of good loam, one-seventh of decayed manure, and a liberal quantity of sand.

Zonal Pelargoniums.—The past wet weather has caused those outside to grow too soft to insure their flowering well unless bright weather follows for the next month or six weeks. Do not administer stimulants, but keep them on the dry side to harden and ripen them as much as

possible. Those intended for flowering in October would be better under glass where they can be protected from heavy rains and dews that are so prevalent in some localities. Insert good quantities of cuttings of both single and double varieties for flowering early in the year; in fact, the latter that are required to supply good trusses for cutting during April, May and June should be rooted at once. Insert these singly in 3-inch pots, and stand them outside until they are rooted if fine weather continues, if not protect them in frames.

Cyclamens.—If the whole of these have not been placed in their largest pots it should be done without delay. Those twelve months old may be placed into 7-inch, while suitable sizes for the remainder will be 5 and 6-inch pots, according to their size. Where the plants have been grown without shade they will have dwarf sturdy foliage, and every attention must be paid to insure their retaining this character until they cease flowering. Plants that are drawn up weakly do not possess half the beauty they are capable of displaying where the foliage is stout and the flower stems need no support. Cyclamens certainly enjoy light shade, but the difficulty is to apply the exact quantity they require without proving injurious to the plants by causing their foliage to grow weakly and too tall to display the handsome character of these plants. It is next to impossible to apply shade without having the plants in this unsatisfactory condition, therefore it is advisable to grow them through their various stages without it. By this method of culture more attention is needed, for the plants must stand upon some moisture-holding material, and need constant watching during bright weather. When grown without shade, with liberal ventilation and bright sun, moisture is evaporated to such an extent that the foliage soon falls over the rims of the pots. This must be prevented as far as possible by syringing the plants liberally, and damping the stages, &c. Avoid saturating the atmosphere during dull, sunless weather, or the foliage may become blotched and the lower leaves decay. Sow seed for next year's plants.

Petunias.—These may also be rooted and grown for the same purpose. They will thrive well with the treatment given to Heliotropes until the close of the growing season, when they can be kept cooler from the middle of November. Marguerites and Fuchsias may also be rooted in quantity, so that they will be ready for 5-inch pots early in the year.

Hydrangeas.—Young plants produced from the heads of those that failed to flower will now have formed bold plump buds that will be certain to flower early in the year. These may either be transferred now into 5-inch pots or during the winter; if more convenient they can be left until they start into growth. With those that have completed their growth thus early, potting at the present time is advisable. Larger heads will be produced than will be the case if potting is delayed. Place them deeply into the pots so that their buds are only just above the surface of the soil, and stand them in a sunny position outside. Later struck plants need not be potted until the winter. Cuttings may still be rooted from outside plants that are growing in an open sunny position.

Schizanthus.—Sow a little seed in a pan, and place it in a cold frame until the seed has germinated. Grow the plants cool to keep them dwarf, and when large enough place them singly into 3-inch pots.

Richardias.—Plants that rested early and were afterwards planted out will now be pushing with great vigour. These may be lifted, and placed in 6 to 10-inch pots, according to their size. The plants can be lifted with large balls of soil, but this is not necessary so long as all the fibry roots are carefully preserved. Pot them in good loam, one-third of manure, and then stand them in a shady place until they are established in their pots. They must have plenty of water and be liberally syringed—in fact, the foliage should not be allowed to become dry until they are established. By this treatment the plants can be housed, and will commence pushing up their spathes by the time it is necessary to lift the general stock.

THE BEE-KEEPER.

CONDITION OF BEES, AND AT THE HEATHER.

As is my usual custom, a week or more before taking my bees to the Heather I dismantled all, then dressed them as they do at the Heather. There is a twofold advantage in this. It gives us the exact quantity of coverings required, and accustoms the bees to the ultimate appearance of their hives, so that when at the moors they do not lose themselves by entering the wrong hive, as they are sure to do when site and covering are suddenly changed.

My first work after uncovering them was to examine and remove all supers, taking away every piece of fully extended and partly filled comb, which is contrary to the management of some bee-keepers, but I work entirely for quality, and the strength of my

hives gives quantity. After my supers or sections are in place, a board is screwed on the top of the case, which secures, and at the same time ventilates the bees, the mouth-piece is closed and the shutter drawn beneath. The latter is done a day or two previous to removing, as it accustoms the bees to the airway, preventing them on the journey from rushing to the floor and succumbing through attempting to get out, as is commonly the case when not opened until starting.

When secured in this manner all that is necessary to do at starting is to close the doorway, bundle up the coverings, then load upon a lorry and take to the station, where a truck is in waiting for them. The truck holds upwards of fifty of these tidy hives, and the cost of taking them fifty miles by rail is about 6d. each, and the conveyance at the other end half of that, to a distance from the station of about half a mile, when in a short time the bees are at work, and this year, by the precautions used, I only observed one lost bee.

The wild Thyme was abundant, and its fragrance was welcomed a long distance. The weather improved on the same day the bees were removed, and the following one was the best honey gathering day of the whole season, the bees falling heavily before they could reach the alighting board. A piece of felt tacked to it allows many falling short to creep to the hive in safety. With a continuation of the improved weather we have enjoyed for some days since the 8th there will still be an abundant harvest of honey. On the evening of the 12th and throughout the 13th a heavy rain fell, accompanied with a bitter high wind. During the month of July the ice was a quarter of an inch thick, and the Potatoes are completely destroyed. An earthquake was heard, and felt too, and not a humble bee is to be seen.

It is not so very long since a correspondent twitted us that they, the B.B.K.A., would cross the border to teach us bee-keeping, but like the one who said he "showed the Scotch the mysteries of the bee hive," after killing most of the bees of a number of hives it has been a failure. It is quite pleasing to me to see them crossing the border to get more wrinkles, and to fraternise with us and our bees on Scottish heath. Not only are bee-keepers coming north, but many Londoners are taking advantage of recruiting their health on and around the moors of Leadhills, where I saw a quantity of the coveted auriferous metal, and where I hope the bees will gather much of the amber nectar to their masters.

I wonder what the lecturer I heard at a late show would have thought of the stinging propensities of bees had he experienced mine after being set down at the Heather. Although I was treating them kindly and with great courage they were furious, which did not astonish me so much as the same lecturer did when preaching the docility of bees while the manipulator was in full retreat! The numerous crosses have much to answer for in this respect, and perfect docility will never be attained unless some means are taken to have none but true Carniolians. But what is the reason that some of my Carniolians are vicious this year, and that with others they are proving themselves an eccentric race? Simply because they are not pure. Certain dealers in England have been sending out queens said to be Benton's, but who never received a queen from that gentleman. It is to be hoped that this will be stopped by bee-keepers taking the hint, and buying their amiable working bees from a reliable dealer. I know whereof I speak in this matter, having experienced much disappointment by having spurious queens in my possession. I saw the progeny of a queen working on the Heather that was sent me from Austria only some five weeks ago, and its general appearance is very different from the progeny of those I had from vendors in England. The state of my hives before removing them to the Heather presents some singular results. Octagons, two supers filled with comb, 16 lbs. Surplus crossed Syrians, the most a surplus of 10 lbs. from a prime swarm. Crossed Cyprians very heavy, but not in supers; have not been fed for eleven years, and was never touched since October till August. No swarms from them this year.

Carniolians swarmed, but were not excessive. Early swarms were in good order, but those after the longest day have dwindled down to a mere handful. All breeds the same, a striking example of the contracting and stimulating process. Owing to the untoward weather, just what we have warned bee-keepers so long against, this year has given us proof positive and fully demonstrated the absurdity of advising bees to be kept in small 10-standard frames, and the greater folly of reducing them to 6 or so on the beginning of the honey harvest, as if we knew when it will commence; but bee-keepers are gradually losing faith in their would-be teachers, and grapple with facts coming under their own observation. My pure Syrians have made no progress since the early spring, always strong, but always losing, and, owing to the weather, unable to gather surplus, but how they work at the Heather is something grand and requires to be witnessed to be fully appreciated. We wish for a continuance of this weather, which will make the whilom light hives with their teeming multitudes great weights, and which will be duly recorded by—A LANARKSHIRE BEE-KEEPER.

APICULTURAL NOTES.

CHANGING QUEENS IN THE AUTUMN.

"FELIX," in his excellent article advising the removal of the old queen and substituting a young one in her place, omitted saying how it was to be done with the least risk or trouble. May I be allowed to point out that the Hallamshire law enables this to be done with the least trouble and no risk whatever? All one has to do is to see that there is no brood or eggs when he removes the old queen; if there is, then he must put the combs containing it into another hive forty-eight hours afterwards, or any time before next May for what it matters. The young queen can be dropped in at any time of the day or night, and no more notice need be taken of her. In most apiaries there will be some stocks headed with young queens it is not intended to remove; if so, the brood or eggs found can be given to them. The young queens can safely be kept a week or more in a Benton mailing cage in a drawer or cupboard ready.

This law is making headway across the Atlantic, where "time savers" and "risk preventors" are in demand. The editor of the *Canadian Bee Journal* seemed struck with Simmins's system as a "time saver," removing the old queen in the afternoon and dropping the fresh queen in the same night, and talked of giving it a trial. This system, which is Mr. Pond's re-dressed, has been thoroughly tested both by T. Bonner Chambers, Esq., F.L.S., and myself, with the result already published—viz., the fresh queen is unmolested until the seventh day at least. She never begins laying before the eleventh, even if in full lay when introduced; that 40 per cent. are missing before the twentieth day; and that very often, if not always, a daughter of hers takes her place before the twenty-eighth day. If anyone doubts this, let him mark or clip the wing of the queen introduced, and I will guarantee he does not find one-third reigning four weeks after, though all will be found safe (!) on the seventh day. Last autumn I drove the bees from three skeps—two for one man and one for another; captured the old black queens, and about midnight I dropped in from the top of each a young Cyprian queen, daughters of imported mothers, but cross-mated. Hybrid Cyprians duly appeared in each stock, and being a long distance away from my apiary there was no suspicion of there being stray young bees. When spring came one was queenless, and the other two were headed with hybrid drone-laying Cyprian queens. The queenless one was given a Cyprian queen in accordance with the Hallamshire law about the end of May, and the black bees were still very numerous in the middle of July.

In one of my letters I mentioned about a young queen hatching out in my hand—a daughter of the queen introduced, the old queen being safe. Well, this queen has been in the hive ever since till yesterday, and she has shown no faulty signs. These are cases I am sure about. In the case of the three skeps young queens were reared which killed their heavy egg-laying mothers; then, there being no drones about, two failed to mate and the third was lost. In the *British Bee Journal* for July 12th an Irishman is quite jubilant over his success in introducing a queen à la Simmins he obtained of Messrs. Neighbour. On the third day after dropping her in he found and cut out two sealed queen cells; on the eleventh day he found some eggs, but no brood, and neither did he succeed in finding the queen. The eggs might have been deposited by laying workers, though more probably by the queen, as everything is just my experience—first queen cells, second no eggs before the eleventh day. The editor does not point out that it was more of a failure than a success; had she been introduced by the Hallamshire law there would have been a lot of sealed brood by that time.

THE GLASS SECTION INVENTION.

"Felix" seems to be giving me a piece of his humour over this. Allow me to inform him I know quite well what the Patent Office can give; my name is enrolled amongst those who seek its protection more

than once; but there is something the Patent Office does not protect, and while people try to rob inventors of their dues the grievance will continue. "Felix" has drawn a wrong conclusion from my article, and I shall revert to the subject again.

THE HEATHER SEASON.

This will be very late this year. We have failed this year in every other source of honey, and unless there is some fine weather during the Heather bloom there will be no harvest, as the corn is only in flower here, and it could not possibly ripen; also in the natural order of things all bees would be exterminated, as they have not food enough to last till Christmas. In 1879 we had a very cold wet summer, and the Heather did not open till August 26th; yet we have not had a Heather season to equal it since. Four weeks of hot fine weather would mean the best Heather harvest on record. Move your bees, place them a mile from the moors in some sheltered place, as I pointed out last year, then, should the weather prove bad, the stocks will keep strong. As a matter of fact, it would pay to move bees to the Heather from every part of the country, even if only to save feeding, provided they were in hives that could be fastened in a practicable manner for the journey. When the Royal Agricultural Society takes the bee department in their own hands perhaps they will provide a class for hives that will render migratory bee-keeping possible and practicable to all. Some for one thing, and most for another, we shall all remember the past season. I have had to feed all my bees all summer except one stock—these are Punie bees I have previously spoken so highly of; they have kept up their population, including drones, all summer, and if left to Nature, on the laws of the survival of the fittest, they would be the only bees remaining. Of course the season has not been a fair one to test any race, but this has always stood out very prominently.

"Felix" I see refers to the price of honey, and considers the sections should fetch 1s. 3d. each. If I may be allowed to express my opinion plainly, I should think the man who accepts less than 2s. 6d. each wholesale very unwise. The honey crop nearly all over America is as much a failure as here, and it was a failure last year. There is no country on the Continent where sections are largely adopted. The only other places are New Zealand and several colonies in Australia, but no more were used there last season than they will require themselves, and next season's crop could not be landed here before May, so why not demand 5s. each? If you get it, it will help to keep your spirits up in feeding for next season. I am working all my sections in glass, and not one will I sell under 5s., even if the Heather crop yields 200 lbs. per hive.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

- Little & Ballantyne, Carlisle.—*Bulb List*, 1888.
 Dickson's (Limited), Chester.—*Dutch and other Bulbous Roots*, 1888.
 Hogg & Wood, Coldstream and Duns.—*Catalogue of Bulbs*.
 James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea.—*Catalogue of Hyacinths and other Bulbs*.
 E. P. Dickson & Sons, Hull.—*Catalogue of Bulbous and other Flower Roots. Lists of Carnations and Strawberries*.
 Webb & Sons, Wordsley, Stourbridge.—*Bulb Catalogue*, 1888.
 Fisher, Son, & Sibray, 4, Market Street, Sheffield.—*Catalogue of Bulbs and Flower Roots*.
 J. Carter & Co., High Holborn, London.—*Bulb Catalogue for 1888*.

- All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (H. Williams).—Mr. William Sunley, Bacchus Hall, Moor Allerton, Leeds, was, and we think still is, the address of the Secretary of the Gardeners' Benefit Society to which you refer. It is a very good and well managed institution.

Hardy Herbaceous Plants (H. S.).—You can obtain plants of the less common from any of the florists who advertise in this Journal. Write to them for a catalogue, and you can select for yourself.

Striped Single Dahlia (A. T.).—We have seen similar varieties, but yours seems to be especially rich in colour. By all means preserve it, as it will be useful and effective.

Worms in Lawn (A. S., Glasgow).—The old remedy that has been hundreds of times mentioned of saturating the lawn with clear lime water is safe and effectual.

Asphalte Walks (G. D.).—Asphalte walks do not injure trees or plants growing in the adjoining borders, nor do they injure the grass of a lawn which they bound; nor would they injure Box edging unless the tar was allowed to run among it, which might be easily prevented by a board placed before it while the asphalte was being laid down.

Exhibition Roses (Curious).—As you appear to take special interest in the tabulated lists of Roses as prepared by Mr. E. Mawley, the "curious" point to us is that you appear to have missed entirely the very complete list published in September, 1887. Another list will probably appear during the autumn.

Exhibiting Plants (J. S. M.).—The plants named in the list are eligible for the prize according to the stipulations of the schedule, because there are not more than two of one genus in the collection. It is a curiously worded class, as two of the same species could be staged; thus the prize could be won by three pairs of plants—for instance, two of *Odontoglossum vexillarium*, two of *Oncidium macranthum*, and two of *Anthurium Schertzerianum*.

Specks on Potatoes (Inquirer).—The white specks on the skin of the Potato are common to some varieties, especially the rough-skinned, which are distinguished for high table quality. The specks are the rudimentary form of scab, due to the growth of a fungus (*Tubercinia scabies*) the spores of which are grouped in a globe around an air space. With the development of the fungus the spores are set free by the bursting of the skin of the Potato. There is nothing to cause anxiety in the present appearance of the Potato, as there is no evidence of disease, and the scab will not become serious unless the weather should prove unusually wet, or the Potatoes are stored in a wet dirty state.

Melon Pit (A. C. McI.).—You will find some plans on another page, as will "A Seeker for Information" on the same subject. We are obliged by your notification, and you are very welcome to what you have received. Several persons have become subscribers through seeing copies of the Journal sent or lent to them by friends. We are greatly obliged by such friendly co-operation, but it is not our wish that anyone should lose by the lending, and we willingly supply numbers, if applied to early, in the place of any that are disposed of in that way. We, like yourself, value the work of the correspondents to whom you refer very highly, and trust you will long derive pleasure and profit from their writings.

Annuals for Spring (J. W.).—A list of annuals suitable for sowing in the autumn for flowering in spring was published on page 108, the issue of the 2nd instant; but *Nemophilas* appear to be omitted. They often pass the winter well outdoors in suitable positions and thinned early. Well grown in pots they are very attractive. The same remarks apply to *Saponaria calabrica*. *Whitlavia*s and *Candytufts* do not always pass the winter safely without a little protection. Some of all the kinds potted and plunged in ashes near the glass of a light cold frame keep well. *Schizanthuses* raised at once and wintered on a shelf in a light greenhouse are beautiful in the spring when well grown. Ten-week Stocks also answer, and there is just time for sowing the London Intermediate for flowering in May, though the plants ought to be an inch high now. So ought *Schizanthuses*.

Rose—Primulas—Grapes (Kirkcudbrightshire Reader).—You must not prune the Rose or it will push fresh growths at the wrong time. Less water may be given than hitherto, but not keeping the roots so dry as to cause the leaves to flag seriously. If in good health it will flower well next year. It cannot have too much sun and air. Your Primulas have either been raised too soon, or received a check of some kind. All you can do is to pick off the buds, keep the plants cool, and give water judiciously. We know of no quick and easy method of removing mealy bug from bunches of Grapes. You erred in allowing the insects to get in, and will have no easy task in cleansing the Vines and house. If you can maintain a temperature of 65° at night, with air, the Gros Colman will ripen, but the Vine was not started soon enough.

Ants in Meadow Land (G. F.).—It is difficult to exterminate the ants without serious injury to the grass. The ground we presume is disfigured by hillocks. Those should be taken down level with the surrounding surface, and distributed evenly over the ground. A dressing may then be given of gas lime at the rate of 3 tons per acre, it being mixed with fifteen cartloads of compost—i.e., ditch cleanings, road sidings, or similar material, so as to insure its equal distribution, care being taken that the heap is not placed over the roots of trees, which would be seriously injured if not destroyed by the gas lime. It may be applied either in the autumn, or as soon after the middle of February as practicable. Allow it to lie a few weeks, and when in working order work it well with chain harrows. The gas lime may make the grass brown, but it will soon recover, and the ants will be driven away if not destroyed. The most effectual remedy of a manurial nature is perhaps the ammoniacal liquor from the gas works. We use it diluted with six times the quantity of house sewage, which includes all house and laundry drainage, distributing it with a liquid manure cart, one dressing

in early spring giving a luxuriant growth of grass and freedom from ant hills, with which the land was much infested.

Making a Fig Border (Subscriber).—A border of 3 to 4½ feet is ample for Figs that are to cover an ordinary width of trellis. It is necessary that it be well drained, a 4-inch drain being laid with proper fall and outlet to carry off superfluous water. Nine to twelve inches depth of drainage should be used, preferably chalk or brick and mortar rubbish, roughest at the bottom and finest at the top. The border should be not less than 18 inches, and need not exceed 24 inches in depth. Good loam should form the staple of the compost, using the top few inches of ameliorated soil, and if possible with the turf. If of a calcareous nature so much the better, and if inclined to be heavy rather than light all the better. If light, add clay marl to the extent of a fourth; if very heavy add a fourth to a sixth of road scrapings. An addition of a sixth of old mortar rubbish freed of pieces of wood may be added whatever the nature of the soil may be, and a twentieth of steamed or crushed bones, the whole well incorporated, and the border made with the material moderately dry, so as to admit of its being well firmed. An allowance should be made of a few inches increased depth for setting. A 2½ feet width of border will be sufficient for the first two or three years. The cause of the fruit falling is usually due to immature wood—the want of sturdy, thoroughly solidified wood, stored with elaborated sap. It sometimes arises from over-luxuriance, which is fatal to successful fructification, and not infrequently to a check consequent on excessive evaporation and inadequate supplies of water or food.

Odontoglossum vexillarium—Quassia Water (Reader).—During the summer months this species will do fairly well with cool kinds such as *O. Alexandræ*, *O. Pescatorei*, and others. But from the beginning of October until May *O. vexillarium* should not be in a lower temperature than 55° to 60° at night according to the weather, whether mild or the reverse; the day temperature may rise 10° higher. In this temperature it will grow strongly, and is benefited by the cooler temperature of the cool *Odontoglossum* house from the time its growth is completed until October. The greatest success is attained by aiming at an intermediate temperature the whole year round. That suitable for *Cattleyas* is too warm for the species in question, and if grown with them it is very liable to be attacked with yellow thrip. A temperature between that maintained in the *Cattleya* and the *Odontoglossum* house with plenty of moisture is what is really required. This plant should be well elevated above the rim of the pot and the pots abundantly drained. The material for potting may consist of the fibry portion of good peat and sphagnum moss in equal quantities, with lumps of charcoal freely intermixed. On the surface there should be a thick layer of living sphagnum moss, which should be encouraged to grow. If the moss is kept growing the plant roots freely and abundantly near the surface. If you place a quarter of a pound of quassia chips in a gallon of cold water and boil for about twenty minutes, then when cool add another gallon of water, or even more, the solution will destroy green fly on *Roses*. It may be used stronger if necessary.

Culture of *Alocasia metallica* (L. M. S.).—The following note, contributed some time since by an experienced cultivator, will meet your requirements:—Very turfy peat and loam, broken up with the hand and mixed in equal proportions, with the addition of about a sixth part of the whole of well-rotted leaf mould, and a sprinkling of silver sand and charcoal broken up fine, is a compost that suits this *Alocasia* well. Supposing that you have a healthy young plant well established in a 6-inch pot and in need of a shift, it may safely be transferred into a 9-inch pot. The drainage should be carefully secured, and the crocks thinly covered with a layer of the most fibry part of the soil. The operation of shifting need not have anything peculiar about it different from any other free-growing plant. In placing the fresh soil round the ball be careful to preserve the strong fleshy roots, and keep the bulbous-looking base of the plant rather high than otherwise. It requires a high stove temperature to grow it freely, and a moist atmosphere is indispensable to a healthy development of the foliage. It should be placed near the glass, and carefully shaded from the direct rays of the sun for the greater part of the day from the 1st of April till the middle of October. To grow it with all the compactness and strength which it is capable of acquiring it should have plenty of room, and be kept quite close to the glass. When crowded among other plants, and far from the glass, it becomes drawn, and loses that massive and imposing appearance peculiar to it when well grown. With a high temperature—say 75° at night—and potted in open well-drained soil, it delights in a good supply of water, and under these conditions will in one season form a large handsome plant—an object well worthy of any extra care and trouble which may be bestowed upon it.

Rainfall Figures (Ignorant).—You say yourself and “many others who are not so well educated as more fortunate brethren” do not understand the figures which represent the quantity of rain recorded, and you cite the figures in the report from Derbyshire on page 168—namely, 7.95 inches, 10.10 inches, and 5.39 inches. It is not a question of great erudition, and several persons whom you describe as “fortunate” have simply gained knowledge by reading carefully, remembering what they read, and by asking questions and not forgetting the replies. You are evidently not so apt as some of your brethren in educating yourself, or you would not spell puzzled with one z, nor render the word figures thus—“figers.” You must have seen those words in print hundreds of times, yet not once in the way you spell them. Thus a lack of knowledge may be attributable to oversight or lack of observation. Rainfall figures have been explained before, but

we readily explain them again. In the majority of cases, as in the instance cited, an inch is divided into a hundred decimal parts. Fifty is half of a hundred, therefore 1½ inch of rain would be entered as 1.50. If the fall was a quarter of an inch it would be entered 0.25. If 1¼ inch 1.75. We think you will comprehend so far; but may possibly want to know why the “plain old way” of setting down quarter, half, or three-quarter inch is departed from. The answer is very simple. Because the rain does not always stop at those measurements; indeed, very seldom, and account has to be taken of the quantity between, hence the practice that we hope will “puzzle” you no longer after you have set down the figures in the following manner and added them together. 7.95 Thus you see they give a total of 23.44 inches, or 0.6 (six 10.10 parts out of a hundred) less than 23½ inches. If you wish to 5.39 know more write again. We have any amount of patience in endeavouring to aid gardeners in understanding what they 23.44 read.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*Taffee*).—1, *Lilium speciosum*; 2, *Achillea Ptarmica flore pleno*; 3, Insufficient without flowers; 4, *Spiraea Ulmaria*. (*B. B., Kenley*).—*Hieracium aurantiacum*. (*A. W.*).—1, *Cichorium Intybus*; the *Begonia* leaves were not recognisable. (*R. O.*).—1, *Calluna vulgaris*, the common Ling; 2, *Erica cinerea*; 3, *Erica tetralix*. (*E. M.*).—*Campanula fragilis alba*, very attractive and worthy of cultivation. (*R. D.*).—1, *Origanum vulgare* (Marjoram); 2, *Ruta officinalis* (Rue); 3, *Amberboa moschata*; 4, *Linaria purpurea*; 5, *Godetia rubicunda*. We hope if you send again you will attach the numbers, so that they can be seen without untying the ligatures.

COVENT GARDEN MARKET.—AUGUST 29TH.

MARKET quiet, with no alteration.

NOTES BY THE WAY.

FROM the self-binder reaper to the old reaping hook there is a long interval of gradual improvement in the manner of reaping, and it may be thought we have reached as near perfection as possible in the self-binders now to the fore. But have we? In order to give a correct answer it will not suffice to point to the excellent work done last season when crops were slight and the barometer stood at set fair all through the harvest, but we must see what is being done under the adverse conditions of broken weather, a heavy crop of straw, and much laid corn. In a recent journey through five counties, in all of which harvest work was going on, we did not see a single self-binder at work. The ordinary reaping machine, scythes, and in two instances reaping hooks, were in full swing, to the entire exclusion of self-binders. Of course there are fields of corn erect and clean enough for the self-binder, but so much corn is not in this satisfactory condition, that the more simple implements are used of necessity. No doubt the self-binder is a triumph of mechanical ingenuity, and it is a labour-saving appliance under certain conditions, but failing such conditions it is the embodiment of a costly blunder. Any farmer will find this to be true if his corn is twisted about by wind or beaten down by rain, and he, trusting to the self-binder, has failed to secure enough labourers to get through the work without it.

Steam diggers come under the same category of costly blunders in a wet season. In the drought of last year, when there was no difficulty in finding a hard and sufficiently even surface to use them upon, they were so successful that they were proclaimed the coming power, by means of which the land would be brought under such thorough and improved cultivation that crops would be doubled and the agricultural depression at an end. This year, with the surface of the soil saturated by rain, we hear of wheels clogged so heavily by mud that they failed to propel the engine, and the forks could not enter the soil deep enough to make good work, or sometimes they would enter deeply, and others not half deep enough, so that a very uneven surface was left behind. Well, we do not at all object to a little irregularity of surface so that the soil is well stirred, but for such wet seasons as the present an implement dependent upon a traction engine passing over the land in front of it, for motive power cannot answer. Clearly it was a recognition of this evil which led to the introduction of the steam cultivator with its two stationary engines at each end of the field. The cultivator is efficient, and what is wanted to render it complete is motive force sufficiently powerful for the work at a very much cheaper rate than it is to be had at present. Are we to obtain this from electricity, or can it be had from a petroleum engine? Surely implement manufacturers would do well to turn their attention to this, for it is certain that if the requisite amount of power could be had from engines costing only a few pounds, and which, like the Otto gas engine, could be set going at full speed in a minute, not a farm would be without one or more of them.

It is quite certain that for any implement, or so called labour-saving appliance, to be really efficient, it must possess that simplicity which insures its use irrespective of weather. Here the single plough is undoubtedly triumphant, and it may be taken as the embodiment of a principle so sound that it cannot easily be driven off the land. The term "chilled iron" is now much used for what is sold as a superior sort of ploughshare. The merit of such shares consists in always having a sharp edge, and this is managed in this way. In casting the ploughshare the lower surface is in contact with iron, and this insures that part of the share becoming chilled, or intensely hard, while the upper surface is

comparatively soft, so that in use the upper part of the share is wore away first, and the lower hard part retains a thin sharp edge. So much for the now famous chilled ploughs, the merit of which, if we understand it aright, simply consists in the use of chilled shares, which, always having a sharp cutting edge, may be used with greater facility than those with ordinary shares. For light sandy soil double ploughs are invaluable, doing the work exceedingly well in half the time of a single plough, and the draught is so light in such soil that there need be no extra outlay for horses. It must be understood clearly that these advantages are only to be had by light land farmers, yet we have known double ploughs to be purchased for heavy land, only to be thrown aside in disgust.

WORK ON THE HOME FARM.

So far the corn has, on the whole, come down in satisfactory condition, but the work has been much hindered by showery weather. The Wheat bids fair to yield a full bright sample when fully ripe, but the ripening is much hindered by dull weather, and progress with harvest work is at best very slow. Reports of the probable yield here and in other countries tend to show a probable scarcity of supply, and a proportionate increase in price. Australian, Oregon, and Californian Wheats now realise 38s. per quarter, and this fact makes us hopeful that home-grown Wheat of this season may reach the desirable and profitable rate of 40s. per quarter. Of Indian Wheat we are told that owing to the bad harvest of last year and other causes the price is, on an average, 33 per cent. higher than it was last year, and that at present rates exporters can make no profits. All this may probably be regarded as affording no very sound basis whereon to found calculations of prospects or results of the home crop; but it is at any rate calculated to cheer and aid us in our efforts to save the Wheat under adverse conditions of weather. Everything would seem to show we "touched bottom" in the price of Wheat last year, and that we have reasonable hopes of a favourable reaction in prices this year.

Of Barley we have only mowed one field of twenty acres, and we are still unable to say what the quality of the grain will be, for the matter is certainly doubtful. Really high-class malting Barley is likely to be scarce, but the grain generally is a fine bold sample, and quantity may in some slight degree atone for a want of quality in the final result. The slow ripening of the Barley proves a serious hindrance to harvest work, much of the Wheat having to be left out in shock for quite a week after the reaping, and on farms where there are no Beans corn mowing has come to a standstill. On very many farms corn harvest and haymaking are now being done together, and excellent hay is being made. The second growth of Clover layers is really an excellent full crop, which we prefer turning to account for sheep-folding rather than for seed or hay late in a season remarkable for unsettled weather. With a superabundance of food for sheep, and a full supply of hay, the ploughing-in of Clover for Wheat will be found profitable.

OUR LETTER BOX.

Clover Pest (R. M. S.).—The "stuff" which comes in patches among the Clover is the common Dodder (*Cuscuta trifolii*). It is a parasitical plant, its seed germinates in the soil, and the slender stems run over the Clover, affix themselves to every branch or leaf with which they come in contact, feed upon and eventually smother the plants. To eradicate it not only pare the soil containing the dead patches of Clover, but a margin a foot wide around them, and burn the whole on the spot, for if you attempt carrying the dead plants and pared soil to one large fire, seed of the Dodder may be scattered about to bring more of the pest next season.

REMARKS.

19th.—Misty morning; fair day, with a little sunshine.
20th.—Cloudy day, wet evening and night.
21st.—Showery early; cloudy day except for an hour or two at midday.
22nd.—Generally fine and bright, but heavy rain storms at 11.30 A.M. and 0.45 P.M.; warm windy afternoon.
23rd.—Dull all day, with drizzle from 10.30 A.M. to 1 P.M.
24th.—Bright morning, cloudy afternoon, heavy rain 5 to 7 P.M., dull night.
25th.—Generally fine and bright, except for heavy showers at 11 A.M. and from 1.30 to 2.30 P.M.
An unsettled week of average temperature but with very little bright sunshine.—G. J. SYMONS.

THE WEATHER RECORDS.

THE numerous weather records published in these columns during the past three or four weeks have been prepared in a much more instructive and interesting manner than we expected could result from our invitation. Meteorological data are usually supplied in a series of figure details or in tabular form, which cannot be said to furnish very entertaining reading, however useful they may be for comparison. Our correspondents have taken a practical view of the matter, and instead of confining themselves to bare details of temperature or rainfall have illustrated them by the effects produced on fruit and vegetables, the flower garden occupants, trees, shrubs, &c. This is exactly what we desired, and our best thanks are due to all who have so readily assisted in recording the results of such an extraordinary season.

There is a tendency to attribute the unsatisfactory appearance of many garden crops to excessive rainfall, but though heavy storms have occurred at intervals and wrought considerable damage on gardens and farms, yet the general effect is mainly attributable to other causes—namely, sunless days and low night temperatures. In the majority of districts it does not seem that the rainfall has exceeded the average for the first six or seven months of the year, and in some cases it is below the average; but there has been a much larger proportion of wet days than is usual during June and July, and compared with these months last year this is of course still more remarkable. In one record from Hampshire, for example, it is shown that in June, 1887, the amount of rain registered was 1.41 inch, while in the corresponding month this year 3.31 inches fell. For July in the same garden (Swanmore Park), the difference is much greater. Thus in 1887, 0.26 inch of rain was measured, but this year the record for the same month was 5.48 inches, and only 94½ hours of sunshine. At Horndean, also in Hampshire, 6.29 inches were registered in July, exceeding even one record from Westmoreland (Penrith), which is only 6.04 inches. From Cardiff Castle comes the heaviest record—namely, 7.35 inches in twenty-seven days in July as compared with 1.51 inch last year. These are examples of the heaviest rainfall records we have received, but in many other districts they range from 4 to 5 inches. In naturally dry, shallow, well-drained soils the gardens have benefited rather than otherwise, and several letters from the eastern counties refer to this, notably our correspondent at East Dereham. With a rainfall for July of 4.80 inches, he says, "It has been, on the whole, a fine time for this light sandy soil." All the writers do not take pessimistic views of the situation, but few perhaps are so happily constituted as one of our Nottingham contributors, who remarks in a contented way, "The wet, cold, and sunless weather which characterised June and July, and at which I have, with the rest of Britons, growled—ungrateful sinners!—has come to me, I am constrained to confess, full of benedictions. I have forgotten the frowns of June and July in the smiles of August. My water cisterns were empty, they are now full. My garden was gasping for rain; it is now full and plenteous with all manner of good things. The ladies get baskets and baskets of flowers daily, and plenty of fruit, and the cook is smiling and satisfied; what more can a gardener want?" Unfortunately the "smiles" of early August have been followed by very heavy "frowns," which have not increased the happiness of gardeners or farmers. Still the replenishing of springs is a public advantage that will compensate for many evils of a more partial character.

No. 428.—VOL. XVII., THIRD SERIES.

Regarding the temperature the Hampshire record may again be noted as that of a favoured district. It is stated—"The temperature reached 80° in the shade on six occasions only in June, the highest being 83° on the 24th. The lowest temperature registered was 42° during the night of the 17th. On ten nights only was the temperature above 50° during the month. July did not produce a single instance of the temperature going above 70°; this the highest on the 14th, while on fourteen occasions only did the heat reach over 70°, as against thirty-one times in 1887. The lowest temperature this year was 39° on the 9th, while on nine occasions the temperature was below 45°. On sixteen occasions during June last year the temperature was 80° in the shade, while on three days it went over 90°. During July last year the temperature reached 80° twenty six times. Nine nights only registered a heat below 52° during the month." In eastern and northern counties slight frost was registered on several days in July, not sufficient to do any material damage, but as one observer says, "Kidney Beans hung their heads a little." At Lockerbie in Dumfriesshire, however, as in other districts of Scotland, the cold was much more severe. On June 5th there were 7° of frost, and on the 30th 2°. In July there were 3° of frost on the 1st and 8th, 2° on the 11th, and slight frosts subsequently. In East Lothian the June frost did much damage, the earlier Strawberries were rendered worthless, Potatoes and Kidney Beans being similarly injured.

Kitchen garden crops have been generally fully a fortnight late, in some places even more; but one result of the rain has been a vigorous growth that in the case of most vegetables, except Peas and Beans, has been rather welcome after such a season as last year. Potatoes are disastrously diseased in too many gardens, a few have escaped, and some are only slightly affected, but the total loss is heavy. Small fruits have been plentiful, but watery and flavourless, not keeping well, and in the case of Strawberries more particularly many have decayed on the plants. Pears seem rather scarce, but Apples are a fair crop in a number of gardens, also Cherries and Plums, but the long-continued rain has not suited the stone fruits. Tomatoes outdoors appear to have failed everywhere.

With the flower garden department most of the returns have dealt rather fully, probably because the weather effects have been most discernible there, especially where tender plants are largely employed. Respecting Pelargoniums the almost unanimous verdict is "plenty of leaves but flowerless," as applied to the Zonal varieties; the bronze and variegated types have not, however, coloured or grown well, and many beds even now are thin. Very rarely have these plants given so much dissatisfaction, and where they are mainly relied upon for colour the display has been correspondingly dull. One variety has endured the weather comparatively uninjured—namely, Henry Jacoby, and this is mentioned in favourable terms by several correspondents, as it also is notable in the London parks. West Brighton Gem and Vesuvius have "braved the storm" fairly well. Alternantheras have had a bad time, as the cold prevented growth and the sunless days gave them no chance to colour, most of the red-leaved varieties except *A. versicolor* being quite out of character; the golden forms, on the contrary, have brightened up surprisingly, and together with the golden *Spergula pilifera* have furnished the chief colour in carpet beds.

The borders of hardy annuals and herbaceous plants have been most valuable this season, as though many of the delicate plants have suffered, there have been plenty of others to take their places. Ten-week Stocks have succeeded well, as also have Phlox Drummondii, Mignonette, Nemophilas, Godetias, Linums, and Eschscholtzias amongst other annuals. Of perennials a long list might be given, but some that have given most general favour are Violas and Pansies, Pæonies, Veronicas, Spiræas, Campanulas, Pyrethrums, Delphiniums, Antirrhinums, Aquilegias, Irises, Pinks, Iberis, Phloxes, and Tuberous Begonias. Quite a chorus of satisfaction is expressed concerning the last-named plants, which have to some

No. 2034.—VOL. LXXIX., OLD SERIES.

extent taken the place of Zonal Pelargoniums, and they seem regardless of the weather. Shrubs and trees have profited by the moist season, growing strongly, and retaining a fresh green tint. Rhododendrons have flourished, but the weather is against the maturation of the wood and buds, while Conifers have made astonishing progress in many instances.

It might be added that we have had nearly fifty communications from over thirty counties in England, Ireland, Scotland, and Wales, so that a good general idea of the weather effects can be gathered from them. It is interesting to notice what a large proportion of gardeners take careful meteorological observations, the majority registering rainfall and temperature. Such records are often very useful for after reference, and in any case it is important to all gardeners to study the weather closely.

NOTES ON ALPINES.

PRIMULAS.

THE heavy and continuous rain of the present season seems to have suited many Alpine Primulas, and particularly those which come from the Himalayas; indeed, it is not merely confined to this group, for all the cortusoides (Sieboldi) section seem more vigorous than usual, and still retain their foliage, which latter in recent years has been more or less scorched and decayed. Our native Primroses, single and double, all have been benefited by the oft repeated drenchings of rains, which seemed for the time to be without end. This heavy downpour, coupled with the absence of sun for so great a period, seems to have thus far favoured a few shade and moisture loving plants, and the Primrose among the number. In a mixture of light loam, to which abundance of sharp grit has been added and about one-half of thoroughly decomposed manure, *Primula viscosa nivea*, the Snowy Primrose, is remarkably vigorous, and for some time past pushing forth white fleshy roots in abundance from the collar of the plants, a circumstance far from common in summer time, and with this particular plant. *P. rosea* was never more happy, while *P. cashmeriana* seems inclined to become rampant, and if a comparatively fine autumn ensues one may look for some fine heads of bloom from these two last named in the spring of 1889.

ARNEBIA ECHIOIDES.

The *Arnebia* has made more than usual headway, and is one of those easily grown plants which will eventually find its way into many gardens. It is not a difficult plant to grow and as slow to increase as was represented to us eight or ten years ago, but on the contrary lends itself most readily to two or three modes of propagation. It is alike suited to rockwork or front row in the border, thriving well in a rich light loamy soil of good depth. The clear sulphur yellow of its flowers have perhaps but one rival in the Alpine Wallflower, *Cheiranthus alpinus*, the dwarf cushions of which in spring time render it highly desirable among other good things in the spring garden. It may be that in a few years the *Arnebia* will become more plentiful, and nurserymen will reduce their prices for it accordingly, for good and choice as it now is, I venture to predict that the greater demand for it, which a reduction in price would bring about, would prove highly beneficial to the vendor. The fact of its perfect hardiness and robust constitution are points which all growers of it will fully appreciate.

DIANTHUS ALPINUS.

The glossy tufts of this Alpine Pink are not without beauty, even when its flowering is completed, and considering its vigour and free growth I am inclined to regard it as among the very best. Since its flowering in the early part of the year I have rooted some cuttings, which strike freely in moist sandy soil, kept close and shaded in handlights. As this species is somewhat variable from seed, it is a good rule to flower them all, discarding the inferior ones, and increase the best forms by cuttings; these root readily any time from May or June till the end of October. As it is impossible to have such a one in too great a quantity, I strongly advise all lovers of Alpines to strike quantities of cuttings annually and plant in patches on the rockery in moist sandy loam. It is one of the brightest of Alpines, and worthy the best culture. It may also be grown well in pots. One or two items seem essential to its well being, and these need plenty of water in the growing season, and a comparatively dry snug position in winter. Its rosy crimson flowers in spring are most charming and not easily matched. Speaking of Alpine Pinks reminds one of the other species near akin, such as *D. glacialis* and *Fischeri*. All these succeed in moist gritty loam in sunny well-drained positions.

ACANTHOLIMONS.

A. venustum still has the reputation of being rare, and certainly its slow growth will do much to keep it in this position for some time. Its occurrence in lists of Alpines is as rare as it is in private collections of these plants, and quite apart from its near ally from Mount Ararat, *A. glumaceum*. The last named makes a very pleasing edging and grows well in ordinary sandy soil in a good position. In spring its spiny tufts are covered with small spikes of rosy pink flowers, which are very pleasing, and whether placed on the rockery or used as an edging it is alike charming, and, by reason of its free growth, it should be planted in large patches to provide a good effect. In its culture an annual dressing of equal parts of sharp grit, thoroughly decayed manure and leaf soil worked well into the tufts will be found of material assistance to the plant, and if an increase of stock is needed it may be done at the same time in the following manner: Select a tuft and strip a number of the growths half off; semi-detach them as it were from the plant at the main stock, at which point will be found a heel; work your sandy soil well in, and give a watering when complete to settle the soil. The shoots thus treated will by spring have made nice roots, and may be detached at will; it may also be increased from seeds.

A. venustum may readily be distinguished by its rosy crimson flowers and semi-glaucous tufts of spiny leaves. It is thriving admirably in rich loamy soil with plenty of grit and abundant drainage. To these I can only add that it has occupied a position quite contrary to that usually recommended for it, which is a south exposure on the rockery, by being in a cool shady spot where abundance of water has been given it. Notwithstanding this, it is perfectly happy and growing more vigorously than I remember having seen it before. This charming plant and its propagation is worthy a study in itself, and I am attempting some experiments with it which I hope to record by-and-by; meanwhile let all those who possess it strive likewise.

OURISIA COCCINEA.

There are few plants to compare with the brilliant scarlet flowers of this *Ourisia*, and few plants more easily accommodated when its cultivation is fully understood. It loves a cool moist place in loamy soil, not necessarily heavy, but well drained; a deep moist sandy loam is far preferable to a heavy loam, cold and retentive; it will linger and die in the latter. Some years ago I had a grand specimen in a pot of this, which was the admiration of all who saw it. The position occupied by it for some two years or more was in a frame devoted to choice Alpines, and the soil employed was similar to what a grower would give his *Chrysanthemums*. One large plant occupied a 10-inch pot, and its vigour and free growth may be easily imagined when I say that it grew over the rim of the pot and half way down the sides. Not the least interesting feature with this plant was the fact of its being covered with spikes of its brilliant scarlet flowers the ensuing summer; indeed, so conspicuous was it that my employer requested that a prominent position should be given to it, that the numerous visitors might see it to advantage. Abundance of water was given during the spring and summer. The *Ourisia* on a cool moist surface will make roots in its onward course as free as any plant I know, and doing this the rest will follow as a natural consequence. It should never be placed on the dry exposed positions with hardly any soil near, and for which the pseudo-name of rockery has been given. It loves a deep soil at all times—this, with moisture, are its chief requirements.—J. H. E.

MILDEW ON STRAWBERRIES.

THE drought of last summer resulted in Strawberries being attacked generally by mildew, consequently those forced indoors last spring fell a prey to its ravages. I have observed, that when plants outside are attacked, and those required for forcing are raised from them, that they suffer in a corresponding manner. It is clear, therefore, that the spores are carried on the plants into the forcing house, and when the conditions are favourable it springs into activity and completes its work of destruction by the time the plants are in flower unless strong measures are taken to arrest its progress.

There can be no doubt whatever that drought is the main, if not the sole, factor in bringing this parasite, although other conditions, such as a continuance of cold, damp, sunless weather, might bring it into existence. We have grave doubts, however, on this subject, for observations point conclusively in the opposite direction. It has been noticed on plants when the weather has been the reverse of warm and dry, but these conditions have generally followed spells of bright hot weather and winds that have dried up the soil to such an extent that to keep the plants well watered has proved a work of some difficulty. Plants outside last season were

attacked to a much more serious extent than has been the case for the past nine or ten years, and the same may be said of those that were forced. Early this season mildew made its appearance outside before the flower trusses were above the foliage. This was due to the drought, for the plants displayed signs of suffering before heavy rains fell in June. A careful examination of the plants proves that cold wet weather is not favourable to the growth of mildew, but has had the opposite effect. Its ravages on the foliage are still visible, but it practically succumbed after rain commenced falling. Carefully noting the plants indoors and the atmospheric conditions under which it luxuriated indicates the same fact. The pest was at home on plants arranged close to the glass where the atmosphere was hot and dry, while in small houses with the plants some distance from the glass and in a moist temperature it scarcely made its appearance.

When plants are grown in large numbers outside the labour that would be required to destroy or even check mildew would render the work impossible, but when grown only on a moderate scale it could be stamped out without difficulty. It should be destroyed on plantations from which runners are layered, then considerable labour and loss would be avoided during the forcing season. Once the fruits are attacked they are nearly valueless, for they present a dull shrivelled appearance. Very seldom do the plants become so badly infested outside as to destroy the fruit to the same extent as is the case with fruit inside when the atmosphere is of such a nature to encourage its growth. If allowed to spread until the spores float about in the air of the house its destruction is a hopeless task. When it reaches this stage, which it quickly does, dipping and syringing with insecticides is of no use. Where mildew was not destroyed on the plants from which the stock for forcing has been raised, attention must be devoted to them during the winter to avoid an attack in the spring.

Some varieties of Strawberries do not fall a ready prey to mildew, therefore it will only be necessary to operate upon such varieties as Sir Joseph Paxton, President, and others. Vicomtesse Hericart de Thury appears to be proof against it, for I have never seen a trace upon it; even solitary plants associated with numbers of Sir Joseph Paxton kept perfectly clean while every one of the latter were attacked. The best method is to select fine settled weather and thoroughly syringe the plants with a solution of flowers of sulphur and water. A 4-inch potful of sulphur stirred into 4 gallons of water will be strong enough to kill this pest if a few fine bright days follow; but one application may not prove sufficient to insure them against an attack in spring, though I have scarcely ever known it fail or been troubled with mildew when the work has been properly done and the plants have the treatment they require during the forcing season. Last summer our plants of Sir Joseph Paxton for forcing displayed very little signs of mildew, consequently they were not syringed, and they suffered severely in spring. When dipping them, as we advised last autumn, before starting as a remedy against aphides and red spider we stirred sulphur into the solution, and on none of these plants did mildew make its appearance, but in every instance the plants of this variety that were not dipped suffered more or less according to the position they occupied and the amount of humidity that could be maintained in the atmosphere. In the future our plants will be syringed while they are outside if any trace of mildew is to be found on them, for the work as well as the solution is simple, and a large number of plants can be done in a very short time. Sulphur applied in this manner does the plants no harm. Dipping before starting the plants certainly takes longer, but those who practise it will find the time occupied well spent. Mildew on outside plants can be readily destroyed with the same solution.

When the plants are attacked in the forcing house no half measures must be adopted, or the fruit will be injured, if not ruined, in a very short time. For instance, if the plants are attacked just as they coming into flower—very often it shows itself at this stage—and they are left until the fruit is set, the plants may as well be thrown away. Often the flowers fail to set, and even if they do set they never swell kindly afterwards, the seeds only appear to grow, while the flesh is hard and never colours properly. I have seen it stated recently that a large grower removed a good portion of the foliage as a preventive. Such a remedy is nearly as bad as the disease, but I doubt very much that any such practice would be followed. It is far easier to believe that the foliage was attacked and the leaves removed in the early stages of its growth to stop it spreading to such an extent as to ruin the fruit. It can be kept under by this means if taken in time before it has perfected spores that are driven in every direction by the slightest movement of the air in the structure. I have tried nearly all the popular insecticides, and they are practically useless for arresting its progress, even at a strength that will injure the fruit and plants. The only certain cure is to dip the plants, or syringe them thoroughly with the solution I have recommended, and if left on

the foliage two fine bright days it will prove effectual. If possible this should be done before they flower, directly the first speck can be seen. If it shows itself when sufficient fruits are set for a crop the whole may be dipped or syringed, fruit as well as foliage. When the fruit is ripe no trace of the sulphur will be found adhering to it if they are thoroughly and liberally syringed with clean water. Until last season we should have hesitated to put into force such a practice, but some plants were so badly attacked that it would have ruined the fruit. Having nothing to lose we tried the course I have pointed out, and with good results, for it saved the crop, the fruit being a good colour, but not quite so large as it otherwise would have been.

This mildew will not spread on Vines, so that anyone having plants attacked in a vinery need not be alarmed. Some bunches hanging closely over infested plants certainly showed traces on the small berries that fell out when the bunches were shaken after the berries commenced swelling, but no trace could be found on the others.—WM. BARDNEY.

BORDER CARNATIONS.

IN some districts and on some soils these seem to flourish without much attention. Old plants with an annual dressing of loam will grow for years in the same place and make huge clumps; but such treatment will not answer in all soils and situations, as many gardeners and amateurs can testify to their cost. The compost in our Carnation beds is specially prepared for them, yet we dare not trust to old plants left undisturbed all the winter. Even the old common red Clove presents a miserable appearance in spring, and more than half of them die if left in the beds in winter; and this applies to plants only a year old.

Last autumn, when taking up the young layered plants, we decided to lift the old plants also and transplant them; but, notwithstanding this was carefully done and fresh loam placed round their roots, they have again failed. Many of them died in spring, and none is satisfactory. Such plants are also very deceptive. They look well all the winter, but when the season is a little advanced and the sun gains power they suddenly collapse, and the bed which ought to afford interest and pleasure is a source of annoyance and disappointment. Wireworms are very destructive to Carnations, and plants attacked by them will go off in much the same way as described above, but they are not the cause of the disease under notice. If the old stems are uncovered and examined early in the spring they will be found longitudinally split, and unless the wound be very recent there will be multitudes of small white maggots; but they are not the cause but the effect of the wound—they are such as can be seen in any decaying vegetable matter. This is no new disease, but the query is, Why should it be so prevalent in some districts and so seldom in others, and these often in close proximity to each other? At one time I considered it was entirely the soil at fault, and there is no doubt that cold close heavy soil very much aggravates the evil; but having thoroughly drained and filled the beds with a specially prepared compost with no better results, I am convinced there must be some other exciting cause, and this conclusion is confirmed by the fact that not many years ago border Carnations flourished and grew into huge clumps here without any attention whatever. But this was before my arrival, and it is a point I cannot understand, because our soil is naturally heavy, cold, and wet, resting on a hard impervious clay.

Perhaps correspondents can throw some light on this erratic behaviour of border Carnations. In the meantime I would advise those troubled with this kind of disease to layer without delay all the stems which are long enough and to make the short ones into cuttings. If these are dibbled into a half-spent hotbed covered with 4 inches of light sandy soil and half an inch of sand on the top they will be rooted in a month. The frame must be kept shut and shaded during the day, but a little air should be put on in the evening, as if kept too confined they are liable to damp off at bottom, and sometimes they will grow at top, which is detrimental to root formation. When rooted they should be potted either singly in thumbs or in pairs in 4-inch pots, using three parts loam and one part each of leaf mould, Mushroom bed manure, and sand. After potting return them to a cold frame and keep close for a few days until they have taken to the fresh soil, after which they must have plenty of air all through the winter. They should, if possible, be plunged in cocoa-nut fibre or other light material about an inch above the rims of the pots with their tops about 6 inches from the glass. The light should be drawn entirely off except in very severe weather, and even then a little air will be beneficial, the object being to prevent their growing as much as possible, for being easily excited they will make small weak growths if kept too confined, and then no one need expect good results to follow. Those layered should be also potted in autumn, or, what we have

found better, tied up firmly in moss ; they should then be treated as described for cuttings.

Having secured a good stock of young plants the old ones may be thrown away, and if the beds are to be planted with Carnations in spring they may be prepared at once. Carnations are very fond of maiden loam, fibrous and sandy, and about half decayed, so that after removing about 9 inches of the old soil, it being refilled with new as above, good results will follow ; but such soil can very seldom be spared for such a purpose, neither is it essential to good Carnation culture. If the beds are wet and heavy lay on 2 inches of quicklime, and if to hand 6 inches of fine ballast. This should not be merely dug in the usual way, but it must be thoroughly mixed with the soil through its entire depth. In February it should be again turned over, and this time work in a good quantity of soot, bone meal, leaf mould, and Mushroom-bed manure. If the soil is light and in good workable condition it will only be necessary to work in a good quantity of half-decayed manure, and leave it to the action of the weather all the winter. The first week in April is quite early enough for planting out Carnations in cold districts, and if the plants have been properly attended to all the winter they will be strong and stocky, such as will not fail to repay the cultivator for the extra pains taken. If a thick mass of flowers be wanted they must be planted thickly, 6 inches by 4 inches will not be too thick, but to give them a chance to grow and room to layer them they had better be planted 12 inches by 9 inches. Planting should always be done when the soil is moderately dry, for the best of composts may be spoiled by working on it when it is too wet. If new loam be used a sharp look out must be kept for wireworms, for a few of these will soon ruin a bed of Carnations.

An occasional hoeing and a good mulching of Mushroom bed refuse in June, is all the attention the plants require until the flowers appear, when they must be neatly staked. Should it be very dry weather an occasional soaking of water will be beneficial, but a good thick mulching is much better, especially on heavy soil, as if much water be used on such soil it runs together and cracks badly.—J. H. W.

GRAPES SCALDING.

I CAN fully corroborate what Mr. Wm. Bardney states as to the scalding of Lady Downe's Grape not being constitutional, but it must entirely be a "fancy" on his part when he states that the berries of Black Hamburgh will "scald" as badly as Lady Downe's if the "necessary precautions are not taken." It must be very bad management indeed for the Black Hamburgh to "scald," even at midsummer. We have not had any Lady Downe's scald this season, but then we took ordinary precautions. To prevent the berries of Lady Downe's from scalding, no moisture must be allowed to settle on them, as it will do very quickly if faulty ventilation is allowed, or even the pipes permitted to become too cool. It is false economy to allow the pipes to become cold, and I believe it is through this, and then keeping the house too close, so as to allow the temperature to rise, that causes the scalding. We have no fixed temperature, but work by the "feel" of the pipes, which are kept comfortably warm. About 2 inches of ventilation is left on the top, and about the same at the front, or even more, but we regulate so as not to cause a draught. At 6 A.M. more air is given if the morning will allow, and before the temperature increases. We like the inside temperature to rise with the outside. If sufficient air is not on, the least glimpse of sun will cause the moisture to condense rapidly on the berries. Probably the reason why the scalding of Lady Downe's is so prevalent this season is because those in charge have not been on the alert quick enough after a heavy storm of rain, which has necessitated the drawing up of the top lights even as often as five or six times during a day.—A. YOUNG, *Abberley Hall Gardens*.

FAILURES WITH TOMATOES AND MUSHROOMS.

I WAS pleased to see a chapter on "Failures" by "K. G." Like him I cannot see how gardeners can get along and be successful without having failures. Last year I tried to grow Tomatoes in winter and failed, because planted too late. The plants made good growth but set badly, the result of the short day and little sunshine. This year I am going to try again, but plant earlier, and by the time this is in print our plants will be in their winter quarters—viz., a span-roofed house from which Melons have been cleared. Half the Melon soil will be removed, and the Tomatoes planted in what is left. Two or three shoots will be taken from each plant and tied to the wires as they grow, and if we are favoured with a moderate amount of sunshine during the next two months I hope to have some fruit set which will hang through the winter and ripen early in spring. By this mode I expect to have

Tomatoes nearly all the year round. Last year we were only two months—February and March—without ripe fruits, and as they are much appreciated here I want if possible to have a good supply in early spring. The variety I am growing is Sutton's Earliest of All. We had it for our earliest crop last spring, and was greatly pleased with it. It fruited immensely and is of good flavour.

Another crop I have failed with here is Mushrooms, and I am most anxious to overcome this, but up to the present have been unable to do so. I have tried them in a heated Mushroom house, and also in an open shed, and have failed in both—that is, I have not had anything like satisfactory crops. I have had the manure from different sources, also the spawn, but with no better results. As my employer is very fond of Mushrooms I am naturally anxious to get a supply, and it is very disheartening when bed after bed fails. The only comfort is that I am told it was the same in my predecessor's time.

I know a good Mushroom grower who says he can grow them anywhere and in any house provided he has the right manure. I wish he would come and put up a bed here—I would gladly be his apprentice, and if he succeeded I would willingly own I was the cause of failure, but at present am not quite prepared to do so.—G. HILTON, *Smithills Hall Gardens, Lancashire*.

DAHLIAS AS DECORATIVE FLOWERS.

TAKING last season and the present one as types of extremes in summer weather, the one very hot and very dry, the other cold and very wet, Dahlias of all classes have come through the ordeal as well as any flowers we know. Last year they flowered early and continued late ; this year they have been later coming into bloom, though we have been cutting all sections of the flowers, singles, doubles, and Cactus since the beginning of August, and how late they will continue is a question of early or late frosts. But at any rate no flowers are standing the continued wet better than these, nor do any stand when cut better, a point of importance when so many flowers are so damaged by heavy rains that one day in the season renders them unsightly.

All varieties of doubles, whether selfs or fancies, are suitable for using as cut flowers. They are cut with long stalks and with buds and foliage, and use for furnishing large vases. The way we propagate these now is to break up the old tubers in spring after they have been slightly started, in order that no waste may be made through keeping tubers which are wanting living bud growths. These do capitally planted out in cold frames till wanted. The advantages of employing old roots are found in the plants flowering earlier and more abundantly, and in the greatly lessened risk of losing the tubers during winter. Cactus Dahlias are treated in the same manner, and in the matter of kinds wanted and quantities, cuttings are rooted in spring and kept in pots plunged deeply in soil through the summer months, these making fine plants the next year. In a season like the present young plants will hardly get into flower before winter, whereas from old plants treated as above, and old pot roots, we have an abundant supply now, and have had a good many throughout August.

Though it would be saying too much if it were stated that single Dahlias like a wet season, at the same time it may be safely said that they so little dislike it in comparison with many other plants, that a good supply of these is a feature of some importance in a season like this. They are easily propagated by division in the same way as the other sections, but after having had a very large number of named sorts through hand, I care to keep very few of these. The old white, alba ; Canary, yellow ; and Chilwell Beauty are the only named varieties grown in quantities. Carefully saved seed yields a very fine lot of plants with flowers quite as good as the majority of named varieties. The trouble of getting up a few hundred or even thousand plants is very slight—merely to sow the seeds in boxes in spring, when large enough to prick the seedlings into beds in cold frames, and thence to their flowering quarters at the end of May. A few flowers are sent indicative of the strain we have from selected seed.

GLADIOLI.—Since writing last week there are the following varieties to note in flower—viz. : 13 Shakespeare. 4 Bicolor ; a fine variety, salmon, with the lower petals creamy white. 2 Horace Vernet. 7 Caprice. 4 Opale ; a beautiful light sort. 1 Eugène Remy ; slaty purple, a good variety. 2 Arsinoë. 1 Mabel ; light variety, fine long spike. 2 M. A. Brongniart. 2 Archduchess M. Christine. 12 Panorama. 2 Diamant. Of Lemoine's varieties : 1 Etoile. 2 Marquis de Saporta ; scarlet. 1 Emile Lemoine ; a very pretty sort, with small dark flowers. 1 Sceptre d'Or ; straw-coloured and yellow flowers, very small, but pretty. 1 Bossuet ; shining, suffused scarlet, very fine. 1 A. Chenier ; small flowered

light variety. 2 Lemonei. 1 Talma; purplish blotches with grey ground.—B.

[Our correspondent sends some excellent blooms of single Dahlias, large, rich and varied colours.]

VINES AND DIPLADENIAS.

AN example of successful Grape culture under restricted conditions as regards the rooting medium was recently noticed in the gardens of Draycot House, Chippenham, and proves beyond doubt that extensive Vine borders are unnecessary when properly supplied with water. The house in question has done service as a vinery for many years, and is provided with an outside border, but the Grapes not being satisfactory, steps were taken to furnish the house with young Vines from an inside border. Instead of preparing an elaborate mixture, such as is generally adopted with these crops, some pure loam of good quality was obtained and deposited in an already existing narrow brick pit in the front of the house, after being provided with ample drainage. In this some young well prepared canes were planted, the old Vines being retained for supplying the crop until the young plants became well established, the older ones being well pruned to allow of good space for the younger Vines to perfect a sufficiency of leafage. The young canes have been planted a little over two years, and have furnished the whole length of roof, and also produced some beautifully finished samples of Grapes this season. Madresfield Court is represented by bunches weighing between 3 and 4 lbs., of excellent colour and very fine berries, and the same remark applies to Black Hamburg and other varieties.

The growth made is vigorous and short-jointed, and shows a tendency to early ripening, this latter condition probably resulting from restriction of the roots, the depth of soil measuring not more than 14 inches, and about a yard in width. Such a small quantity of soil is not as a rule calculated of sufficient bulk to carry Vines over so long a period, and it may be added steps are being taken to make additions in this respect before another season commences. No doubt the secret of success lies in the matter of watering, Mr. Gibson being an advocate for abundant supplies at all seasons. Liquid manure, too, is given unstintingly, and occasional dressings of Jensen's fish manure is considered important. Very great improvements are noticeable in the Muscat house; plenty of bunches of exhibition quality are produced this year, while previous to Mr. Gibson taking charge of the gardens the Grapes then grown were scarcely fitted for home consumption.

In the stove house are some very fine seedling Dipladenias of the amabilis type. These have been raised and grown by Mr. Gibson, and are the result of crosses between *D. boliviensis* and others of the Brearleyana and amabilis section, and constitute a very interesting collection. The blooms vary in colour from blush white through varying shades of pink down to that nearly approaching the deep scarlet of *D. Brearleyana*. They widely differ in shape and in size, some being as large as *D. amabilis*, while others are only a trifle larger than the old and useful *D. boliviensis*. They are not treated to large pots, but the vigour with which they grow testify to the careful attention bestowed on them by the grower; some of the shoots attain a length of from 12 feet to 18 feet. That they are heat-loving plants may be proved from the fact of their being grown in a house which has not had any ventilation for the past two seasons, and shaded only with lime applied through a syringe.

Seeing the ease attending their culture, it is unfortunate that such a beautiful class of plants should be so little grown, it being a noteworthy fact that in few gardens is their cultivation encouraged. Overwatering has been the cause of many failures with Dipladenias, and to guard against this an open compost consisting principally of peat and sand; abundant drainage should also be provided. They require a position close to the glass, and insects must be carefully guarded against. When well grown there are no plants that demand greater admiration than Dipladenias, and their usefulness for decorative purposes demands for them a position equal to that of Orchids.—W. S.

LITTONIA MODESTA.

NEARLY related to the well-known *Gloriosa superba*, this little plant is yet quite distinct enough to take generic rank, and though of an unassuming character as its name indicates, it is of graceful habit, and the freely produced flowers are brightly blurred. *Littonia modesta* is a native of Natal, where it was found by Mr. John Sanderson (together with many other novelties, including one named in his honour, *Sander-sonia aurantiaca*) during a journey in 1851 from Port Natal to Magaliberg. Most of the plants so found were transferred to the Natal Horti-

cultural Society's Garden, then under the charge of Mr. M'Ken. Some of these were forwarded to Kew, and amongst them the *Littonia*, which produced its flowers in April, 1853, "three months after the tubers were planted." Visitors to these gardens may have occasionally seen the plant in flower since, but it has rarely been exhibited, and this rendered the specimen shown recently the more interesting.

In habit it is much like the *Gloriosa*, having tapering leaves terminating in a tendril-like point, which aids it in climbing stems or twigs. The flowers are borne in the axils of the leaves, are drooping, and bright orange coloured. The tubers are of peculiar shape, brownish, and have

FIG. 23.—LITTONIA MODESTA.

been compared to a Spanish Chestnut, and the manner of growth is very curious. It has been grown in a stove and in cooler quarters, an intermediate temperature and sandy soil seeming to suit it best.

LONDON'S LESSER OPEN SPACES—THEIR TREES AND PLANTS.

NEW SERIES.—No. 9.

IN this autumn of 1888 the trees and shrubs round London, if we take them generally, are fresher and greener than they usually look. Partly this is, no doubt, to be attributed to the abundant rainfall, which has kept their foliage free from deposits of smoke and dust; also it is partly due, I think, to the fact that the coldness of last spring checked the opening of their buds, so that they did not put out an early and premature show of leaves, which have to come off before the full crop appears, and the result of which is to weaken the growth. It is very observable that in many parts of London where the ground has been much cut up by the opera-

tions of builders, by the laying gas and water pipes, &c., such trees as may be left standing often thrive more than others growing where the soil around is never disturbed to any depth. In some London gardens the fibres of the roots of trees seem to be entangled in a hard mass of clay, fatal to their vigour, and to this perhaps is to be attributed the death of the Oaks and Yews that once grew about London, which might otherwise have made their millenniums and been venerable memorials of the early history of the City. The tree which inclines to live the longest in the metropolis is the Elm, and this, if it escapes gales, is seldom spared by trunk-mining insects.

Some London suburbs retain just the characteristics as to soil which were noted by the older gardeners, in spite of the changes of time, but our sewage system tends to make them drier than when the rain had to soak in or run off by the streamlets to the Thames. In the vicinity of Vauxhall, for instance, or South Lambeth, our ancestors rejoiced that they had brooks, enabling them to refresh their plants with far better water than they could get from the Thames. One of these was the little river Effra, rising at Norwood and flowing past banks set with Alders and Willows, under which Queen Bess is said to have rowed to Brixton. The stream has vanished under ground, but moisture-loving species like these, and the varieties of Poplars are not uncommon. Thus the well-known Oval of Kennington is set round with Willows, even as it may have been when it was the nursery garden of Michelson, an old worthy not more thought of now than the Tradescants, who made South Lambeth notable as the first English home of a variety of European, Asiatic, and African species, which at some peril to themselves father and son obtained during the seventeenth century. John Tradescant is said to have grown the Rose to a great extent; he was also the introducer of exotic Ferns. About a hundred years ago the Royal Society sent out a special Committee to investigate whether many of the shrubs or trees he had set still existed, but the number proved to be small. Also it may happen that a tree survives while its history vanishes; for instance, I was shown at South Lambeth a Poplar free from all signs of decay and of unusually large proportions to which some traditional story belonged. I am told it has, however, died out with the oldest inhabitant; yet there are those left who can point out where Chandler's nursery was close to Nine Elms Brewery, if not on the same ground, formerly celebrated for its Camellias, Magnolias, and Wistarias. Mr. Chandler was also one of those who experimented with the Chinese Chrysanthemum while that group of plants was comparatively unpopular or unknown, and obtained a number of varieties.

But one of the specially interesting events of 1888 to the South London folk has been the formation of Vauxhall Park, as it is to be called, after a strong opposition had been got up which nearly succeeded in upsetting the scheme. This will be made up of three open spaces lying contiguous—a plot of ground called the Lawn, and the gardens of Fawcett and Caroone Houses. It is an historic spot, originally an estate of the Crown, part of the extensive demesnes at Kennington, where once was a deer park, arable fields, and extensive orchards. The name of one of its later possessors is retained by Caroone House, and the companion residence was in the occupation of a well-remembered Postmaster General for about twelve years, whose activity was so remarkable considering his sad infirmity. Of course the grounds must be remodelled, but I hope most of the trees will be preserved, and some also of the plants of humbler growth. Amongst the trees bordering the Lawn, or scattered over it, beside the large Poplar already mentioned (*Populus nigra*) were others of that species, also the Lombardy and the White Poplars; the first of these seldom attains any height in London. A few young Willows only. It is noticeable that of this large group, the two which are commonest about the suburbs are the White (*S. alba*), and the Bedford (*S. Russelliana*); the true Sallows in this genus *Salix* are seldom represented. Of course the foreign *S. babylonica* is not unfrequent in cemeteries and elsewhere. Here I found several Mulberries of medium size, interesting because old South Lambeth was famed for this tree, much fruit on them too, but not likely to ripen. Walnut trees reminded me of the vanished Walnut Tree Walk; these also had some show of fruit. In the garden of Fawcett House were Pears, Cherries, and, on a south wall, some good old Vines. There were only straggling bunches of Grapes, and few fruits on the Pears, but the Cherries, chiefly the old Blackheart, were full; it seemed odd to be eating fruit produced within sound of Big Ben at Westminster. Elm trees were represented, amongst them a goodly specimen of the broad-leaved variety (*Ulmus latifolia*), some very aged Hawthorns and Hollies, and of the Ash several fine examples, well-branched and symmetrical. Robinias were distributed over the grounds, now and then contrasting with the heavy foliaged Evergreen Oak (*Quercus ilex*), and the large-leaved Cherry Laurel. In the enclosed garden of Fawcett House were many old-fashioned flowers.

Some prominent favourites of his appeared to be *Eschscholtzias*, *Globe Thistles*, *Dahlias*, *Stocks*, and *Larkspurs*. A pretty effect had been produced by a cluster of *Digitalis* in one corner, but its growth this season was checked by a surrounding of *Hawkweed*. In another part where *Jerusalem Artichokes* had been planted these had been left to themselves, and the moist summer had drawn up the stalks to the height of 6 feet. It was curious to discover, upon one neglected patch, a profusion of *Melilotus officinalis*, a wild plant which has made itself conspicuous this season in North Kent, on land where it had been seldom observed before. I should add that the enterprise owes much of its success to the exertions of Miss Octavie Hill and Mark Beaufoy, Esq.

So many of the old market gardens of London have become the sites of unsightly or badly built dwellings, that it is quite refreshing to discover one which is to be preserved as an open space. Through the kindness of Mr. Minett, the fields near the Knatchbull Road, between Camberwell and Brixton, are being formed into a recreation ground, and the walling round is in progress, but at present the laying out has not been commenced. The extent is about ten acres. It had long been cultivated by a member of the Myatt family, with others. In the Camberwell New Road close by, was at one time the arboretum of Mr. Buchanan, which supplied what was then thought a surprising variety of young trees, especially evergreens. People flocked from all parts of London in the July of 1835 to see a large *Yucca gloriosa* which unexpectedly burst into flower, and was reckoned to have had upon it about 2000 blossoms. Flowers in windows and gardens are still plentiful along the roads of Camberwell, which have ceased to be remarkable for the displays of nurserymen, but encouragement to horticulture is given by the show in Camberwell Green. Its three acres are turned to excellent account, the borders being filled with herbaceous plants chiefly, and the choicer flowers placed in beds amid grass plots and railed off, a necessary precaution probably, though forbidding near inspection. The geometrical style of bedding is followed, and the placing here and there a Birch, a Poplar, an *Araucaria*, or a *Sumach* on the central space has a good effect. A screen of shrubs and young trees afford a screen from the winds, which sweep at times down from the hills near. It is likely that the churchyard of St. Giles's, Camberwell, will soon be opened to the public. This contains a great variety of shrubs, but no flower beds, and has a pretty avenue of Limes. In front of the church is an old Elm, and behind it a Plane nearly as venerable. Specimens of the Fir tribe, however, were, I observed, as reluctant to grow here as they generally are about London, their preference being a sandy or loamy soil.—J. R. S. C.

HOVEAS.

THIS genus consists of evergreen species, natives of New Holland. All of them are very beautiful, but somewhat difficult to get into a sturdy, bushy, compact habit of growth. The flowers are either purple or a deep purple blue, and are produced most profusely on the young well-ripened wood of the previous season, a fact which furnishes the key to their successful cultivation. Another recommendation is that they all flower freely in the early spring and summer months when flowers are comparatively scarce in other departments. I shall merely instance a few where all are beautiful.

HOVEA CELSII.—Habit rather straggling; height from 2 to 5 feet; leaves somewhat lanceolate; flowers deep purple blue, produced at the base of the leaves, often in whorls or masses; one of the most beautiful of the family, flowering generally from April to July.

HOVEA PUNGENS MAJOR is another beautiful species with blue flowers, introduced from the Swan River.

HOVEA LATIFOLIA.—A beautiful species with leaves broader and larger than *Celsii*; part of the flower the standard blue and the keel purple; the flower is also larger and the plant altogether more strong growing.

HOVEA ELLIPTICA, with roundish oval leaves; *H. ilicifolia*, with curled Holly-like foliage; *H. lanceolata*, spear-like leaves; *H. longifolia*, long leaved; and many more are all species having purple flowers, blooming from March and April to June and July, and worthy of culture where room can be afforded them, more especially as from 2 to 4 feet in height, and rather less in diameter, may be taken as their general range of growth when full justice is done to them; and all requiring similar culture, though *Celsii* perhaps, of all others, requires the greatest attention. I shall shortly allude to their general management.

PROPAGATION.—This is effected by seeds. Most of them will ripen their seeds, but very few should be allowed to remain, and only those from the first-formed flowers, for two reasons: the first is to prevent the plant being exhausted of its strength; the second

is to enable us to prune back the plant as early as possible after the beauty of the flowering season is gone. The seeds being obtained as early in the summer as possible may be dried and sown as soon as ripe, or they may be preserved in a dry cool place until the following March. In both cases they will be better for being sown in sandy peat, and then plunged in a sweet hotbed, giving more coolness and air as soon as vegetation has taken place. If not sown until the following spring steeping the seeds in warm water of 130° for twenty-four hours will cause them to vegetate sooner. As soon as the plants are a couple of inches in height they must be pricked off round the sides of a pot in sandy peat with a trifle of leaf mould, and kept close for a little time in a mild hotbed, or if in the heat of summer merely a close frame until growth has fairly commenced.

Cuttings.—These should be the points of young shoots getting a little firm in April and May, or, better still, some nice stubby side shoots about 2 or 3 inches in length cut clean off close to the stem, or so near as not to injure it. Cut a cross at the base with a sharp knife, and remove merely the leaves there and one or two above—success greatly consisting in retaining as many leaves as possible, and then taking care that these leaves should act as absorbers quite as much as perspirers by keeping them in a close atmosphere, and in as much, but not more light than they can bear with impunity. For this purpose the cuttings when made should be inserted in white sand over sandy peat well drained; in fact, in all these operations more than three parts should always consist of drainage. If the cuttings are placed round a pot inverted in the inside of a larger one success will be certain, and less trouble will be occasioned for drainage than by any other mode. When settled and firmed by watering, and allowed to get dry in the shade, clean conical-shaped bellglasses should be fixed in the sand around the cuttings, and then the plants should stand in a close frame or pit, where the heat will only be a very few degrees higher than what the plant enjoyed before the cuttings were removed. If during the day the heat from the confined air should become too high, and thus have a tendency to spindle the cuttings upwards—a tendency always increased by dense shading—it is better instead of thus increasing shade to damp that already in and give a little air at the back of the pit or frame to allow the heat to escape. From inattention to this we have known valuable cuttings so attenuated that healthy plants from them afterwards could hardly be expected without great future care and trouble. A moist close atmosphere is of the first importance in striking cuttings in general, shading from bright sunlight is another indispensable; but both may easily be carried to excess, especially if the temperature is allowed to rise to a great height. Where quick rooting is an object it is much better to remove the cutting pots after having stood three or four weeks in the cold frame to a mild bottom heat, say from 75° to 85°; but even here the top temperature should seldom average more than 50° by night and 75° by day, or in summer should seldom be much above what it is in the open air. If conical glasses are used wiping them will be more a matter of amusement than necessity, and lifting them for watering purposes will be seldom required, tilting up one side at night, and increasing the space by degrees, will be of more importance, taking care, however, to shut down close in the morning before the sun strikes upon them. I have several times shown that refracted light is better than shaded light, and that by placing cuttings at a certain safe distance from the glass shading might be altogether dispensed with—a matter of importance to amateur operators, who must sometimes depend for assistance in their absence to the not most willing hands.

FUTURE MANAGEMENT.—If the plants are struck early they should be pricked out round the sides, say four of them in a 4 or 5-inch pot, or singly, if strong, into 3-inch pots. For keeping over the winter it is generally the safest and easiest mode to prick out such small plants round the sides of middle-sized pots, as the moisture, temperature of soil, &c., are more equable than when each little plant has a pot to itself, while the trouble of attendance is greatly abridged. If the cuttings are not ready to be potted or pricked off before the middle of September, provided there is sandy peat below the silver sand, they will be kept safer in the cutting pots all the winter. In either of these cases the plants should be kept on a shelf near the glass, where they can obtain the highest medium temperature of the greenhouse in winter and abundance of air whenever the external air is not stormy, not loaded with moisture nor below 38° or 40°. In either of these cases the amount of fresh air (unless heated before entrance into the house) must be limited.

POTTING.—This is best done in the spring months in the case of young plants. In the case of established ones it may be done any time in summer after flowering when fresh growth has commenced. Where proper attention can be given after the plant is a foot or 18 inches high, it may be treated on the one-shift system; in all other cases the successive shift system should be adopted, and not

too large shifts at a time. I need not add that drainage must be particularly attended to. To prevent the access of worms, amateurs should use caps or bowls of zinc or galvanised iron inverted over the hole in the bottom of the pot, with plenty of rough, and then finer drainage above, surmounted by a little green moss or chopped straw to prevent the earthy matter clogging the drainage. If such a plant without some of these precautions is set in the ground, even for a short time, a worm or two will try and wriggle themselves in, and as the plants neither like much lime water, nor to be much disturbed about the roots when growing, there is a difficulty in getting the slippery gentlemen dislodged. The cap is one of the best means for keeping them out.

SOIL.—For young plants this should be composed almost entirely of fibry sandy peat, with a little dried leaf mould; as the plants get larger a little fibry sweet loam may be added. The larger the plant and the larger the shift the rougher should the compost be. For medium circumstances the compost will answer well of four parts fibry peat, one part very fibry sweet loam, one part silver sand, and one part of equal proportions of rough charcoal and pounded bricks or broken freestone. The largest pieces for a large shift should be less than a walnut, and the least, half the size of small peas, the very dust being sifted out before the sand is added. A slight layer of finer compost should be placed upon the surface.

TEMPERATURE.—After potting, at whatever time, the plants should be kept closer and warmer than usual to encourage growth, exposing them to sun and air by degrees. The common temperature of the greenhouse in spring and early summer suits them well when blooming, but when that is nearly over, and the plants have received their pruning, any close pit where a moister atmosphere and a higher temperature can be given them will encourage fresh growth. When that has taken place, the roots, if necessary, may be examined, and the plants returned to the same position, taking care, however, that they are more exposed by degrees before the end of autumn, so that the wood may be well matured; on this maturity depends, in a great measure, their winter treatment. Those best ripened will stand a low temperature and an abundance of air that would ruin those more coddled in the autumn. As a general rule the plants should seldom be below 45° in winter if it be desirable to keep them nice and healthy. A rise of from 10° to 15° may be allowed from sunheat. A slight shade will be wanted when growing in summer, but full exposure towards autumn. I have seen good plants that were never removed from the greenhouse, but I would prefer a closer and warmer place when making their wood than would suit the generality of greenhouse plants in summer; but if the greenhouse is kept close for the sake of growing Azaleas and Camellias, then that alters the case, and it would just be the place for the Hoveas when growing.

TRAINING.—The trellis one-sided system, especially for plants that have no liability to twist, twine, or creep, is very properly being discarded. Every appearance of twisting, even when done to give a bush-like character, detracts from the beauty of the lovely Hoveas. The bush system must be given at once, when the plant is young, by stopping, and by tying out the side shoots from the base of the plant to the side of the pot, fastening them there to little sticks, or, better still, by strands of fine matting or worsted thread to a ring fixed beneath the rim of the pot outside. This training must also be kept in view when pruning the flowering shoots somewhat freely previously to setting the plants growing for another year.

WATERING.—An essential point; the plants will neither endure the torrent spout system, nor the surface soil the dribbling from a fine rose. A medium between the two will be found the best, such as placing a large potsherd or a good-sized oyster shell on the surface of the pot and pouring the requisite supply slowly on these mediums. I have several times lost fine plants, solely, I believe, owing to the careless use of the waterpot. In winter the water should be pure, and not below the temperature of 50°. If enough is given at a time waterings will not often be required in winter. As the flower buds begin to swell more will be necessary, and a very weak solution of old cowdung will then be advantageous, but it must be weak and from old dung. When growing they must have abundance of water. During the whole period they stand on the shelves in the greenhouse, to prevent sudden extremes from sunshine, dry cold air, or brisk fires, the plants will be rendered more secure by standing in double pots, the space between them, at the top at least, being stuffed with moss or any other more suitable substance. When growing, the syringe may be applied often, but lightly, morning and evening. In winter and spring, before the flowers open, fine dustings may be given in the middle, or very early in the afternoons of fine, mild, sunny days.

INSECTS.—The most troublesome enemy is a white scale insect. Washing first with soap and water and gum water, and afterwards, in the course of twenty-four hours, with warm water, at a temperature not above 100° will be found the most cleanly, if not

decidedly the most effectual remedy. I have mentioned the temperature above, because, though I have cleared many plants of insects by dashing water against them at 130° and 140°, one experiment, at least, seemed to tell me but too well that the Hoveas would not endure it.—F. R. H. S.

SPORTS.

THE account of the sport which "Duckwing" has succeeded in propagating is interesting, and is just what is wanted if we are to learn anything of the nature of sports. It is plain that the Comtesse d'Oxford class is inclined to sport. I had a bloom of Mrs. Baker a few days ago, which was almost entirely splashed with white, after the fashion of Pride of Reigate, but it did not seem worth propagating. I hope that "Duckwing's" sport may turn out well; but, as I said in my last, he is lucky if he has hit upon a new and distinct shade in this numerous class.

THE ROSE SEASON.

It is early to offer any general remarks upon the Rose season; but now that September has arrived, I should like to continue my quota of observations on the weather in Suffolk during the summer months. May was very dry, and so was the early part of June. The hay was pining for rain during the whole of the growing season, and drowned directly it was cut. All through June we were looking for the burst of sun which so wonderfully changed the season of 1887 from a late into an early one; but it never came, though we had not much rain. July found us still hoping, but in vain: the cold and the wet increased. A good deal of rain fell during the first week; but in the neighbourhood of Ipswich, which has, I believe, about the lowest average annual rainfall in England, we had not much actual flooding rain till the last week of the month. Still July produced 5.20 inches, and we certainly had rain enough and to spare. Wet Julys I can remember, but never such a cold one. Never before, at any rate, did I have to go and warm my numbed fingers at a fire after cutting for the National Rose Show. Not a Rose opened or grew on the way to the Crystal Palace on that exceptionally cold night, and never surely was there such blowing of buds to be heard during "setting up," and such manipulations with budding knives and pencils to be seen.

EELS AND ROSES.

My Roses were fully out on July 16th, about ten days late. On that evening I noticed the "Midsummer Dors" (small cockchafer) swarming for the first time. These are generally very punctual at the end of June. On the morning of July 31st I went into my rosery to cut a nice lot of blooms, as I had hoped, for a wedding, and brought back in my basket eight fine eels, which I found in the Rose beds, washed out of the little stream which supplies my pool. I was very nearly sending the eels instead of the Roses. Stewed eels is not, I fancy, a usual dish at a wedding breakfast, but for my own part I would sooner have had them than those drowned, battered, and mudsplashed Roses.

A GLIMPSE OF SUMMER.

The only summer weather we have had was between August 6th and 15th, and the effect on the Roses was very remarkable. Varieties which open badly as a rule came out at once under the usual influence of a hot sun. In other seasons I have known blooms of La Boule d'Or stand for a week on a south wall in cloudless weather in July, and not open too much; but during the second week of the past August they completely expanded in the open bed in two or three days.

OUTSIDE THE ROSE GARDEN.

Everything has naturally been very late. The most noticeable instance that I observed was that of some fine old Lime trees in a park in this neighbourhood. These were in full bloom and filling the air with fragrance on August 15th. Bedding plants have been poor and annuals fair. Trees and shrubs do not seem to have made more growth than last year. Plenty of Pears, but no Apples. Strawberries poor, tasteless, and decayed. Raspberries, Gooseberries, and Currants were very large crops, but of course deficient in flavour. On the whole, I think, the season has been wonderfully productive considering the weather.—W. R. RAILLEM.

THE MIRABELLE AND GREEN GAGE PLUMS.

I SEND you some fruit raised from the Mirabelle Plum. The other seedling trees have produced small Mirabelle Plums. This variation gives some indication of the possible origin of the Green Gage.—T. FRANCIS RIVERS.

[This letter is short but suggestive. The origin of the famous old Green Gage has not been traced. The fruit sent by Mr. Rivers undoubtedly gives some indication of that origin, resembling very closely that of the Green Gage. One of the many French

synonyms of the old favourite is Mirabelle Vert Double, or Double Green Mirabelle, whatever that may mean. The "Fruit Manual" contains the following historical notes relative to the Green Gage:—

"This universally known and highly esteemed fruit has been longer in this country than is generally supposed. It is said to have been introduced at the beginning of the last century by Sir Thomas Gage of Hengrave Hall, near Bury St. Edmunds, who procured it from his brother, the Rev. John Gage, a Roman Catholic priest, then resident in Paris. In course of time it became known as the Green Gage Plum.

"In France, although it has many names, that by which it is best known is Grosse Reine Claude, to distinguish it from a smaller and much inferior Plum called Reine Claude Petite. The Green Gage is supposed to be a native of Greece, and to have been introduced at an early period into Italy, where it is called Verdochia. From Italy it passed into France, during the reign of Francis I., and was named in honour of his consort Queen Claude; but it does not appear to have been much known or extensively cultivated for a considerable period subsequent to this, for neither Champier, Olivier de Serres, Vautier, nor any of the early French writers on husbandry and gardening, seem to have been acquainted with it. Probably about the same time that it was introduced into France, or shortly afterwards, it found its way into England, where it became more rapidly known, and the name under which it was received was not the new appellation which it obtained in France, but its original Italian name of Verdochia, from which we may infer that it was brought direct from Italy. It is mentioned by Parkinson, in 1629, under the name of Verdoch, and, from the way in which he speaks of it, seems to have been not at all rare, nor even new. It is also enumerated by Leonard Meager in the 'list of fruit which I had of my very loving friend, Captain Gurle, dwelling at the Great Nursery between Spitalfields and Whitechapel,' and is there called Verdocha. Even so late as the middle of the last century, after it had been re-introduced, and extensively grown under the name of Green Gage, it continued to bear its original title, and to be regarded as a distinct sort from the Green Gage. Hitt tries to describe the distinction; but as he tries also to show that the Reine Claude is distinct from the Green Gage, his authority cannot be taken for more than it is worth; a remark which may safely be applied to all the pomologists of the last century. Miller laboured under the same hallucination as Hitt, for in his Dictionary he says, speaking of the Grosse Reine Claude, 'this Plum is confounded by most people in England by the name of Green Gage.'

"We have seen, therefore, that the generally received opinion that this valuable Plum was first introduced to this country by the Gage family is incorrect, but that it must have existed for considerably upwards of a century, at least, before the period which is generally given as the date of its introduction."

THE ROMANCE OF SEED-SOWING.

(Continued from page 172.)

IV.—RUPTURE.—By this I mean the various methods by which seed vessels—i.e., fruits—dehisc or open of their own accord, either in part, when the wind usually shakes the seeds out, or through their entire length, in which cases the contained seeds are more or less forcibly expelled. In this latter case there is complete self-dispersion, whereas in the former the opening of the vessel is the only part of the process entirely performed by the plant. Let us first glance at a few cases of complete self-dispersion.

In Bitter Cress (*Cardamine hirsuta*), a very common weed on dry, open banks, the pod at the proper moment when the seeds are ripe suddenly rolls its two side walls outwards and upwards, and the seeds, lightly attached to a central delicate membrane, are scattered 6 or 7 feet away from the plant. Even a puff of wind is sufficient to effect this purpose. Wallflower acts similarly, but with less force, as may be seen in any garden.

Among our wild Geraniums there are many interesting cases. Herb Robert, which everyone knows, has five seed vessels arranged around a central elongated column. Each vessel is prolonged upwards into a thin rod, which is at first attached to the column, but is slowly separated from it; the flower, which after blossoming turns downwards, now becomes erect, the rods become highly elastic, and presently separate from the column with great force, often scattering themselves and their attached vessels to as great a distance as 20 feet. We may find scores of these flowers in the woodlands, each of them with the erect central column alone remaining perfectly bare, and we must look for some time to find the scattered seed vessels far away.

In another, *Geranium dissectum*, or Jagged Crane's-bill, the rods remain clinging to the column together with the five vessels, the seeds only being thrown off. Curiously enough, the vessels split open on the side turned towards the central column, and it would almost seem as if this were useless, but the plant has its fashion of overcoming this difficulty. Just before the vessel splits the rod curls outwards, placing the vessel horizontally, and so at right angles to the column. The vessel gradually opens as the rod curls still more upwards, a delicate fringe of hairs keeping the seed safely meantime, until, when the rod has gone far enough to place the vessel nearly upside down, the hairs give way, and the seed is ejected. In this species, therefore, we should find the column not bare, but surrounded at its top by the five curled-up rods, each carrying its empty vessel with the inner face split and looking upwards.

In Dog Violet (*Viola canina*), the capsule is raised on a long stem, and at maturity opens by three valves, each holding a row of four or five seeds. The walls of the open valves now become dry, and contract, the two edges approaching each other. This after a time forces the seeds out with a jerk, throwing them 8 or 10 feet off. In Sweet Violet and Hairy Violet (*V. odorata* and *hirsuta*), the capsules are not so raised, the stem being almost absent, and the leaves all springing from close to the root. Here we find that their capsules simply open as they lie on the ground, suffering the seeds to fall out among the grass near by. Not being raised aloft, if the capsules shot their seeds, the latter would probably strike against the surrounding grass and fall back again, so the valves develop no contracting power, such being useless, and they simply open quietly. Dog Violet has found a better device for dispersion, and so in many generations has gradually developed a tall stem, from the top of which its elastic capsules can do their work with good effect.

In Common Balsam, or "Touch-me-not," the pod dehisces through its whole length, and at maturity, if we gently press the centre between the thumb and finger, it swells up under our touch, parts suddenly, and away go the seeds. I have stood at one end of a room 12 feet long, and by pressure caused a pod to throw its seeds with force against the opposite wall. Again, go and look at some of our Vetches, or at Broom in seed time, and you will find the pods split in two, with each half rolled or twisted on itself, and the seeds gone. The pods possess a layer of woody tissue at an acute angle to their axis. When this contracts the pod is, therefore, not curled up along its length, but twisted like a screw. Gorse, and some others of the Pea order, open with a sudden crackling noise and shoot out the seeds. On a hot August day you may stand by a clump of Gorse bushes and hear a series of tiny reports, as one by one the pods burst.

Two singular instances are worth notice. The fruit of the Sand-box tree (*Hura crepitans*) of America is about as large as an Orange, with a dozen or more deep furrows, which indicate as many internal divisions into carpels. When ripe, and under a hot sun, each separate carpel splits simultaneously, the whole bursting with a loud explosion. From this fact the plant has earned the *soubriquet* of the "Monkey's Dinner-bell!" Squirting Cucumber (*Ecbalium Elaterium*) is one of the Gourd order, and when ripe is full to tension of a viscid fluid. A very slight touch causes it to suddenly separate itself from its stalk, the sides contract, and through the end where it was attached, the whole contents, both fluid and seeds, are sent with a whizzing sound some feet in the air. An unwary traveller touching *Ecbalium* may quite easily obtain a baptism not to his liking. Intense heat causes spontaneous separation from the stalk without any touch. These examples of complete self-dispersion may suffice.

Of the cases where a partial dehiscence takes place, we may name a few. Mouse-ear Chickweed (*Cerastium*), found in almost any wild spot, has its capsule tilted laterally at the tip, and opens by ten minute teeth. The seeds rest safely until a high wind comes along, when they are shaken out and carried away. This places it in a superior position to that of ordinary Chickweed (*Stellaria media*), which opens all the way down, the seeds falling on the adjacent ground.

The beautiful Red Campion, with its bottle-shaped capsule, also opens by ten teeth, and is admirably fitted for wind-dispersion. The Catchfly of our corn fields, Pink, and Primrose, open in similar fashion.

Another method is that of pores, or tiny circular holes near the top, through which the seeds escape under the action of wind after the plant has opened its "windows." These may be seen in Mignonette, Snapdragon, Toad Flax, Canterbury Bell, and notably in Poppy, where the overhanging edges of the circle of stigmas protect the openings. The pores themselves are said to close in wet weather. This I have not, as yet, ascertained to be the fact myself. In those Canterbury Bells whose fruits are pendent, the capsules open at the base, which is of course uppermost in these cases. We see, therefore, that it is a useful provision that ensures the capsules opening above, so that the seeds may remain prisoners until the wind acts on their capsules, and afterwards on themselves, to carry them far afield.

In Pimpernel and Plantain the capsules open by a circular line entirely round the fruit, the top part coming off like a pill-box cover. Here, again, the wind can act when the seeds are ready for it.—H. W. S. WORSLEY BENISON, F.L.S. (in the *Journal of Microscopy*).

(To be continued)

RED SPIDER ON VINES.

Of all the troubles which a Grape grower is heir to, none is so bad as an attack of red spider on the Vine foliage. Nothing that I am acquainted with prevents the berries colouring so effectively as having the foliage covered with red spider. Perhaps Black Hamburgh is the variety most subject to spider of all the varieties grown, for the reason, I presume, that this has more fire heat through early forcing than all other sorts together. I never yet saw Grapes of this variety colour well when the leaves were badly infested at the time the berries were commencing to colour, and that is the period when this pest most often appears.

Many remedies are recommended for its eradication, such as painting the hot-water pipes with sulphur and making them hot, which is not the least use as far as my experience goes. I think this method of applying sulphur is bad in another way. Without much care is used in thoroughly cleaning it off the pipes the following season when the

Vines are in bloom, the fumes arising from the pipes when hot sometimes cause the berries to be rusted, which is a serious defect. I have seen this occur many times. Then, again, sponging the leaves with soapy water, tobacco water, and many other concoctions, but I never yet found any of these effective, not half so much as I have been led to believe. The best of all remedies is to dust the affected leaves upon the first appearance of red spider with dry sulphur, that of a brown colour is best as not being so conspicuous as the ordinary colour. With the use of a distributor the leaves can be covered with the sulphur without disfiguring the bunches.—S.

COMMERCIAL FLORICULTURE AND AMERICA.

[Read before the Massachusetts Horticultural Society by Mr. W. J. Stewart of Boston.]

(Continued from page 190.)

Most of us can remember the time when the whole cut flower trade of Boston probably would not have sufficed to keep one of our modern flower shops going. About the only flowers which could be bought in this city were the few stiffly made bouquets that were brought to town every morning, and offered for sale in the windows of some provision dealer or druggist.

What a contrast with the condition of the flower business of to-day! There are plenty of men engaged in it who in general intelligence, education, and refinement are the equals of those in any other line of trade. It is rapidly becoming a business of vast importance; with a large amount of money invested, with its wholesale, commission, and supply dealers, importers, jobbers, and retailers. It is no longer in the experimental stage, and cannot be successfully conducted at random or by guesswork. Competition and increased investments of capital have brought prices down as low as possible, and the man who does not manage his business carefully and systematically stands but a poor chance to succeed. Foresight, energy, and brains are what tell in the flower trade of to-day; and there is room in it yet for more men who are blessed with these requisites. The man who raises the best flowers in the market of any variety is always pretty sure of good sales at good prices. With such perishable articles, which cannot be produced at will, there will always occur seasons of glut, and at such times it is the man that offers the inferior stock who must go to the wall first.

The tendency of those engaged in growing flowers for the market nowadays is towards specialties. It is certainly better for a man to grow two or three things well and gain a reputation for those specialties, than to produce a little of everything indifferently. Most Rose growers now limit themselves to a few varieties, which for one reason or another they regard as the most profitable, and the best success is attained where each variety has a separate house. The number of varieties of Roses which may be considered as staple, since they are quoted at wholesale in most of the large markets in this country, is about twenty-five, as follows—Bon Silene, Safrano, Isabella Sprunt, Niphetos, Perle des Jardins, Sunset, Papa Gontier, Souvenir d'un Ami, Madame Cusin, Souvenir de Malmaison, Maréchal Niel, Cornelia Cook, William Francis Bennett, Pierre Guillot, Bride, Catherine Mermet, American Beauty, Général Jacqueminot, La France, Baroness Rothschild, Madame Gabriel Luizet, Magna Charta, Anna de Diesbach, and Duke of Connaught.

Other varieties which are grown for the market, but less generally, are Douglas, Duchess of Edinburgh, Yellow Tea, Royal Tea, Lamarque, Reine Marie Henriette, Climbing Devonensis, Boule de Neige, and an assortment of Hybrid Perpetuals, which are forced for winter consumption. The most desirable points in a market Rose are continuous and abundant blooming, long stems bearing single buds, and robust foliage, with fragrance, clear colour, and good keeping qualities in the flower.

Quite a large proportion of Roses grown about Boston are shipped to other points in New England, Canada, and the West. The shipping trade has grown to be a very important item, and is the outlet through which our surplus finds its way, and which keeps prices up so as to afford a fair remuneration. There is no doubt that during the greater portion of the year there are more Roses grown about Boston than it would be possible to consume here, and if the shipping trade were to cease we should be swamped, and prices would at once fall far below the cost of production, bringing ruin to many.

The popularity of the Rose seems not to diminish, and it probably will not as long as the demand for novelties is supplied by new varieties. Every year brings forth fresh candidates for popular favour, most of them from the other side of the water, but the proportion of really successful ones is small as compared with the number sent out. The conditions under which a Rose is forced for market in this country are so different from those under which it is raised and grown abroad that many Roses of European origin, whose appearance has at first given great promise, have proved utter failures, causing much financial sorrow to those who invested in them.

The Carnation has taken a fresh hold upon popular fancy within two or three years, and deservedly so, for the new kinds which have been introduced recently are in many respects great improvements upon the old varieties. To be valuable now, a Carnation must produce its flowers on single stems, so that they can be cut long. The flowers must be distinct in colour, large and full in form, and not inclined to burst at the calyx. The Violet is a popular flower the world over. The only variety which is generally saleable here is the Marie Louise, and this is subject to a disease which has baffled the most experienced Violet growers and forced many to give up its culture. The result is that those whose plants have escaped the scourge have reaped a profitable

return during the past two years. It is a singular fact that in Philadelphia single Violets are the most popular, while here they cannot be sold.

After Roses, Carnations, and Violets, the flowers most extensively grown for the market are those produced from bulbs and tubers, such as Lily of the Valley, Roman Hyacinths, Tulips, Daffodils, and Lilies of several kinds. Dutch Hyacinths, which were so much sought after formerly, are now positively unsaleable. Who would have believed it possible a few years ago that Lilies of the Valley could be produced the whole year round? Yet it is true that there is not a day in the year when these flowers cannot be supplied in quantity. Other flowers which may be considered as staple, being regularly quoted in the wholesale market, are Nareissi of several kinds, Freesias, Bouvardias, Mignonette, Callas, Camellias, Myosotis, Lilacs, Pansies, Smilax, and Ferns; also some kinds whose sale is limited to certain seasons, such as Sweet Peas, Asters, Chrysanthemums, Gladioli, &c.

The difference between the varieties called for here, and in England, is seen by consulting the prices current as published in the English periodicals. There we see quoted Tea Coloured, Red French, and Safrano Roses, with Tropeolums, Primulas, Poinsettias, Jasmine, Gardenias, Abutilons, Cornflowers, Pyrethrums, Pelargoniums, &c. So much for fashion. A wholesale dealer who should offer that list as his stock in trade would starve here.

The extent of the cut flower and kindred industries is much greater than is generally imagined. I have corresponded with such gentlemen as Peter Henderson, John N. May, August Rolker & Sons, W. S. Allen, and J. C. Vaughan, with a view of compiling some estimates which would be approximately reliable; but the figures received vary so much that it is difficult to arrive at a satisfactory conclusion. The importation of Lily of the Valley roots amounts to several millions annually; the growing of these roots for this market being quite an industry abroad. The consumption of cut Tulips alone certainly amounts to many thousands daily during the winter season, and the number of Roman Hyacinths grown is simply enormous. Cut flowers amounting at wholesale prices to one million dollars in value pass through the hands of commission dealers annually, and the amount sold by growers for the market outside of the commission dealers must be as large, if not larger.

From fifteen to twenty thousand dollars is invested annually in plants of new varieties of Roses. Mr. Thorpe estimates that there are 630 acres of ground covered with glass in this country, about one-half of which is devoted to the growing of plants and one-half to the production of cut flowers. There are probably not less than 15,000 individuals engaged in growing plants (for sale or for cut flowers) and in florists' stores.

Not less than fifty million plants are sold annually, and the importation of bulbs and plants must amount to nearly, if not quite, half a million dollars in value. Tuberous bulbs, which we formerly imported, we now export in large quantities; and the exportation of Pampas Grass has also grown to be quite a large business. One and a half millions of plumes is probably a low estimate.

But these figures give little idea of the amount of business or number of people directly or indirectly dependent upon the cut flower trade. Consider the material used in constructing greenhouses, such as glass, iron pipe and fittings, hot water boilers and steam apparatus; the labour employed and the money invested in the manufacture of plain and fancy flower pots, rubber hose, fertilisers, insect exterminators, and horticultural tools of all kinds; also the capital invested and the number of people employed in the making of ornamental baskets; and the value of baskets of foreign manufacture, of Wheat, immortelles, &c., which are imported annually. One estimate places the value of coal annually consumed at nearly four hundred thousand dollars. Tons of iron are made into wire and wire designs for florists' use; many thousands of pounds of tin-foil, also cords of wood (in the form of tooth-picks for stemming flowers, and of plant stakes), are items of considerable account; while the rents paid for stores and the money paid in wages to help of both sexes must amount to a large sum. Enormous quantities of Moss, wild Ferns, ground Pine, Laurel branches, &c., are gathered in the woods every year, this one industry giving continuous employment to many people in the country. The Boston market alone consumes annually two million wild Ferns, two thousand barrels of Moss, 4 to 5 tons of ground Pine, and twenty thousand yards of Laurel festoons. These figures are for regular florists' demands, and do not take into consideration the Christmas trade in greens, which of course is very large.

We must not forget the large sums spent in illustrated catalogues, many of which are really works of art, and in postage paid on the same; nor should we overlook the educating influence of the illustrations in such publications, which are generally true to nature, with the result that the average flower painter or engraver of to-day knows better than to sketch Lilies with five petals; and needs not be told that Lilies of the Valley do not branch or that Morning Glories do not bear tendrils. The general knowledge of varieties in flowers and of their habits and characteristics, which a florist finds nowadays among his customers, is very gratifying and is significant, showing as it does the educating influence which has been at work—a result which is due largely to the enterprise and liberality of the commercial florists, who have placed the choicest productions of Nature's handiwork within the reach of everybody, no matter how poor.

What a wealth of beauty is displayed in the florists' windows to-day! The old stories we used to read in our younger days of the poor city

children who had never seen a green field, a Rose, or a Dandelion are no longer true. The situation has indeed changed; and Rose buds, Violets, Sweet Peas, and Daffodils are now as familiar to the eyes of the children of the street as they ever appeared to the most fortunate of their country cousins.

(To be continued.)

CABBAGES—A CRITIQUE.

I WAS pleased to notice that "A Yorkshire Cabbage Grower," page 163, has understood part of what I wrote on "Cabbages for the Spring," page 90. He says "A Kitchen Gardener" "has nothing to learn in the art of laudation on the one hand, and condemnation on the other." That is so. Let me tell him why. I have spent so much of my own valuable time and my employer's money during the last twenty years or so in testing new vegetables, and found so many of them utterly worthless, that I have long since ceased to take any middle half-hearted course of dealing with them, letting them have it right and left, that no one can misunderstand my meaning. I have it on the authority of "A Yorkshire Cabbage Grower" that I succeeded in this, and let me ask your readers if they do not approve of a plain "Yes" or "No." I do, and I like it in others, but I must say I do not approve of beating about the bush and trying to gain admission by the back door, and I fear I have caught "A Yorkshire Cabbage Grower" attempting this. I wrote of Cabbage for spring. He objects to my discarding Early York amongst varieties most suitable for growing to come in at that time, and says there is no variety in existence to equal it for sowing in spring to come in for autumn use. I never disputed that, but I am no autumn Cabbage eater. Very few are, and surely those who do grow them at that time can find better varieties than the Early York, which is now rarely grown in any garden. If Ellam's Early is so good and so much more valuable than all others in the spring, as "A Yorkshire Cabbage Grower" says it is, why should it not be equally good in autumn, and how is the Early York preferred to it? There is a mystery here which the words of your correspondent do not explain. As to the time of sowing, to which so much exception is taken, the 10th of July, proved too early year after year in our case, so it has in scores of others, and those who have tested the matter carefully prefer having medium sized and sound plants from the last week of July sowing to the very early ones which lose so much in bolting. "A Yorkshire Cabbage Grower" need not think I am romancing. I have had Cabbages as large as any one has in November and December, but their condition in March and April, especially after passing through a severe winter, did not warrant me in adopting them, or advise others to do so.

I have re-read the remarks, page 90, which have roused the ire of "A Yorkshire Cabbage Grower;" they explain themselves, and I have nothing to withdraw.—A KITCHEN GARDENER.

BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.

EXCURSION TO READING AND HECKFIELD PLACE.

A MOST enjoyable event in connection with the above Association took place on Monday, August 27th, when a party consisting of about seventy members left Birmingham at 5.40 in the morning, arriving at 8.30, and were met at the station by members of the firm of Messrs. Sutton & Sons, who had provided carriages to convey the party to their extensive trial grounds. After a drive over the greater portion of this very interesting place, we alighted and made a close inspection of the excellent varieties of flowers and vegetables for which this firm has so long been celebrated, and the many and oft withdrawals of the pocket-book and peneils afforded proof that the members had found something worth recording. Having inspected as far as time would permit (as we had a very heavy day's programme before us), and the members had secured all the information they required, we were then conveyed to the London Road Nursery, where Cyclamens, Begonias, Gloxinias, Primulas, &c., are grown extensively for seed, and the first thing to rivet the attention here was the wonderful display of Tuberous Begonias grown from seed sown last January. Amongst them were to be found all the colours known to this class of plants, the flowers being of great size and substance, also more erect than usual, which is a great desideratum. Cyclamens grown from seed sown last November are wonderful examples of high culture, their short sturdy habit and the breadth and substance of the foliage being a sure indication of the excellence of the strain and the close and skilful attention bestowed on the plants. Gloxinias were fading, but there was no mistaking the excellence of the plants and strain. Having exhausted the time set apart for this nursery, we were then conveyed to the extensive seed stores, a close inspection revealing a faultless system of management. A goodly quantity of bulbs had arrived, and were being unpacked, cleaned, and labelled ready for the "season." After passing through the establishment we were conducted to the lecture hall, where a sumptuous dinner was provided. Mr. Martin John Sutton presided, and was supported by Mr. L. Sutton, Mr. W. Wildsmith, and Mr. W. B. Latham (Chairman of our Association). The Chairman briefly addressed the visitors, and expressed the great pleasure it gave them to meet and entertain such a representation of the gardeners of Birmingham, and hoped that although it was our first visit it would not be the last. He closed his remarks by proposing "The Health of the Birmingham Gar-

deners' Association," to which Messrs. Latham, Wildsmith, and Jones responded.

We next proceeded to Heckfield Place, a drive of about nine miles. A hearty welcome awaited us, not only from Mr. Wildsmith, but likewise from his generous employer, Viscount Eversley and Miss Lefevre; the latter came out on the terrace and seemed extremely pleased to see the party enjoying their visit. Mr. Wildsmith conducted us round the place, being extremely anxious that nothing of interest should escape our notice. Having viewed the whole of the garden, houses, and pleasure grounds, and tried in vain to find a weak point in Mr. Wildsmith's management, we retired to a marquee where tea had been provided by Mrs. Wildsmith. Mr. Wildsmith was asked to convey a hearty vote of thanks to Viscount Eversley and Miss Lefevre for their kindness in allowing us to view their beautiful gardens, and a similar proposal to Mr. and Mrs. Wildsmith was carried with acclamation. The members were delighted with the visit, and freely expressed the opinion that a more charming or better kept place it would be impossible to find. Reading was reached in time for the 7.30 fast train for Birmingham, where we arrived at 10.5 P.M.—J. H.

EVENTS OF THE WEEK.—September 6th, Royal Caledonian Horticultural Society, Autumn Exhibition (second day). On Friday and Saturday, September 7th and 8th next, the Fruit and Dahlia Shows will be held at the Crystal Palace, Sydenham. At the same place there will also be a Conference of Fruit Growers at 3 P.M. on Friday and 2 P.M. on Saturday. The Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall on Tuesday the 11th inst. On Wednesday the 12th inst. the National Chrysanthemum Society will hold an Exhibition of early-flowering Chrysanthemums and Dahlias in the Royal Aquarium, Westminster. The Brighton Show is fixed for that and the following day, as also is an Exhibition at Glasgow. Bulb sales by Mr. J. C. Stevens at 38, King Street, Covent Garden, every Monday, Wednesday, and Saturday.

— AT the next meeting of the Fruit and Floral Committees of the ROYAL HORTICULTURAL SOCIETY in the hall at Westminster, on the 11th inst., Dahlias, Begonias, Asters, with fruit of various kinds, are expected to be well represented.

— WE are informed that by the permission of Lady Bateman a Fête was held in OAKLEY PARK GARDEN, SCOLE, SUFFOLK, last week, for the benefit of the Gardeners' Royal Benevolent Institution, with the satisfactory result that though the weather was unfavourable Mr. A. McMillan, the gardener, has been able to forward to Mr. Cutler £18 17s. 6d. as the profits of the fête.

— **GARDENERS' ORPHAN FUND.**—We have the pleasure to announce that at the flower show held at Heckfield Place, on August 28th, Mr. Wildsmith, the Local Secretary for that district, collected the sum of £5 from three boxes.

— WE are informed that the wife of MR. JOHN ROBERTS, who has endured a long and painful illness with great patience and fortitude, died at Gunnersbury Park Gardens on Saturday last.

— **SHREWSBURY SHOW.**—Amongst the miscellaneous exhibits at this Show, we omitted to mention that Messrs. W. & J. Birkenhead, Sale, Manchester, had a collection of Ferns, remarkable for number of varieties and good health.

— **CHRYSANTHEMUM SHOW FIXTURES.**—The annual Exhibition of the Pembrokehire Chrysanthemum Society will take place on November 9th and 10th, and that of the Winchester Horticultural Society on November 13th and 14th.

— **GARDENING APPOINTMENTS.**—Mr. Charles Sutton, who has been foreman at Willey Park Garden, Broseley, for the past four years, has succeeded Mr. Gray as head gardener to Earl Stanhope, Chevening Park, Sevenoaks, Kent. Mr. C. Sawyer, for the past four and a half years principal foreman at Cricket St. Thomas, Chard, Somerset, has been engaged as gardener to the Marquis of Hertford, Ragley Hall, Alcester, Warwick.

— AT a FRUIT CONFERENCE held at St. Albans on Tuesday evening, Mr. Sampson Morgan, amongst other things, is reported to have said—"Freehold land in plots suitable for the culture of early produce and choice fruit could be had at an average rate of £20 per acre, or at an annual rental of £1. Upon each 2-acre plot might be erected a cottage in connection with which he would give to each labourer 50 feet of glass house, or 100 feet of frames, or an extra quantity of fruit trees instead. From each plot a steady and industrious man could obtain a permanent living, sufficient for himself and family. The cost for the 2 acres, cottage, glass erections, 200 special fruit trees, seeds, plants, &c., would be £125, which let to return 5 per cent. on the investment would mean £6 5s. per annum. Thus for 2s. 6d. each per week a worthy labourer could secure a perfect little homestead from which could be raised poultry, eggs, fresh and preserved vegetables, fruit juices, essences, and hardy fruit, as well as choice early produce of every kind." We doubt if all our readers are equally sanguine that ordinary labourers could make for themselves such an arcadia as suggested—at least, in rural districts remote from large centres of population, but shall be glad to hear what practical cultivators have to say on the subject. Mr. H. Hobday advocated a system of culture, giving a tenant "freedom to plant with full power to sell or remove not only fruit trees, but every other kind of garden produce." Mr. W. F. Emptage considered the "laying down of land under grass had done more to bring about agricultural depression than any foreign competitor; recommended planting the Keswick Codlin and Blenheim Orange Apples, and was of opinion that Black Hamburgh Grapes under glass without fire heat could be made to pay at 4d. per lb."

— MR. T. S. WARE, Hale Farm Nurseries, Tottenham, sends us a few flowers of ANNUAL POPPIES of what are termed the "Shirley" type. They are derived from Papaver Rhæas, and, as we have frequently noted, are extremely pretty, white, blush, pink, rose, and crimson, often edged with white, very delicate and fugacious, but presenting some charming colours.

— THE raiser writes, "I send you a few blooms of CARNATION EDWIN MOLYNEUX raised last year from seed, and certificated last week at Salisbury. It is a capital border variety, flowering profusely, as many as fifty to sixty flowers on a plant, which are from layers last autumn. I have not seen a single flower which has been at all split in the calyx. In a cut state it is effective, particularly when arranged in a mass. The enclosed flowers are small, as it is getting near the end of the season. The flower stalks are stout, very erect, thus rendering it a first-rate border plant. Unfortunately it has no fragrance." The variety is useful, and for borders very free and strong, the flowers closely streaked with bright red on a yellow ground. We have grown one exactly similar in character for several years.

— **GARDEN AND FARM INSECTS.**—"Entomologist" writes, "The season has indeed been unfavourable for gardeners, but in the range of my inquiries this fact has come out, that, although during the early summer caterpillars were very numerous, since the heavy rains and cold winds there has been a diminution of insect foes of all sorts. There has also been a scarcity of friendly insects, "lady-birds" for example; the Coccinellæ group have been few as yet in this part of Kent. This may account for the abundance of aphids on the Hops; that unfortunate plant has suffered much from this and other insect enemies. Miss Ormerod has noted that in the Midlands the Wheat crops have upon some fields been greatly damaged by the aphid granaria, perhaps others also. In going through one field of Wheat about a month ago I found examples of a sawfly larva in the ears, but I regret that I did not identify the species."

— **NATIONAL CHRYSANTHEMUM SOCIETY.**—A meeting of the Committee took place at Anderton's Hotel, Fleet Street, E.C., on Monday, the 3rd inst., Mr. E. Sanderson, President, in the chair, there being a large attendance of members. The minutes of the last meeting having been confirmed, an interesting communication from the Secretary of the Victorian Horticultural Association, Melbourne, was read, and the Secretary, Mr. W. Holmes, said that a deputation from the Association had subsequently waited upon him for information as to the working of the Society in this country, and that a very pleasant meeting had resulted. The following Societies were admitted into affiliation:—The Barnsley, Hampstead, Isle of Sheppey, Stroud, and Truro Chrysanthemum. Mr. G. T. Miles of Wycombe Abbey Gardens, was appointed

one of the judges of fruit and vegetables at the November shows at the Royal Aquarium in the place of the late Mr. John Woodbridge; and this being the first meeting of the Committee since his decease, a vote of condolence with his family was unanimously passed. The Secretary reported that representatives of the National Chrysanthemum Society had met representatives of the Sheffield and West Riding Chrysanthemum Society to arrange the preliminaries of the Provincial Show on November 16th and 17th; that this had been done in the most satisfactory manner, and there was every reason to believe it would prove highly successful. Two new Fellows and forty-eight new members were duly elected, bringing the number of members up to 510. The Secretary, regretting the unavoidable absence of the members of the Catalogue Revision Committee, said the publication of the revised catalogue was in a very forward state, and he hoped copies would be in circulation by the Show on September 12th. The schedule of prizes for the first Provincial Show at Sheffield on November 16th was laid upon the table; also that of the Barnsley Chrysanthemum Society. The proceedings closed with a cordial vote of thanks to the Chairman.

— SHOW OFFICIALS EXHIBITING.—We have received the following note, which we publish:—"On August 30th there was held at a noted seaside town in Norfolk the annual Exhibition of plants, flowers and vegetables, and as dissatisfaction was shown by exhibitors at some of the awards I shall be glad in your next issue of your opinion on the following facts:—The cut-flower tent was under the entire control of the largest exhibitor, a local florist, who went round with the judges when they (or he) were making the awards. In this tent he and a member of his family took some fourteen prizes, and in the pot-plant tent some seven more. The judges in the two tents I understood were gardeners in the neighbourhood, and I ask if you consider this arrangement one likely to have given entire satisfaction to other exhibitors, and especially to amateurs from a distance."

[Although the prizes in question may have been properly awarded it is scarcely possible that the arrangement in question could give satisfaction to the general body of exhibitors; and "amateurs from a distance" could not repose confidence in any society which allowed an exhibitor to have the entire control of a show and assist the judges in their duties.]

— WAKEFIELD PAXTON SOCIETY.—The following is the programme of meetings for the third quarter, session 1888. Meetings are held at the Society's rooms, "Saw Hotel," Westgate, each Saturday evening, commencing at 8 P.M. September 1st, the Carnation and Picotee Exhibition; essay by Mr. G. Armitage, Morley. September 8th, "A Few Hints on Watering," Mr. L. Twigge. September 15th, "The Pea;" exhibition and discussion. September 22nd, "Habits of Plants," Mr. S. Ballinger, Barnsley. September 29th, "Reminiscences of a Yorkshire Naturalist," Mr. C. Rigg; (sale of papers). October 6th, "Air Pollution as Affecting Plant Life," contributed. October 13th, "The Potato" (with specimens), Mr. W. L. Skinner. October 20th, "Fungi and Fairy Rings," Mr. W. Hudson. October 27th, "Curiosities of Plant Life," Mr. J. Haigh, Sheffield; (sale of papers). November 3rd, "The Thrush Family as Seed Distributors," Mr. G. Parkin. November 10th, "Germs and the Germ Theory," Mr. H. Crowther, Manchester. November 17th, "Insects Parasitical on Plants," Mr. West, Rotherham. November 24th, Chrysanthemum Exhibition; essay, "A Review of New Varieties," Mr. T. Garnett. At the ordinary meeting of the Society held on Saturday evening last Mr. J. G. Brown presided, and Mr. A. Goldthorpe occupied the vice-chair. Mr. W. Daniels, gardener to Mrs. Hague Cook, Hall Croft, Mirfield, was the essayist, the subject being Lilliums. Mr. Daniels bases his practice on careful study of the plant requirements, starting with the structure of the bulbs and the annual character of the rootlets. A useful lesson was conveyed of the necessity of understanding these peculiar characteristics, on which generally speaking some amount of misconception has prevailed. Half a dozen stands of magnificent flowers of the *Lilium lanceifolium* type were exhibited by the essayist. The usual vote of thanks was conveyed to Mr. Daniels after a long and animated discussion.

A SAD CASE.

YOUR kind insertion of the letter in last week's issue has been the means of bringing several donations to the fund for the relief of the late Joseph Richardson. The sufferer died on Tuesday last, and was laid to rest in Calverton Churchyard on Friday. He desired me to express his gratitude to you for your prompt donation and assistance to

him in his last moments. May I ask you to mention his death in your columns? Any further assistance that may be obtained will be handed to his widow, who is left with six children totally unprovided for.—E. STEWARD, 2, Exchange Row, Nottingham.

[This adds one more to the many cases that prove the desirability of strengthening the Gardeners' Orphan Fund, in order that permanent assistance can be rendered to necessitous applicants.]

DISAS.

THOUGH slightly puzzling to some cultivators *Disa grandiflora* is a favourite in the majority of Orchid collections, and it is

FIG. 24.—DISA LACERA.

more frequently seen in good condition than was the case a few years ago, thanks probably to the ready manner in which successful growers have communicated the results of their experience. But there are numbers of other Disas which, if not possessing such large or brilliantly coloured flowers as *D. grandiflora*, are yet attractive in no ordinary degree, and amply deserving of the few attentions they claim. The Cape of Good Hope is especially rich in terrestrial Orchids, and has been described as their head quarters in the southern hemisphere. Of Disas alone 100 species are known, and some of these were described by Thunberg in his "Flora Capensis." Amongst them are the subjects of the two illustrations, *Disa lacera* (fig. 24) and *Disa racemosa* (fig. 25), both of which have recently flowered, been exhibited at the Royal

Horticultural Society's meetings and certificated by the Floral Committee.

DISA LACERA.

From Mr. A. H. Smec's garden at Carshalton a plant of a "blue Disa" was sent to the R.H.S. meeting on August 28th, when a botanic certificate was awarded for it. The flowers are small, of a bluish purple hue, and are produced on a slender scape without leaves, as shown in our illustration. Alone it is not a very conspicuous plant, but associated with others the flowers have a good appearance, owing to their distinct colour, though this is by no means the brilliant blue some might be led to expect from glowing descriptions given in past times of the blue Disas at the Cape. It has, no doubt, been carefully determined, but several reliable authors mention *D. lacera* as having white or whitish flowers, and it so appears in Thunberg's "Flora Capensis." As recently noticed in this Journal, Mr. Smee grows his Disas out of doors on a lattice suspended over a stream of water and shaded by trees.

DISA RACEMOSA (D. SECUNDA).

With regard to *D. racemosa*, it is somewhat strange that although known to botanists for so many years it should not have been introduced to cultivation, or at least flowered, until last year. Mr. J. O'Brien of Harrow-on-the-Hill introduced this with several other Cape Disas and rare terrestrial Orchids, and flowers were produced for the first time in October and November 1887. In May of the present year a strong plant was also flowered in the Royal Gardens, Kew, and when exhibited at Westminster on May 22nd it attracted much notice from the orchidists and other visitors, a well merited certificate being awarded for the plant. The flowers are produced in slightly one-sided racemes, to which character the synonym *D. secunda* is due, and are distinguished by their bright rosy crimson colour, a very pleasing tint in contrast with white or light-coloured flowers. It is not a difficult plant to grow, but needs a watchful guardian, and in an ordinary cool house with *Disa grandiflora*, out of doors in a sheltered position, or in a frame, it has been found equally healthy and satisfactory.

SPATHOGLOTTIS VIEILLARDI (S. AUGUSTORUM).

A BEAUTIFUL Orchid described by Reichenbach as *S. Augustorum*, exhibited by Sir Trevor Lawrence at a meeting of the Royal Horticultural Society on July 13th, 1886, and certificated by the Floral Committee, has been found to be identical with a plant previously described by the same author, and Sir Joseph Hooker gives the following history of the plant, accompanied by an excellent coloured plate, in the "Botanical Magazine" for the current month:—

"*Spathoglottis Vieillardii* was first made known by Dr. Reichenbach's description published in the 'Linnæa' in 1877, taken from specimens collected between 1861 and 1867 in New Caledonia by the botanist whose services and name it deservedly commemorates. It had, however, been previously collected (in 1853) in the Isle of Pines (one of the same group) by Mr. MacGillivray, naturalist to Captain Denham's voyage to the Pacific, specimens from which source are in the Kew Herbarium. On the *Spathoglottis Augustorum* flowering at Kew Mr. N. E. Brown recognised its identity with the previously published *S. Vieillardii*, and I am unable to detect any difference between the two plants. It is to be observed, however, that the Straits of Sunda, from whence *S. Augustorum* was sent by the two collectors, Auguste Linden and Auguste De Ronne, are very far from the New Caledonia Archipelago, and the presence of the same terrestrial Orchid in such distant localities was hardly to have been anticipated. Apparently the same species has been collected in the Banda Islands by Mr. Moseley when on the 'Challenge' Expedition in 1875. Mr. Linden states that the figure in 'Lindenia' represents a very poorly developed state of the plant, but except that the leaves are shorter and flowers a third larger it accords in development with that here given, and with the Herbarium specimens. In both the raceme has only commenced flowering, for as flowering advances the raceme lengthens, and the lower part from which the flowers have fallen is clothed with the persistent deflexed imbricating bracts.

"The specimen here figured was purchased in 1887 in Messrs. Protheroe & Morris' auction room. Mr. Watson informs me that it is the strongest and best grower of all the cultivated species of *Spathoglottis*. It flowered in the tropical Orchid house at Kew in September of last year.

"DESCRIPTION.—Pseudo-bulbs 2 inches long, ovoid, at length nearly naked. Leaves 1 to 2 feet long by 2 to 2½ broad, sessile, spreading and recurved, elongate-lanceolate, gradually acuminate, closely costate and plicate. Scape from the base of the pseudo-bulb, 12 to 18 inches high, robust, terete, with three or four distant short appressed subacute herbaceous sheaths. Raceme at first corymbiform, lengthening to 6 inches; bracts 1 inch long,

herbaceous, broadly ovate, subacute, concave; pedicels and ovary half to 1½ inch long, puberulous. Perianth 2 inches

FIG. 25.—DISA RACEMOSA.

in diameter. Sepals and petals very pale lilac or nearly white, ovate-oblong, subacute. Lip about as long as the sepals; lateral lobes small, erect, and incurved, subtruncate, orange-brown, with

two large tumid orange calli speckled with red occupying the disk between them, and each callus produced at the base into a short spreading lobule; midlobe small, lilac, on a long slender stipes variable in form from trapeziform with rounded sides and an obtuse or acute tip, to very broadly obovate. Column slender, incurved. Pollinia eight, with slender caudicles."

In this *Journal* for September 23rd, 1886, page 277, an illustration was given of the Burford Lodge specimen under the name of *S. Augustorum*.

REVIEW OF BOOK.

Treatise on the Cultivation of the Pansy. By ALEX. LISTER. Paisley: Alexander Gardner, 1888.

THIS modest production of fifty-six small pages contains a variety of interesting and useful information respecting the Pansy, and possesses especial value as the work of a practical cultivator who has distinguished himself in reference to these popular flowers. After an introductory note, Mr. Lister devotes chapters to "Propagation from Seed," "Propagation from Cuttings," "Culture," "Gathering and Preparing Blooms for Competition and Exhibition," "Mildew," "Properties of Show Pansies" and "Fancy Pansies," all of which are treated concisely and clearly.

We quote the remarks on propagation from cuttings as seasonable information, and a good indication of the author's method:—In order to perpetuate and increase any new and good variety of Pansy, there are only two ways—either to propagate from cuttings or by division of the root. The latter method is rather a clumsy way, and for many other reasons objectionable; in some cases it may be resorted to, but to those who intend growing for competition cuttings are by far to be preferred. As I have recommended in propagating from seed, so also in propagating from cuttings—propagate only from the best and healthiest plants. Although cuttings can be struck from unhealthy plants, it will save a good deal of annoyance and disappointment if such plants are passed by when cuttings are being gathered. In selecting them choose short stumpy cuttings as near to the root as possible. Of course, when a variety is scarce one has to take all sorts of cuttings which are to be had, so as to make the most of the plant, but where such is not the case it is more satisfactory in every way to choose the best; they strike more easily, are more uniform in the propagating bed when put in, stand the winter better, grow more vigorously when planted out, and, as a matter of course, everything else being equal, yield better blooms.

September is the best month in which to put in cuttings. They can be put in at any time during the season, but by putting them in before this time they will grow a good deal, so that by the time the season arrives for planting out they will be rather leggy. By propagating in September the cuttings have plenty of time to make as many roots as will be necessary for their healthy existence, and by the following March the plants will be short and stubby, and just be in the proper condition to begin the operations of the season with every prospect of success.

The best place to put in Pansy cuttings and to preserve them through the winter is a cold frame. The best position is the one having a northerly exposure at the back of, but not too close to, a wall, in which to place the frame, as in the early months of the year when frosty weather prevails they are not so much exposed to the action of the sun's rays, which is very injurious to all plants of such a soft texture as the Pansy. In preparing the ground, set apart from the frame, the soil should be dug at least spade deep, and having placed the frame upon it, prepare as much soil—consisting of equal parts of good loam, leaf mould, rotten dung, and fine sand—as will cover the surface to the depth of 6 inches. Having distributed and levelled this over the frame, take the same soil, adding to it another part of fine sand, and pass it through a half-inch riddle; spread this again equally over the surface to a depth of 4 inches, and level it so that in no part of it shall the surface be more than 6 inches from the glass when the sash is put on. Press the soil firmly with a board or the back of a spade, give it a watering with a rose, let it stand for an hour, after which the operation of dibbling in the cuttings may be proceeded with. Assuming that such cuttings as I have indicated have been gathered—that is, nice short healthy cuttings having not less than four or five joints, with a good sharp knife take off the leaves from two of the joints, cutting clean and close to the stem without injuring it, then cut it clean across immediately below the lowest joint, when it is ready for dibbling in.

After having prepared as many cuttings as may be thought necessary for the time being, and having labels prepared and ready on which to write the names of each variety, begin by making a line, at about 2 inches from the left hand end of the frame, and having stuck in a label with the name of the variety to be put in first, a small dibber of about the thickness of one's finger, and 6 or 7 inches in length is used. With this a hole is made, the cutting inserted and well firmed by again using the dibber at a little distance from the side of the cutting. Great care must be taken that the cutting be properly firmed, that it be equally pressed all over that part of the stem which is underground, and that it be not subjected to the operation of hanging, that is of firming the cutting at the neck or at the surface, and leaving it open and loose at the root end. This is a point of the utmost importance, the neglect of which is often attended with disaster, of which I myself have had bitter experience. A few seasons ago I gathered and dressed my cuttings myself, and to one of my assistants, in whom, at the time, I had every

confidence, I entrusted the dibbling of them in. As time went on, they did not seem to make any progress, I could not conceive what was the matter, and as I could not help myself, for I had put in every cutting I could gather, I had just to wait patiently and watch the result. As the spring came they began to drop off altogether, so that out of about 20,000 cuttings I was not able to lift more than 5000 plants. This was a lesson which I am not soon likely to forget, for in addition to my own loss from a pecuniary point of view, I was compelled to disappoint many of my best customers.

Having finished the first row it will be noticed that a hole is left by the dibber alongside of each cutting, this is filled in by having close at hand a portion of dry fine sand, levelling it with the hand. The second row is then proceeded with 3 inches apart from the first. A very good plan, and one which I adopt, is to have a piece of board 3 inches broad and its length nearly the breadth of the frame. As each row is finished, to lay it on its flat on a line, and close to the last row of cuttings put in, press slightly, then turn it on its edge and press it, so as to leave a mark, which forms the line in which to insert the cuttings. By this means a nice evenly surface is left behind, the rows are sure to be at equal distances, and when the frame is full it gives the whole a neat finish. After giving a good watering with a fine rose, put on the sash, keep it closed and shaded from the sun, so that the cuttings may not be allowed to flag. In about ten days or a fortnight air may be admitted to them by tilting up the sash, and shading may shortly be dispensed with altogether, as the more light and air they have the better, and with the exception of hard frost the sash should never be closed upon them day nor night. By adopting this course the plants are not drawn up, neither are they weakened, and when hard weather does come they are more able to stand it than if they had been coddled too much. With the exception of keeping them clean, and of course protecting them from severe frost by closing the sash and throwing a mat over it at night, they will require very little attention during the winter months and on till the time of planting out. A fortnight or three weeks before this time arrives if the weather be favourable remove the sash entirely from the frame to harden them off, so that they may suffer as little as possible when transferred to the open ground.

TUBEROUS BEGONIAS AT MOTE PARK GARDENS, MAIDSTONE.

THAT the popularity of the Tuberous Begonia is rapidly spreading we have ample evidence on all sides. It is now rarely we enter the exhibition tent, whether local or otherwise, but we see admirably flowered specimens, while in almost every private establishment valuable collections have been formed both for the flower garden and the conservatory. As regards the latter, I do not remember ever seeing a more beautiful sight than that of a house full of them in the above gardens, and which I had very recently the pleasure of inspecting. Something like 500 grandly flowered plants were neatly arranged, the majority occupying stages erected one above the other, while the rest were placed on a long narrow one in the front of the house. I noticed the plants were somewhat rather closely arranged, so that on entering the house the eye immediately rested on a solid mass of bloom. Several of the individual flowers were marvellous for size, some of which measured close on 7 inches in circumference, while the colour varied considerably, the most conspicuous being pure white, deep canary yellow, and apricot colour. I also observed that the pots are not extra large, which, considering the admirable condition of the plants shows they are at the hands of an adept. Mr. Davies informed me the strain was principally that of Messrs. J. Veitch & Sons.—H. M.

THE STONE PINE.

THE Stone Pine may perhaps be a native of China, where it is plentiful, as in the south of Europe it is seldom seen in situations far removed from human habitations. It occurs in the south of France, in Spain, in Greece, and in Barbary; but it is most closely associated in our minds with Italy. The brilliant skies of the landscapes of Claude have their effect frequently heightened by the contrast with its heavy masses of dark foliage. Gilpin is most enthusiastic in its praise:—

"After the Cedar," he says, "the Stone Pine deserves our notice. It is not indigenous to our soil, but, like the Cedar, it is in some degree naturalised; though in England it is rarely more than a puny, half-formed resemblance of the Italian Pine. The soft clime of Italy alone gives birth to the true picturesque Pine. There it always suggests ideas of broken porticos, Ionic pillars, triumphal arches, fragments of old temples, and a variety of classic ruins, which in Italian landscape it commonly adorns. The Stone Pine promises little in its infancy in point of picturesque beauty; it does not, like most of the Fir species, give an early indication of its future form. In its youth it is dwarfish and round-headed, with a short stem, and has rather the shape of a full-grown bush than of an increasing tree. As it grows older it does not soon deposit its formal shape. It is long a bush, though somewhat more irregular, and with a longer stem; but as it attains maturity its picturesque form increases fast. Its lengthening stem assumes commonly an easy sweep. It seldom, indeed, deviates much from a straight line; but that gentle deviation is very graceful, and, above all other lines, difficult to imitate. If, accidentally, either the stem or any of the larger branches take a larger sweep than usual, that sweep seldom fails to be graceful. It is also among the beauties of the Stone Pine that, as the

lateral branches decay, they generally leave stumps which, standing out in various parts of the stem, break the continuity of its lines. The bark is smoother than that of any other tree of the Pine kind, except the Weymouth; though we do not esteem this among its picturesque beauties. Its hue, however, which is warm and reddish, has a good effect; and it obtains a kind of roughness by peeling off in patches. The foliage of the Stone Pine is as beautiful as the stem. Its colour is a deep warm green; and its form, instead of breaking into acute angles, like many of the Pine race, is moulded into a flowing line by an assemblage of small masses. As age comes on its round clumpish head becomes more flat, spreading itself like a canopy, which is a form equally becoming; and thus we see what beauty may result from a tree with a round head, and without lateral branches, which requires, indeed, a good example to prove. When we look on an Ash or an Elm from which the lateral branches have been stripped, as is the practice in some countries, we are apt to think that no tree with a head placed on a long stem can be beautiful; yet in Nature's hands, which can mould so many forms of beauty, it may easily be effected."

It is doubtful whether the Stone Pine was grown in England before the time of Evelyn, or even before 1750, about which date Peter Collinson planted it, together with all the Conifers he could collect, at his house at Mill Hill, where many of the trees still remain. After the establishment of the beautiful pinetum at Dropmore, at the beginning of the present century, the taste for the regular but graceful outlines of the Conifers became general; but the Stone Pine is rarely seen with a height of 30 feet in this country.

In the south of Europe its wood is used for masts and general carpentry; but it is chiefly valued for its large edible seeds, which are used as food wherever the tree grows. They are three-quarters of an inch long without their wings, and about half as broad, and, being entirely free from resin, have a sweet taste, resembling that of the Hazel Nut. In Pliny's time they were preserved in honey, and now they are commonly used at dessert, or in sugarplums, instead of Almonds. If not kept in the cone, however, the abundant oil they contain becomes speedily rancid. Besides being much eaten by squirrels, they form the chief food of the cross-bill, a bird which occasionally visits this country, and whose beak is specially modified for their extraction from the cone. —(*Cassell's Familiar Trees.*)

THE WEATHER AND GARDEN CROPS.

BERKSHIRE.

We are eight miles N.E. of Newbury, 450 feet above sea level. Our rainfall from June 20th to July 31st was 6.30 inches, as against 1.35 inch during the same period last year. Rain fell on twenty-six days in July, with a total of 4.61 inches for the month. The aspect of vegetation shows a great contrast to last season. Bush fruits and Strawberries were plentiful and good, the Gooseberry caterpillar was troublesome, and in fact I consider this year more notable for the caterpillar plague than anything else, and the greatest hindrance from a gardening point of view. Our Apples, Pears, Plums, and Cherries on standards and pyramids are a complete failure owing to the ravages of the caterpillars at blooming time. Morello Cherries on walls, good crops and fine. To my mind any dressing that can be easily applied that would ward off the attacks of the grubs in the case of choice Apples and Pears is something to be sought for, as it is no use advocating planting as a profitable commercial undertaking till a remedy is found in the direction I have indicated. Vegetables have been plentiful and good, rather slow coming in, but of good quality. The Potato disease is somewhat prevalent in this district; the first earlies, such as Ashleaf, First and Best, &c., escaped, but second earlies of the American Rose type fared badly, particularly in close well cultivated cottage gardens, and which to the cottagers will be a great loss, as with many of them the Rose varieties are favourites. With regard to outdoor flowers, hardy herbaceous plants have been the most effective, such as scarlet Geums, Delphiniums, Stenactis, Poppies, Coreopses, &c., all of which have been most useful for cutting and decorative purposes. —R. MAHER, *Yattendon Court.*

BUCKINGHAMSHIRE.

We have had more rain in June and July than in any other months of the present year—viz., June, 2.8 inches; July, 3.72 inches. This, combined with an extreme low day and night temperature, has been very suitable for recently planted trees and shrubs; as a rule very few have died, and most have made good growth. Here flowering and ornamental shrubs have done well although they have flowered late; this has not affected the plants in any way, as those that produce ornamental berries are now fruiting freely, and are objects of beauty and interest to all lovers of this class of shrubs. As instances, *Sambucus racemosa* in the shrubberies here are laden with scarlet berries. *Hippophae rhamnoides* with its silvery leaves and yellow berries is very telling in masses; *Pyrus Aucuparia*, or Mountain Ash, is also fruiting freely, and is always a feature among shrubs and trees at this season of the year. *Spiraea arifolia*, *callosa*, *bella*, and *alba* have all been fine here. *Rubus coronaria* fl.-pl., *alba* pl., and *rubra* fl.-pl. are flowering freely on walls and fences. *Rubus leucodermis*, the yellow-fruited variety, should always have a place among this class of plants. *Olearia Haasti* is covered with white blossoms. China Roses have stood the cold and damp better than other varieties; planted in masses among shrubs they have a very pretty effect during the summer, being continuous bloomers. *Hydrangea paniculata* and *Hypericum calycinum* have

flowered and grown well. Among climbing plants *Clematis Jackmanni* has flowered extra well and made more growth than usual, proving that this class of plants prefer plenty of moisture. *Polygonum sachalinense* is over 12 feet high, and is one mass of white flowers. *Hyacinthus candicans* is blooming well, and the rain seems to have been an advantage to this plant, as the flower spikes are stronger than last year, although the bulbs have not been disturbed for six years. Tuberous Begonias have stood the wet and cold summer well, and are our gayest summer bedders. *Begonia ascotensis* has done well bedded out in masses. Abutilons have grown well, but have not flowered freely. Scarlet Pelargoniums have grown all to foliage. —J. SMITH, *Mentmore Gardens.*

JUNE and July have been very dull, cold, and wet, the thermometer often down to 39° and 40°, the nights very cold. Kitchen garden crops are good, early Potatoes, Cauliflowers, and Cabbage never better, and early Peas filled well. The later Peas have not filled well, they have grown beyond their average height, and some sorts have gone up 10 feet and overtopped the sticks. Kidney and Runner Beans are good and fruiting well. Late Potatoes promised well, but the disease is very prevalent amongst all sorts, and I fear will be rather serious for the cottagers. Fruit here is a very small crop, Apples, Pears, and Plums not half crops. Gooseberries, Currants, and Raspberries have been heavy crops, but very poor in flavour. Strawberries almost a failure, and deficient in flavour. Cherries not a heavy crop, but many were lost through the continuous rain. Peaches and Apricots were few outside. In the houses we have heavy crops; those in the early house fine and well coloured. The late trees have heavy crops, but will not swell well, as the borders have been too wet and cold. Late Grapes are also heavy crops, but I fear will not colour well.

Flower borders here are now beginning to look bright, but Pelargoniums have not thrown up many trusses until the last week; now they will soon look bright with flowers. Calceolarias have bloomed well, and Carnations also. The shrubs here suffered very much last season from the drought. Rhododendrons lost many of their leaves; we had but few flowers on them this year. —W. MOWBRAY, *Fulmer Gardens, Slough.*

CAMBRIDGESHIRE.

THE summer has certainly been a remarkable one, but not, as many as well as myself at first supposed, on account of excessive rainfall. The records show that during the months of June and July we had only 0.27 inch of rain above the average, and that for the whole of the year to the end of July we had less than the average by 1.13 inch. The exceptional character of the summer has been due to the almost entire absence of sun, continuous low temperatures, and frequent rather than heavy falls of rain. Rain seemed almost constant for weeks, but towards the 21st of August, when half an inch was registered, some herbaceous plants were in distress for want of water. The consequence of this dull and rainy weather was most conspicuously evident in the unusual growth of grass and weeds, which were difficult to keep under. The hay crop here and in the neighbourhood has practically been a failure. Herbaceous plants and trees seem not to have recovered from the effects of last year's drought, for while annuals in many cases have grown with unusual vigour, permanent vegetation, on the contrary, speaking generally, has not grown so strongly as usual. The effects of last year's dryness are clearly seen in the amount of seed that some trees have borne, due no doubt to complete ripening of the wood. Some annuals that have lately been very fine are *Waitzia aurea*, a fine yellow Everlasting; *Linum grandiflorum*, *Lavatera trimestris*, and *Statice Suwarowi*, which, with its long spikes of pink flowers, has been particularly ornamental, and for a *Statice* remarkably graceful. *Godetias* have grown unusually tall. Some plants, as for instance *Mignonette*, have not grown so strongly as usual, evidently for want of sun. *Fuchsias* I have considered less effective than usual for want of the same influence. *Yuccas*, on the other hand, which might be expected to need sun, have flowered finely, probably from the effects of last year's insolation. Lastly, it may be of interest to mention that the average of Cambridge rainfall for the last twenty-three years is 21.47 inches. —R. IRWIN LYNCH, *Cambridge Botanic Gardens.*

DORSETSHIRE.

THE rainfall has been largely in excess of the average for June and July here, and the temperature very low. Pelargoniums, Calceolarias, and other bedding plants have made plenty of growth, but are deficient of flowers. The Apple crop is very thin and the fruit small. Pears are a little better. Morello Cherries are fine. Plums are under the average. Strawberries and all bush fruits have been abundant but lack flavour. Vegetables have never done better. Winter crops are looking promising. Potatoes are extra good in quantity and quality. Ashleaf varieties are showing a little disease, Beauty of Hebron, White Elephant, and Magnum Bonum are fine, also Veitch's new Potato Chiswick Favourite. —D. WILLIAMS, *Canford Gardens, Wimborne.*

EAST LoTHIAN.

THE weather during the whole of week to August 24th has been of the most depressing character. Heavy showers either during the night or day, and an uninterruptedly close muggy atmosphere. Vegetable Marrows decay on the ground, Peas are decaying or mildewed, Roses decay in the bud, and Pelargoniums with many other flowers are just as bad. Currants are damping. Moorpark Apricots almost to a fruit cracked and spotted, and late Strawberries quite useless.

Peaches and Nectarines ripening indoors have scarcely any flavour. As to Apples and Pears we can hardly hope for them now to be over a third of the weight they are in good seasons, and tender varieties of the former are badly spotted. Curiously enough Potatoes are of excellent quality, some Snowdrops we are using at present being beautifully floury and of fine flavour. There has been a somewhat curious lack of fungoid parasites this season. Roses are almost free from mildew. The orange fungus has also kept away. There is no Potato disease yet, and no Hollyhock disease. As to the lateness of the season, Lime trees are now flowering. French Beans have not been gathered from out of doors. Carnations are beginning to open their buds, and Peas are being gathered from four successive sowings, the fifth or earliest having been cleared off, not for want of Peas to gather, but because the ground was wanted.—R. P. BROTHERSTON, *Tynninghame*.

KENT.

PERHAPS the following observations of the weather during August, taken daily at nine o'clock, may be interesting to some of the readers of the Journal if you can find room to insert them. The total rainfall for the month was 3.20 inches, rain falling on eleven days, the greatest amount in one day (1.51 inch) on the 1st, 0.90 falling between 6.30 and 7.30 P.M. The temperature was highest (73°) on the 9th and 10th, the wind being S.W., and lowest (52°) on the 18th, the wind being N.E. On thirteen days the temperature was below 60°, and only on the 9th and 10th was it above 70°. The maximum shade temperature taken at three o'clock was above 70° on nine days only, the highest (80°) being on the 9th.—ROBERT FILKINS, *Tower Fields Gardens, Keston, Kent*.

LIMERICK.

WE keep no record of rainfall here, consequently I am unable to state the amount in inches. I am sure, however, that we have not had anything like the amount that has fallen on the other side of the Channel. The nights have been somewhat cold. On three nights in June the thermometer fell to 36°, one night to 40°, seven to 44°, eight to 46°, seven to 48°, the remaining nights ranging from 50° to 54°. The highest day temperature during the month was 88°, the lowest 62°. One night only in July the thermometer fell to 36°, the remainder of the month ranging from 42° to 50°. The highest day temperature registered was 86°, this was reached on several occasions, the remaining days ranging from 64° to 82°. Roses have been splendid and without a trace of mildew. With the exception of one border Pelargoniums have done well. Heliotropes and Calceolarias were stationary for some time, but are good now. Begonias are grand; Violas are very good; Asters, Stocks, Zinnias, Calliopsis, Marigolds, Petunias, Viscaria, Papaver umbrosum, Tagetes, Phlox Drummondii, Bartonias, and Godetias are very fine. Mignonette is bad, Verbenas moderate. Herbaceous plants of all kinds were never better than this year.

Cauliflowers have been good. Peas have cropped splendidly, particularly Laxton's Alpha, Harrison's Glory, and Telephone. French Beans came up badly, but have since done well; the first dish was gathered in the open garden on August 6th. Runners were five days later. Onions and Beet are good; Carrots well nigh a failure, owing to the maggot. Celery is good, though several plants in the earliest batch bolted. Winter greens of all kinds look sturdy and healthy, and not much eaten by caterpillars. Potatoes are badly diseased, both root and branch, and get worse daily. Strawberries, Gooseberries, Raspberries, and Currants were very abundant, and all saved dry. Only a few Pears are fruiting. The same may be said of Plums. Apples and Nuts are a heavy crop. Apricots are a failure. Cherries similar to Pears, some trees loaded, others very lightly cropped.—R. WELLER, *Glenstal Castle Gardens, Munroe, Co. Limerick*.

SHROPSHIRE.

THE total rainfall for the present year ending June 30th was 2.57 inches under the average for the corresponding period during the past six years; but the heavy rainfall in July has made up the deficiency, the total rainfall amounting to 5.28 inches. Rain fell on twenty-seven days, and for the amount which fell in one month we have only one which exceeds 4 inches during the past six years, that one being the memorable wet May of 1886, when we registered 7.16 inches. In a general way fruit crops in this district are below the average, Apples, Pears, Plums, and Apricots being under the average. Peaches on open walls are an average crop, but so late that I am afraid they will not ripen. Cherries have been a good crop, especially Morellos, which are very fine. Strawberries and Raspberries were good average crops, but deficient in flavour. Black and Red Currants, and Gooseberries were over average crops. Quinces a failure. Walnuts, Filberts, and Cob Nuts are plentiful.

Vegetables. Early Potatoes have turned up a good crop. Late varieties are looking well, but in digging up some early Potatoes to-day, the 27th, we have found the first traces of disease. Roots in general are satisfactory. Onions a good crop, but small in size, and many with thick necks. Dwarf Kidney Beans have done badly. Scarlet Runners look fairly well, but are late. Early Peas a good crop. Second early varieties not so good. Late crops look promising. Cauliflowers have done badly.

Bedding-out plants have not been very satisfactory, Pelargoniums especially being short of flowers. Perennials have done fairly well, although those that were in flower in July were damaged by the heavy rains. Roses suffered very much from the same cause.—JOHN PENSON, *Willey Park Gardens, Broseley*.

AMERICAN SEEDSMEN AND HUMOUR.

TWENTY years ago you could plant a seed according to directions, and it would produce a plant which seemed to resemble in a general way the picture on the outside of the package. Now, under the fluctuating influences of irresponsible isotherms, phlegmatic springs, rare June weather and overdone weather in August, I find it almost impossible to produce a plant or vegetable which in any way resembles its portrait. Is it my fault or the fault of the climate?

I first noticed the change in the summer of 1872, I think. I purchased a small package of early Scotch plaid curled Kale with a beautiful picture on the outside. It was as good a picture of Scotch Kale as I ever saw. I could imagine how gay and light-hearted it was the day it went up to the studio and had its picture taken for this purpose. A short editorial paragraph under the picture stated that I should plant in quick, rich soil, in rows 4 inches apart, to a depth of one inch, cover lightly, and then roll. I did so. No farmer of my years enjoys rolling any better than I do.

In a few weeks the Kale came up, but turned out to be a canard. I then waited two weeks more, and other forms of vegetation made their appearance. None of them were Kale. A small delegation of bugs which deal mostly with Kale came into the garden one day, looked at the picture on the discarded paper, then examined what had crawled out through the ground, and went away. I began to fear then that climatic influences had been at work on the seeds, but I had not fully given up all hope.

At first the plants seemed to waver and hesitate over whether they had better be wild Parsnips or Lima Beans. Then I concluded that they had decided to be foliage plants or Rhubarb. But they did not try to live up to their portraits. Pretty soon I discovered that they had no bugs which seemed to go with them, and then I knew they were weeds. Things that are good to eat always have bugs and worms, while tansy and castor oil go through life unmolested.

I ordered a new style of Gladiolus eight years ago of a man who had his portrait in the bow of his seed catalogue. If he succeeds no better in resembling his portrait than his Gladiolus did in resembling theirs, he must be a human Onion, whose presence may be easily detected at a great distance.

Last year I planted the seeds of a Water Melon which I bought of a New York seedsman, who writes war articles winters and sells garden seeds in the spring. The portrait of this Water Melon would tempt any man to climb a nine-rail fence in the dead of night and forget all else in order to drown his better nature and his nose in its cool bosom. People came for miles to look at the picture of this Melon, and went away with a pleasant taste in their mouths.

The plants were a little sluggish, though I planted them in hills far apart each way in a rich, warm loam, enriched by everything that could make a sincere Water Melon get up and hump itself. The Melons were to be very large indeed with a centre like a Rose. According to the picture these Melons generally grew so large and plenty that most everybody had to put sideboards on the garden fence to keep them from falling over into other farms and annoying people who had all the Melons they needed. I fought squash bugs, cut worms, Hessian flies, chinch bugs, curculio, mange, pip, drough, dropsy, caterpillars, and contumely till the latter part of August, when a friend from India came to visit me. I decided to cut a Water Melon in honour of his arrival. When the proper moment had arrived and the dinner had progressed to the point of fruit, the tropical depths of my garden gave up their season's wealth in the shape of a low-browed Citron about as large and succulent as a hot ball.

I have had other similar experiences, and I think we ought to do something about it if we can. I have planted the seed of the Morning Glory and the Moon Flower and dreamed at night that my home looked like a florist's advertisement, but when leafy June came a bunch of Norway Oats and a hill of corn were trying to climb the strings nailed up for the use of my non-resident Vines. I have planted with song and laughter the seeds of the ostensible Pansy and Carnation, only in tears to reap the Bachelor's Button and the glistening foliage of the Sorghum plant. I have planted in faith and a deep, warm soil, with pleasing hope in my heart, and a dark-red picture on the outside of the package, only to harvest the low, vulgar Jimson Weed and the night-blooming Bull Thistle.

Does the mean temperature or the average rainfall have anything to do with it? If statistics are working these changes they ought to be stopped.—(*American Paper*.)

HORTICULTURAL SHOWS.

BRADING, ISLE OF WIGHT.

THE amateurs and cottagers, many of whom are allotment holders, were given an opportunity on Tuesday last, August 28th, of bringing out their productions and competing for prizes offered by the above Society. Horticultural industry seems to have taken a firm hold in the neighbourhood, and a few of the leading spirits determined that Brading should not be behind in encouraging the interest. Lady Oglander, the Lady of the Manor, from the ancient barony of Nunwell, kindly gave her support and offered her beautifully timbered park to hold the Show in. Like many others this year the opening day was marred by a perfect downpour of rain, but the second day proved fine, and enabled many visitors to visit the park and Exhibition. The affair was a decided

success, and Dr. Lucas, the Treasurer, Mr. Sims, the Hon. Sec., and the Committee generally were well encouraged by the results of the first Show.

Mr. Wilkens, gardener to W. S. Ridley, Esq.; Mr. A. Tolley, St. Helens; and Mr. R. Tolley, gardener to Lady Oglander, filled the centre stage of the marquee with stove and greenhouse flowering plants, which were a grand attraction. The stage around was filled with the various classes of stands and baskets of flowers, bouquets, fruits, and vegetables. The productions were very creditable; the baskets of flowers showed great taste in the arrangement, but some of the Potatoes were coarse. Prizes were awarded for the best kept and cropped allotment ground. G. R. Lucas, Esq., Mrs. Morris, Mr. J. W. Pain, Mr. Barham, Mr. G. Corbett, Mr. A. Bownin, and Mrs. Lucas were the principal contributors to the amateurs' division. The basket of cut flowers from the last named lady was much admired. Mr. Frank Cooper was first for a dish of black Grapes, showing some good Black Hamburgs, Mr. A. Tolley second, but for white Grapes the latter was first with good Muscat of Alexandria. The dish of Figs that gained the first prize, exhibited by Mrs. Hills of Adgestone, being as fine as we have ever seen. The heaviest Potatoes were a dish of The Daniels, second was White Elephants. Fidler's Prolific was first in the class for kidneys, and Radstock Beauty in the class for round Potatoes. The Rev. E. Summers and friends from the vicarage contributed some beautiful stands of cut flowers, and a model garden; Miss Hinxman a very attractive epergne of cut flowers, and Mrs. Senior some beautifully arranged baskets of flowers. Mr. Frank Cooper also exhibited a stand of six bunches of well finished Black Hamburg Grapes.

An object of especial interest was a fine collection of vegetables exhibited, not for competition, by Mr. C. Orchard, bailiff to the Brading Harbour Company. There were twenty-five varieties arranged in the group, all of which were grown on the reclaimed land. The collection was considered one of the finest that had ever been exhibited in the island. Sutton's Masterpiece, Sutton's Abundance, and Sutton's Satisfaction Potatoes were particularly clean and good. Cannell's Come to Stay New Potato was much admired. Sutton's Early Gem and New Intermediate Carrot, Early London Cauliflower, Sutton's Satisfaction, Pride of the Market, and President Garfield Peas were also good; Beet-roots, Parsnips, and Onions being also in like proportions that quite astonished the natives that knew the sand and mud banks that were under the sea but a few years ago. Segt. Williams, Brading, also exhibited six dishes of vegetables, not for competition.

SHERBORNE.—AUGUST 29TH.

THIS Society has been established twenty-seven years, and on the whole the annual exhibitions have been highly successful. Latterly, however, the fixtures have been rather unfortunate, and it was earnestly hoped that more favourable weather than usual would have been experienced; an extra large attendance of visitors being needed in order to bring up the funds somewhat. Unfortunately frequent very heavy showers much marred the proceedings, and in all probability another deficit resulted. The Show was held among the ruins of the old Sherborne Castle, a spot highly suitable both on account of its picturesqueness, and also for the shelter much needed for the various tents. An excellent display of plants, flowers, fruit, and vegetables was arranged, which reflected much credit on all concerned. Mr. G. F. Stokes has long and efficiently filled the post of Honorary Secretary, and a numerous Committee render him good assistance in various ways.

The principal prizes were offered for a collection of twelve ornamental plants in or out of flower, and with these Mr. T. Wilkins, gardener to T. M. Guest, Esq., Inwood House, was first, having capital specimens, and the second prize was awarded to Mr. J. Curry, gardener to Col. Pepper, Salisbury. For the best miscellaneous collection of stove and greenhouse plants Mr. Wilkins was again well first. Mr. G. Runnacles, gardener to C. Thurburn, Esq., Leweston House, was second with a group of smaller but very serviceable plants, Mr. T. Curry being a very close third. There were six entries with groups of plants arranged for effect in a half circle measuring 12 feet the longest way. These groups were all good and quite a feature in the Exhibition. Mr. G. Runnacles was awarded the premier prize, and certainly deserved it, his arrangement being very light and effective, all the plants used being of good quality, and no crowding was observable. The groundwork was formed principally of Maidenhair Fern, out of this springing a variety of highly coloured Crotons, Dracænas, Pandanus, several elegant Palms, the flowering plants including Impatiens Hawkeri, and which was very attractive, Gloxinias, Begonias, and Gloriosa superba. Mr. W. G. Pragnell, gardener to J. D. W. Digby, Esq., Sherborne Castle, took the second prize with a neatly arranged group; Mr. J. Witherington, gardener to Major McAdam, being third, his group being very pleasing though slightly overdone with Liliun auratum; while the fourth prize fell to Mr. Wilkins, who also had a very creditable group somewhat disfigured by too much of the Panicum variegatum in front.

Ferns are always exceptionally good at Sherborne. With twelve varieties Mr. J. Crump, gardener to W. Neal, Esq., Kingsdon, was first, Mr. T. Wilkins was a good second. In the open class for Begonias Mr. G. H. Copp, gardener to W. E. S. Erle Drax, Esq., Holnest Park, was deservedly awarded the first prize, and he was also first for dwarf Cockscorns, the second prize in this instance going to Mr. G. R. Davey, gardener to R. Stainer, Esq., Mapperton House. The best six Fuchsias were staged by Mr. G. Gillingham, gardener to R. Phelps, Esq., Yeovil; the second prize going to Mr. C. Anthony, gardener to T. Moore, Esq.,

Yeovil, both having medium-sized, well-flowered plants. Mr. C. Anthony was first for Balsams, Mr. Copp being a good second, and Mr. Crossman, gardener to J. Brutton, Esq., Yeovil, third. The best Zonal Pelargoniums were staged by Mr. J. Andrews, gardener to General Place, Thornford, Mr. C. Anthony taking the second prize.

Cut flowers were numerous, and in some instances the quality was good. Roses had been sadly battered by wind and rain the day previous, but in spite of this Mr. Campbell, gardener to Dr. Budd, Bath, succeeded in staging a very creditable stand of twelve triplets, and was first, the second prize going to Messrs. Keynes, Williams & Co., Salisbury. Mr. Campbell was also first for twelve single blooms, Mr. J. Burgess, Bristol, second. In the open class for twenty-four Dahlias Messrs. Keynes, Williams & Co. were easily first; Mr. J. Nation, Taunton, was second in this instance, and first in the class confined to amateurs, having several good blooms in each stand. Asters were remarkably well shown, the principal prizewinners being Mr. W. J. Jones, Bath; Mr. G. J. Garraway, Bath; and Mr. Copp. Mr. S. Tottle, Taunton, was first for Gladioli, and Mr. R. H. Poynter, Taunton, second. The best stand of twelve varieties of cut flowers was sent by Mr. Montagu Williams, the second prize going to Mr. R. H. Poynter. For a tastefully arranged basket of cut flowers Mr. C. H. Perkins, gardener to Col. Hambro, M.P. Melton Abbey, was first, and Mr. S. Kidley, gardener to H. A. Hellyar, Esq., Coker Court, second. Mr. W. F. England, Chard, was awarded a first prize for an ornamental device, and with a vase of wild flowers Mrs. H. Baker, Sherborne, was first; Mr. W. Morris, Sherborne, second; and Miss Paynter, Sherborne, third. Mrs. Allan C. Dyer, Taunton, was first for a fine hand bouquet, Miss M. Poynter, Taunton, being second, and Mrs. Perkins, Milton Abbey, third.

One large tent was principally devoted to fruit and vegetables, and, as usual, a capital display of each was staged. There were five entries in the class for eight dishes of fruit, Pine Apple excluded, the first prize for which was a silver cup valued at five guineas. This was won by Mr. J. Lloyd, gardener to Vincent Stuckey, Esq., Hill House, Langport, who had fine bunches of Black Hamburg and fairly good Muscat of Alexandria Grapes, a good Longleat Perfection Melon, Crimson Galande Peaches, Humboldt Nectarines, Florence Cherries, Moorpark Apricots, and Goliath Plums, all of good size and colour, this being altogether a highly creditable collection. Mr. W. G. Pragnell was at first awarded the second prize, but owing to having too many fruit in one dish had to be disqualified, and was awarded an extra prize. Mr. A. Crossman took the second prize for a good all-round collection only a few points below the preceding, and Mr. C. H. Perkins was third. Mr. Pragnell was first and Mr. J. Lloyd second with a Pine Apple. The last named was placed first in the class for any variety of Melon, a capital fruit of Longleat Perfection, Mr. T. Wilkins being second with Hero of Lookinge beautifully ripened. There was less competition than usual in the Grape classes. Mr. W. J. Chalk, gardener to G. Read, Esq., Wilton, was first for three very fine well finished bunches of Black Hamburg, Mr. G. R. Daley, gardener to R. Stainer, Esq., being a creditable second. Mr. Crossman was first for Muscat of Alexandria and Mr. Lloyd second, the first named having much the finest bunches. In the class for any other white variety Mr. W. Dennis, gardener to Lady Westminster, was first with fairly well finished Buckland Sweetwater, and Mr. Pragnell second with Foster's Seedling. In a corresponding class for black Grapes Mr. Wilkins received a second prize for Alnwick Seedling. A few good dishes of Peaches were shown, Mr. J. Lloyd being first with a good dish of Noblesse, the second prize going to Mr. G. R. Daley, who had Royal George in good condition. In the class for outdoor Peaches Mr. Pragnell was first for a well ripened dish of Hale's Early, Mr. W. C. Bowers, gardener to C. Holford, Esq., Castle Hill, being second with Dessc Hâtive, not quite ripe. In the class for indoor Nectarines Mr. G. R. Daley staged a remarkably fine dish of Pitt-maston Orange, and was first, the second prize going to Mr. C. H. Perkins for good Elruge. Mr. J. Gritton, gardener to Mrs. Moody, Stapleton House, was first for outdoor Nectarines, and Mr. C. H. Perkins second. The last named was first and Mr. Lloyd second with Pears, both having well ripened Jargonelle. The prizewinners with Plums were Messrs. J. Crump, W. Dennis, M. Paulley (gardener to A. W. B. Clarke, Esq.), S. Kidley, and J. Andrews, the varieties shown in good condition being Jefferson's, Kirke's, Greengage, and Washington. Morello Cherries were very fine. Mr. S. Kidley was first and Mr. J. Crump second, an extra prize being awarded to Mr. Lloyd for a good dish of Florence. Mr. Pragnell was most successful with Apples, and Mr. T. Evry, Bath, also took a first prize in these classes.

The Sherborne district has long been famous for the excellency of the vegetables produced in it, and shown in various parts of the country, Mr. W. J. Pragnell for many years being remarkably successful with them. This veteran is still capable of holding his own, but is pressed very closely by Messrs. Wilkins, Copp, and other gardeners in the neighbourhood, their various contributions forming a display not surpassed anywhere as far as quality and setting up is concerned. With twelve varieties Mr. Pragnell was placed first, his collection consisting of very fine Rousham Park Onions, Globe Artichokes, Autumn Giant Cauliflowers, Veitch's Matchless Carrots, Prodigy Peas, Wright's Grove White Celery, Snowball Turnips, Tender and True Cucumber, Giant White Runner Beans, Ellacombe's Improved Parsnips, Sutton's Satisfaction Potato, and Hackwood Park Tomato. Mr. G. H. Copp was a good second, and Mr. T. Wilkins a close third. With eight varieties Mr. M. Paulley took the lead, this collection consisting of Autumn Giant Cauliflower, Grove White Celery, Rousham Park Onion, Tender and True Cucumber, Matchless Carrots, No Plus Ultra Pea, Hathaway's

Excelsior Tomato, and International Kidney Potato, all in excellent condition. Mr. C. Bowers followed closely, and Mr. A. Philpott, gardener to W. Parson, Esq., Sherborne, was third. Mr. Copp was first for Celery, having very fine Grove White, and Mr. M. Paulley second. Mr. Pragnell was first and Mr. Wilkins second for spring-sown Onions, both have very fine bulbs of the White Spanish type. Mr. Lloyd was first for Tripolis, and Mr. Crossman second. Mr. Copp was first in the class for round Potatoes, staging a fine dish of Sutton's Satisfaction; Mr. Pragnell was second with Reading Russet. With kidneys, Mr. C. Bowers was first, and Mr. Gillingham second. Mr. Runnacles was well first for a brace of Cucumbers, staging Tender and True in good condition; Mr. G. Garraway, Bath, was second. Messrs. C. Bowers, Garraway, J. Harris, gardener to M. Williams, Esq., and J. Nation were also successful in the single dish classes. Several non-competitive displays of plants and cut flowers were made, which materially added to the attractiveness of the Exhibition. Messrs. R. Veitch & Co., Exeter, had a good bank of plants and stands of Carnations, Roses, Begonias, Gladioli, Asters, herbaceous plants, and Dahlias. Among the latter, King of the Cactus, Mrs. Hawkins, *Picta formosissima*, Zulu, *Germania nova*, and W. Pearce were the most attractive. Mr. Scott, Yeovil, also had a good variety of Roses, Dahlias, Begonias, and other cut flowers. A fine lot of Dahlias, including Pompon, single, fancy, and show varieties, were staged by Messrs. Keynes, Williams & Co., Salisbury. A stand of Amphion, Panthea, Pelican, Asia, Empress of India, Juarez, Mrs. Tait, and Mrs. Hawkins, all classed as Cactus Dahlias, was most attractive. Messrs. Kelway & Son, Langport, arranged several fine stands of Gladioli, and also had a capital display of Gaillardias and other hardy flowers. From Mr. B. R. Davis, Yeovil, came several stands of Dahlias in variety, and a remarkably fine display of Tuberous Begonia blooms. These were arranged in bouquets, vases, and stands, and came in for a good share of attention. Among the varieties shown and principally raised by Mr. Davis, the best were Eucharis, a good single white; Gardenia, a fine double white; Picotee, Miss Hayward, T. Baines, Davis' Camellia-flowered; Ella L. Davis, National, Mauvette, Lord R. Churchill, Severn King, and J. E. Davis, all first-class doubles.

HARPENDEN.

THE Harpenden Horticultural Society held the tenth annual Show on the 29th ult., in most unfavourable weather, and, to add to the difficulties, the hurricane that passed over the district on the previous night completely demolished one of the tents, and it was only by the active exertions of several of the Committee, who spent the greater part of the night on the show ground, that the large tent in which the open classes and gardeners' exhibits are staged was saved. However, in spite of the difficulties and disasters, from a purely horticultural point of view it was a great success, the entries being the largest the Society has ever received, in many cases the exhibits being better than those of former years. In the open classes we missed the grand flowering plants so successfully exhibited by Mr. Underwood, the gardener at High Firs, Harpenden. Owing to the death of this exhibitor's employer the Society has lost a firm supporter. In the plant classes Mr. Nutting, gardener to J. B. Maple, Esq., M.P., Childwickbury, St. Albans, was the most successful exhibitor, taking first in the class for six stove and greenhouse plants in bloom. Mr. Task, gardener to P. Bosanquet, Esq., Pondfield, Little Berhampstead, second. In the class for six foliage, Mr. Nutting first, Mr. Task second, and Mr. Emptage, gardener to T. S. Hill, Esq., Hawkswick, St. Albans, third. For six Ferns, Mr. Emptage was first, Mr. Nutting second, Mr. Pepper, Tewin Water, Welwyn, third. For a group arranged for effect Mr. Nutting was a good first with an exceedingly pretty arrangement; Mr. Emptage second with a more massive style, and Mr. Task third. Twelve table plants, Mr. Nutting first; Mr. Brown, Moat Mount, Mill Hill, second. Zonal Pelargoniums were well shown, the prizetakers being Mr. Sibley, Harpenden, Mr. Littlechild, Highfields, St. Albans, and R. Mather, Esq., Harpenden. Mr. Sibley and Mr. Smith, Harpenden, were successful with Begonias. Fuchsias and Coleuses were well shown. Herbaceous cut flowers were a feature of the Show, Mr. Henshaw staging a grand lot. The same exhibitor was also to the fore with Pompon Dahlias. Roses were grand, the honours going to Messrs. Paul and Son, Cheshunt, Rev. W. H. Jackson, Stagsden, and the Rev. F. H. Gall, Hitchin. Stove and greenhouse cut flowers were good, Mr. Brown staging an ideal collection.

In the fruit classes Mr. Brown was first for eight dishes, Mr. Nutting second, and Mr. Tilbury, Lamer Park, third. For black Grapes Mr. Brown was a good first, staging grand Black Hamburgs. In the class for white Grapes Mr. Nutting was first, showing bunches of Muscat of Alexandria. Mr. Nutting was also first for Peaches with a grand dish of Princess of Wales, the six fruits weighing 3 lbs. 2 ozs. In the vegetable classes Mr. Pepper was very successful, being first for a collection of nine varieties, and first for six varieties; Mr. Faint, Marden Hall, Hertford, being a close second. Mr. Pepper was also first for Carter's collection of vegetables. As is usual at Harpenden the amateurs and cottagers came out very strong, and made an exceedingly fine exhibit of vegetables, cut flowers, and plants.

The prizes for table decorations were not keenly contested, there being but two entries. Mrs. Sell, Luton, was first with a very pretty light arrangement; Miss Maple, a young lady of twelve years of age, followed very closely, the chief fault in her table being that it was rather too heavy. Bouquets, stands, wreaths, and buttonholes were well shown. Amongst the non-competing exhibits Messrs. W. Paul & Son certainly carried off the palm with a choice assortment of Roses, Dahlias, herbaceous flowers and foliage. In this exhibit was a very tasteful

arrangement of Lapagerias which reflected great credit upon the designer. Messrs. Paul & Son, Cheshunt, also staged some fine Roses. Mr. Ware put up a magnificent assortment of herbaceous flowers; Messrs. Cutbush a choice collection of Roses; and Mr. Merrit, gardener to Lord Dacre, Kimpton Hoo, Welwyn, staged some fine Potatoes and six splendid bunches of Madresfield Court Grapes; Mr. Nutting had some handsome Palms 12 feet high, which greatly added to the general effect in the large tent; Mrs. Josling, St. Albans, sent some fine agricultural roots, and a group came from Sir J. B. Lawes, Rothamsted.

SANDY AND DISTRICT.

THE twentieth annual Exhibition of this Society was held on Friday last in the grounds of Sandy Place, and probably no society established on similar lines and so conservatively conducted up to the very verge of its majority without courting extraneous attractions, has achieved such continued and increasing success and popularity, this favourite annual gathering having become not only the chief horticultural trysting ground for a large portion of the four counties of Beds, Hunts, Cambs, and Herts, but vicing in popularity as a general holiday for the district with the fête of St. Lubbock. The Show on Friday, which in addition to horticultural produce combined poultry, farm produce, bees, &c., was an all-round success, the one weak point perhaps being the limited and sparse display of fruit, which generally showed deficiency in quality and colour, owing to the unfavourable season.

In the open class for ten stove and greenhouse plants in flower there was good competition, Mr. Jas. Cypher of the Exotic Nurseries, Cheltenham, taking the lead with large and well flowered specimens, including grand plants of *Bougainvillea glabra* and *Phenocoma prolifera* Barnesi, fine *Erica Irbyana*, Thompsoni, and *Marnockiana*; *Clerodendron Balfourianum*, *Statice profusa*, *Allamanda nobilis*, and *Ixoras Pilgrimi* and *Fraseri*. Mr. W. Finch, gardener to J. Marriott, Esq., Coventry, was placed second with fully flowered and regular plants, all in fine condition, but somewhat smaller, his specimens of *Dipladenia amabilis*, *Erica Aitoniana turgida*, *Allamanda nobilis*, and *Lapageria rosea* commanding good attention. The third prize was secured by Mr. W. Rabbitt, gardener to General Pearson, C.B., The Hasells, Sandy, who staged some highly creditable and but slightly inferior plants; and Mr. G. Redman, gardener to J. H. Goodgames, Esq., Eynesbury, Hunts, was allotted deservedly the fourth place with smaller but healthy and well flowered specimens. For twelve Zonal Pelargoniums in the open class Mr. Redman was first, having well flowered plants of Hettie, President Thiers, Niphotos, Dr. Orton, Mrs. Wright, Le Cygne, and Henry Jacoby; Mr. Rabbitt following as second with bright coloured sorts, including Madame Titians, Dr. Orton, Royalty, and Queen of the Belgians, all very good. Some good Ferns and plants were also shown in the amateurs' division, Mr. G. Claydon, gardener to J. H. Astell, Esq., Woodbury Hall, Hunts, taking first place for Ferns. Fuchsias from Mr. Rabbitt and Coleus from the same exhibitor were especially noticeable.

Cut flowers were very largely shown. For forty-eight Roses in the open class, not less than twenty-four varieties, Messrs. J. & W. H. Burch of Peterborough had the best stand, their flowers being very bright and clean, that good old Rose Duchesse de Morny, with Star of Waltham, The Bride, Comtesse de Serenye, Alphonse Souper, Horace Vernet, Lady Sheffield, and Emile Hausberg being amongst their best. Messrs. Paul and Son, Old Nurseries, Cheshunt, were a good second, showing Victor Hugo, Mrs. John Laing, Madame I. Pereire, Mrs. Geo. Dickson, and Countess of Oxford in good form; Messrs. Burrell & Co., Howe House Nurseries, Cambridge, being third, Horace Vernet and Catherine Mermet being noticeable.

For twenty-four Roses open to amateurs, not less than twenty-four varieties, Mr. C. Lindsell, Hitchin, was first with a creditable stand of autumn blossoms, which included two fine flowers of Mrs. John Laing, a promising autumn Rose; Merveille de Lyon, A. K. Williams, Catherine Mermet, Marie Verdier, Horace Vernet, and Duke of Connaught being also good, Mr. P. Meyer, Orwell taking second place. In the open class for twenty-four spikes of Gladiolus, Messrs. Burrell & Co. had a very fine stand, chiefly their own seedlings, in the raising of which they bid fair to eclipse some of the great continental growers. Nobilis, a large well-formed flower, carmine rose coloured with white lines, and a splendid spike, will probably take first rank amongst English raised varieties. Dorothy, another fine seedling, colour salmon rose with white throat and blotches, was also striking. Vivid, Memnon, Shakespeare, Irene, and Matador were also good amongst the older varieties. Messrs. Burrell were awarded first honours for this stand.

Dahlias for the season were fairly well shown, the veteran Mr. H. Glascock, of Bishop's Stortford, although strongly armed, had to succumb to a slightly superior stand from Messrs. Heath & Son, Cheltenham, who were placed first for twenty-four blooms, Mr. Gladstone, Mrs. Dodd, and Eclipse being amongst their best blooms, Mrs. Theobald and Mrs. G. Rawlings being noticeable also in Mr. Glascock's box. Mr. Glascock was placed first for six fanatics in the amateurs' class with some good blooms, and Mr. P. Meyer second. For twelve Dahlias in the same class, Mr. Joseph Arnold, of Leighton Buzzard, showed some very fine blooms, and secured first place. Asters, with the exception of a remarkably fine stand of "The Comet" (Haage and Schmidt, 1887), a very striking and distinctly white-striped rose flower like a large reflexed Chrysanthemum, and to which a first-class certificate was awarded, were not remarkable. The best twelve Truffaut's coming from Mr. W. Bourne, Cambridge, the same exhibitor also leading with fine African Marigolds and a good stand of hardy cut flowers.

A well set up display of flowers, chiefly consisting of bouquet and

single Dahlias, was also set up by Mr. T. S. Ware of Hale Farm Nurseries, Tottenham, not for competition. There was good competition in the class for table decorations, Miss C. S. Orlebar of Willington Rectory, Beds, taking the first prize for a very effective but somewhat conspicuous display, consisting mainly of the scarlet *Tacsonia*, white flowers and Ferns; Miss E. C. Pearson of The Hasells, Sandy, for second prize, having a tasteful display, in which *Clematis vitalba* and Ferns, lightened up with *Dahlia Juarezi*, were the chief features. Third, Miss M. A. Mould, Ickwell House, Biggleswade, who had also a light and pretty table. Natural dried flowers in nicely arranged cases were also exhibited by Mr. H. F. Southam of Lyndhurst, New Brighton, not for competition.

FRUIT.—In this department Mr. G. Allis, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, well sustained his position as a successful competitor at this Exhibition, securing first honours for eight varieties, showing fine Buckland Sweetwater and Lady Downe's Grapes, Melon, Peaches, Nectarines, Plums, Cherries, and Cox's Orange Pippin Apples of 1887 growth in fine condition; Mr. R. Carter, gardener to Col. Duncombe, Waresley Park, Hunts, taking second place. For six varieties Mr. Redman was first, and Mr. C. Forbes, Trumpington, Cambs, second. For two bunches of Black Hamburgh Grapes Mr. F. Faint, Hertford, was first, and Mr. Forbes second. For two bunches of black Grapes, Black Hamburghs excluded, Mr. Forbes was first and Mr. Allis second. For two bunches of Muscats Mr. Carter was first and Mr. Forbes second; and for two bunches of white Grapes, Muscats excluded, Mr. Allis was first with very fine Buckland Sweetwater, and Mr. Carter second with Mrs. Pearson. For scarlet-fleshed Melon Mr. Allis was first, and for green-fleshed Mr. Claydon; Mr. Dale, gardener to M. Foster, Esq., Sandy Place, taking first for a fine dish of Negro Largo Figs.

Vegetables were shown in enormous quantity, and for the collection of twelve varieties there was a very strong and close competition, Mr. G. Robinson, gardener to F. Howard, Esq., Abbey Close, Bedford, securing first place, Mr. Faint coming second, and Mr. A. Burgess, The Gardens, Wimpole, Cambs, third. For six varieties in the amateurs' class Mr. S. Rorby, Rennold, Beds, was to the fore, Mr. Allis second, and the Rev. W. E. Jackson, Stotfold, third. For twelve white kidney Potatoes Mr. R. Waller, gardener to Jas. Howard, Esq., Clapham Park, Beds, was first with a very fine dish of Vicar of Croxall, a promising looking variety. Mr. Waller was also first for twelve coloured kidney Potatoes. For twelve round whites Mr. Faint came first, Mr. Robinson leading in the class for twelve coloured rounds. Peas were fairly well shown for the season, the leading varieties being Duke of Albany, Evolution, and Ne Plus Ultra. For a collection of Potatoes Mr. F. Hazell, Cambridge, had a fine box; Mr. G. Robinson, and Mr. W. Raynes, Arrington, Cambs, competing very closely for second and third places. A collection of eighteen promising seedlings were also shown by Mr. A. Harris of Woburn, chiefly from seed sown in 1886 and 1887; coloured sorts, however, were predominant.

The silver medal offered by Messrs. W. Wood & Son for the best dish of fruit in the Show grown with their manure was awarded to Mr. W. Finch, Coventry, for three very fine specimens of a Melon named Finch's Seedling.

FRUIT FORCING.

VINES.—*Earliest Forced.*—Those that are to afford ripe Grapes in late April or early May should be pruned at once. It is not necessary to wait till all the leaves have fallen before pruning; only the wood must be brown and hard and the leaves turning yellow. The pruning will cause the Vines to rest more quickly and thoroughly. In pruning judgment is necessary, each Vine being pruned according to experience of its doings in the past. If it bear fruit freely when pruned to one or two buds, the bunches being as large as desired, and the Vine shows no tendency to weakness, then by all means keep to the system that is found to answer; but if the Vines, or any of them, from continuous early forcing, full cropping, or other cause show a tendency to weakness, the fruit being fewer and smaller, one or both, leaving the shoots a bud or two longer than usual will mostly result in a more certain show of fruit in large bunches, and when larger bunches than ordinary are wanted buds that are fully developed on the stoutest parts must be selected for pruning to. By pruning to two buds the serviceable bunch of a pound or a little more may be had on healthy Vines, but in some cases this close pruning does not result in fruit of that size, and in some instances none; therefore the pruning must be regulated according to the condition of the Vines and the size of bunch that is required. There is an evil in pruning less closely than usual, which is apt to be overlooked—viz., allowing the Vines to carry quite as many bunches of 2 lbs. weight as they by the closer pruning did of bunches weighing a pound.

Thoroughly cleanse the house and the Vines also. Any weakly Vines or those in an unsatisfactory state may be improved by removing the soil down to the roots and supplying fresh turfy loam with an admixture of a tenth of clay marl if the soil be light, or of old mortar

rubish if heavy, and a twentieth part of steamed crushed bones, lifting any roots available for the purpose, laying them out upon the fresh compost, and covering them not deeper than 3 or 4 inches. This is best done before the fall of the leaf. It is a mistake to allow Vines when at rest to become very dry at the roots; comparative dryness is desirable, yet great injury is caused by allowing the soil to become dust dry. The outside border should have a covering to protect the roots from the heavy autumn rains, which reduce the temperature considerably. Glass lights are every way preferable, throwing off heavy rains and allowing the sun's heat to penetrate the soil. Many, however, are obliged to be content with a covering of leaves, bracken, or litter after the weather sets in cold, and though convinced that good Grapes can be produced without material to throw off the wet, rains, and snow, yet reason and practice justify their employment wherever available for the exclusion of moisture in undue proportion to the requirements of the Vines.

Pot Vines.—It is highly prejudicial to allow these to become very dry at the roots when at rest, especially those for starting in November. They should have moisture to keep the roots fresh, those for that purpose—i.e., early fruiting, being now completely at rest, the wood thoroughly ripe, the laterals cut close home, and the canes shortened to about 6 feet, more or less according to the situation of the plump eyes. Whilst the cuts are dry dress them with styptic or "knotting" to prevent further trouble from bleeding. They should be kept in a cool airy house. Place later Vines in pots outdoors to ripen or harden. The south side of a wall or fence is suitable, the roots being protected from heavy rains, supplying sufficient water only to prevent the destruction of the root fibres.

Late Grapes.—The weather in most places has been extremely unfavourable for the ripening of late Grapes, the borders being saturated with moisture outside, resulting in an undue amount of lateral growth and the swelling of the berries to an unusual size. Keep the laterals well thinned, and thereby admit as much light as possible to insure the finishing of the crop, not by large reductions of foliage at one time, but by frequent pinchings. Where spare lights are at hand employ them to throw off heavy rains and to secure greater warmth to the soil. This will not only assist the present crop to ripen—to finish satisfactorily—but will help to secure the ripening of the wood. Fires will be necessary to maintain a night temperature of 70° to 75°, falling 5° or even 10° through the night, but getting up the temperature early in the morning to 70° or 75° with a little ventilation, at which keep through the day artificially with an advance to 80°, 85°, or even 90° from sun heat, affording Muscats and others that require a high temperature to finish off well a temperature of 80° to 85° by day under any circumstances, and 70° to 75° at night, accompanied with a free circulation of air day and night, as it will require sharp firing to finish off late Grapes before the days are too short to admit of its continuance; indeed, more may be done in the next few weeks than the remainder of the year. Those Grapes well advanced in ripening may have the atmospheric moisture gradually reduced; those only colouring should have a moderate amount of moisture to assist their swelling, not neglecting the inside borders, as may be necessary to insure an efficiency of moisture.

Young Vines, especially those that have made a strong growth, are late in ripening, and must be assisted with fire heat, maintaining a minimum of 65° and maximum of 75° from fire heat, continuing it until the wood is ripe, accompanied with free top and front ventilation. The laterals must be gradually cut back, being careful, however, not to do it so as to cause the principal buds to start into growth. Do not allow the laterals on any account to interfere with the principal leaves, which must have direct light and air in order to the perfecting of the buds at their base.

THE FLOWER GARDEN.

Zonal Pelargoniums.—Cuttings of these are very soft and sappy, and more than ordinary pains must be taken or they will fail to strike. They ought to be at once taken off the old plants, duly cut to a joint and trimmed, and then laid in a dry frame or house till such time as the wounds are thoroughly dried. If this old fashioned plan is not adopted, the least that can be done is to use rather dry soil for the pots and boxes, and give no water for a week or more. In any case only enough water should be given to prevent shrivelling, as if the soil about sappy late-struck cuttings is saturated with moisture at any time they are liable to "damp off." Whether they shall be struck and wintered in pots or boxes must depend upon circumstances. Where large numbers are required, these being stored in well ventilated houses or dry heated pits, shallow boxes with plenty of drainage are preferable, especially for the green-foliaged varieties. Where, however, the plants have to be wintered in rather damp pits, frames, or various makeshift positions, fewer will be lost if pots are used. These may be from 4-inch to 8-inch in size, and should be well drained and firmly filled with gritty soil, the cuttings being dibbled in rather thickly. Pots are decidedly to be preferred for all the delicate bronze, silver, and golden variegated varieties. None should be left in the open in showery weather, but all ought to be set either in frames or pits, and plenty of light and air admitted to them. The aim should be to encourage a strong root action accompanied with little or no top growth.

Tuberous Begonias.—When cuttings of these can be procured they may be struck very much in the same manner as Pelargoniums. It is too late to insert them in the open ground or at the foot of sunny walls and frames; pits or frames are the best positions for propagating them now. Placed in heat or closed frames they will nearly all damp off. Enough water should be given to prevent the soil becoming very dry or the cuttings flagging badly, but it ought to be gradually with-

held after a tiny tuber has been formed and the top has commenced to die down. Late-raised seedlings which are not large enough to plant out will form small bulbs before the tops die down, and if these are kept in a cool house, pit, or dry shed they will be available for bedding out next season. On the whole Begonias have done well this season, and are far more effective than Zonal Pelargoniums.

Verbenas.—A showery summer suits Verbenas much better than hot and dry weather, and plenty of clean healthy young cuttings are available in most instances. The best for striking are the young flowerless shoots that spring from the centre of the plant, and these root readily in gentle heat. They should be made into short cuttings, at once, dibbled thinly in well drained 5-inch pots filled with light loamy soil faced with sand, and then placed in a frame set on a gentle hotbed. The soil ought not to be kept very dry at any time, either before or after the cuttings are rooted; a little shade should be given in bright weather, and a small amount of air on the least signs of damping off. When well established the plants are best kept in cool frames, pits, or greenhouses, where they will remain cleaner and healthier than if wintered among a variety of other plants in heated houses. They will stand a little frost better than much fire heat.

Heliotropes.—These have done surprisingly well this season, and ought to become more popular than ever for bedding out purposes. If stock plants are needed it is advisable to make a number of young shoots into cuttings, and strike these much as advised in the case of Verbenas. They are not nearly so hardy as Verbenas, and can rarely be wintered in cold frames or pits, but can be kept on the shelf of a well heated greenhouse. The surest way of securing plenty of strong cuttings in the spring is to grow a number of plants in 5-inch or 6-inch pots, these flowering in the autumn in a greenhouse, or nearly up to mid-winter in gentle heat. After being rested for a time they may be re-started in a forcing house, and will soon produce abundance of cuttings.

Ageratums.—Much that has been advanced concerning the Heliotropes also applies to Ageratums. The latter, however, do not produce cuttings so freely at any time, being much the most floriferous. Soft flowerless tops, if these can be procured, soon strike root in gentle heat, and the plants thus obtained should be potted off singly and kept steadily growing throughout the winter. A few old plants kept in pots sometimes do good service, and a few that are not so profusely flowered as the rest may be lifted from the ground later on. A stock of plants may be most easily raised from seed, but these are not of such good habit as those struck from cuttings.

Lobelias.—Seedlings of these have done better than plants raised from cuttings or by dividing old plants, the latter being of the most dense habit, and therefore the first to damp off in very wet weather. Seedlings, though very much better as regards habit of growth and freedom of flowering than they used to be, do not equal struck plants of named varieties. The surest method of obtaining plenty of cuttings in the autumn is to put out a few plants each season in the kitchen garden, and these not being allowed to flower are certain to produce plenty of strong tops which strike readily in gentle heat. A considerable number of cuttings may also be obtained from the flowering plants this season, and these may be struck and treated in every respect similarly to Verbenas. Seedlings are more easily raised now than in the spring, when so many other matters require attention. Seed should be sown thinly on the surface of pans filled with fine sandy soil, this being moistened prior to sowing the seed. Set the pans in a cold frame, pit or handlights, cover closely with squares of glass, and shade from bright sunshine. The soil whenever at all dry should be carefully moistened, preferably by immersion in a tub of water, and the seedlings will require plenty of air to prevent their damping off. In this manner a capital lot of seedlings will be available for pricking out next spring, and which will require no heat to keep them growing strongly.

Various.—Alyssum or Koniga maritima cuttings may be struck in gentle heat, and if need be Fuchsias, Iresines, Alternantheras, and Coleuses may also be struck now for stock purposes. Shrubby Calceolarias, Violas, and Gazanias need not be attended to till October, late-struck cuttings being the most easily wintered.

KITCHEN GARDEN.

LETTUCES AND ENDIVE FOR WINTER.—Where salads are valued in winter Lettuces and Endive must always form an important part of them, and attention should be given to them before the season is too far advanced. Some varieties of Lettuces will grow a little throughout the winter, but so little that it would never do to trust to small plants coming on during that season, and they should be a good size before November. Indeed, we have had them almost full sized by that time, and kept them on all the winter. From the seed advised to be sown some time ago the plants will now be several inches high, and now is the time to take them in hand. Do not draw them all up from the seed bed, but merely thin them and allow a crop to remain. These will gain maturity before those that are transplanted, but the thinnings should all be planted elsewhere, and they should be planted in two or three places. If some of them are placed along the bottom of a wall or hedge where they can have a little shelter they will do well. Plant others on a sunny south border, some in open frames, or in positions where frames can be placed over them, as, let the weather be what it may, there will then always be a supply of Lettuces and Endive. Do not pamper them at first, as the more robustly they can be grown now and during the next two months the better will they be able to bear severe weather. Plant about one foot apart each way, and only in moderately rich soil,

as sturdy growth is of more importance than having huge heads before the severe weather or short days set in.

PLANTING SAVOYS.—It is now late to plant winter Greens, but Savoys of the Tom Thumb type may still be planted to be of service in winter. We have now some vacant quarters in the garden, and Savoys are being largely planted, as we do not approve of unoccupied ground in kitchen gardens at any time, and these Savoys will be valuable by Christmas and long after that time.

LEeks FOR SPRING.—Very often Leeks for spring are planted too early. When half or nearly full grown now they will have lost much of their value by March, and it is generally at that time that they are in demand. After a severe winter they are most welcome in the months of March and April, and we advise all, especially small garden owners, to plant extensively now for the demands at that season. Open drills about 4 inches deep and 15 inches apart, and plant in these at a distance of 10 inches. Throughout the winter the soil on the sides of the drills will fall back, and this will blanch the stems sufficiently to make them acceptable.

TOMATOES IN THE OPEN AIR.—We have frequently advocated the cultivation of Tomatoes in the open air, and those who have followed our advice for the first time this year may feel disappointed, as this is without exception the worst season for open-air Tomatoes we ever knew. It is an exception, not the rule. The plants have refused to grow as they ought, and as for the fruit it is scarce, poor, and almost a failure. The only ripe fruit we have had in the open air during August was from plants plunged in pots and trained up a south wall. What September may do for others we cannot tell, but we have ceased to depend on the weather this season, and surplus lights from the frames are now being placed over the plants growing against the walls. These will draw the heat, keep the rain from them, and place them so much on the same footing as the plants under glass that we hope ripe fruits may be secured by October. Some such assistance as this is the only way of securing open-air Tomatoes this season, and no time should be lost in affording them protection. Do not stimulate them to make superfluous growth; be satisfied with small fruits, and keep them quite clear of the shade of the leaves. Of late we have been gathering many fine Tomatoes from plants under glass that have not been allowed to carry half so much foliage as is generally seen on Tomatoes. Shade does not agree with them in any position.

LATE PEAS.—Like many others our late Peas always suffer from the depredations of birds, particularly sparrows. They destroy the pods almost as fast as they fill. There is no use in trying to frighten the birds, but if the crops can be netted they will be safe. Indeed, this is the only mode of preserving them, and we advise all late Peas to be netted as soon as possible. If the nets can be placed on when the plants are in flower so much the better, as we have known the pods to be injured before there was any Peas in them, and very late Peas are so valuable that all attention possible should be given them.

AUTUMN WEEDS.—Many things have failed to come to the highest maturity this season, but weeds are not amongst these, as they have grown enormously and in multitudes. In fact it is a "weedy year," and as "one year's seed" undoubtedly produces "nine years' weed," efforts should be made during September to root them up and clear them away. If the weather is dry this may be done by hoeing and raking; if wet, hand-weeding must be resorted to. Some may think so long as they can see the crops fairly above the weeds that no harm is being done, but this is a mistake, and a weedy garden, in winter especially, is no credit to its owner.

MATERIAL FOR MUSHROOM BEDS.—Collect all the horse droppings that can be procured and spread them under cover to dry previous to making up the Mushroom beds. Only the longest straw should be shaken out, and the heap may be turned over every other day to allow the superfluous moisture to escape.

PLANT HOUSES.

Abutilons.—Strong cuttings of soft wood may now be inserted singly in small pots; these will root quickly in the propagating frame if kept close and shaded from the sun. As soon as they are rooted expose them gradually to full sunshine, and grow them in an intermediate temperature. When the small pots are full of roots place them into 4 and 5-inch. The compost, consisting of loam, sand, and one-seventh of decayed manure, should be pressed firmly into the pots to prevent the plants making a soft rapid growth, and if properly treated should not be above 9 inches or 1 foot high by the time they commence flowering, and are ready for the stove or any other moderately warm structure in which they may be required. When once good plants are produced they must have sufficient warmth to keep them growing slowly or they quickly cease flowering.

Bougardias.—Where these have been planted outside and are intended for pots, lifting and repotting now need attention. Lift the plants with good balls of roots, and all the loose soil carefully worked from amongst them, so that they may be placed into pots of a convenient size. When grown on this principle it is often necessary to use larger pots than when they are confined to pots the whole season. After potting place the plants in a shady position, water liberally, and syringe freely until they become established. The past season has been of the worst possible description to ripen the wood, which is important if they are to flower freely. When the wood is only half-ripened trusses are frequently only produced at the ends of the shoots, and even then they are small. When well ripened they break freely after the removal of the terminal truss and flower on short growths from every joint. When

the plants are established place them under glass and gradually expose them. When the plants are intended to occupy side or central beds in houses lift and place them moderately close together on the border, filling in between them with loam and leaf soil, one third of the latter may be used. Give a good watering, and apply light shade for a few days until the plants will bear exposure to the sun without flagging. Encourage young plants in 4 and 5-inch pots from cuttings to complete their growth. Give them an application of artificial manure to the surface of the soil. Clear soot water will do them good and insure the foliage preserving a dark green instead of a light sickly hue.

Solanums.—Those planted out have not set well, only a very limited number having berries sufficient to render them of decorative value. Those kept under glass or confined at their roots in pots have done well in spite of the weather, but they are in a backward condition. Those from the outside may be placed under glass to bring them forward more rapidly. Supply water liberally, giving clear soot water and stimulants to keep their foliage green and healthy. Once they are allowed to suffer by the want of water or from exhaustion the foliage will soon turn yellow. In this condition *Solanums* are worthless for ornamental purposes. Well berried plants are highly ornamental when their foliage is of the darkest hue, and this can be attained by liberal supplies of water and judicious feeding.

Lilium lancifolium.—This Lily is very liable to be attacked by aphides when grown in pots for flowering indoors. The foliage should be kept clean by slight fumigations. After they have flowered the plants must not be neglected, or disappointment another year will follow. When placed outside the soil is liable to become too wet, and serious injury is the result. Place them in a cool airy position, and supply water carefully until the stems die naturally. The varieties of *L. lancifolium* do remarkably well in pots under good culture; they increase rapidly and attain great strength.

Chinese Primulas.—Admit abundance of air at night when the weather allows as well as by day. Protect them from bright sunshine, but be careful not to overshade them. If drawn up weakly by over-shading or too close an atmosphere, they will not flower half so profusely as dwarf sturdy plants, and in addition they are liable to go off during the damp dull days of autumn and winter. The earliest plants may have clear soot water, and may be allowed to come into flower if they are needed for the conservatory early in October. If not, remove the flower truss directly it is visible. Pot later plants as they need it. Those for late spring flowering should be placed into 3-inch pots.

Pinks.—The old common garden variety is very useful for forcing in 4 and 5-inch pots. Insert thickly well-developed cuttings. Water and place them in a cold frame, and nearly every one will root if shaded from the sun for two or three weeks. Year-old plants may be lifted from the open borders and potted, while good bunches may be placed together in boxes for forcing when the flowers are needed only in a cut state. They must be established before winter sets in.

THE BEE-KEEPER.

PREPARING FOR WINTER.

THOSE bee-keepers who have acted on the instructions given at different times will find that their stocks are now in a proper condition for going into winter quarters, and that in the spring the result will be favourable. But there are some bee-keepers who have not paid proper attention to the various requirements of their stocks, and to these we earnestly appeal, in their own interests, to do what must be done as quickly as it may be done. This has been a phenomenal year, and as a consequence uncared-for stocks are in a precarious state, so much so, that unless great care is taken at the present time, a greatly increased winter mortality will be the inevitable result. It is not our intention to attempt, by frightening lazy bee-keepers by holding up before them a picture of future loss, to induce them to take the proper steps for remedying former neglect, because we have no pity for bee-keepers who are enthusiastic in good seasons, and indolent procrastinators when their lot falls in a bad time; but it is a duty owing to those who err from want of thought or ignorance, to impress upon them the necessity for at once overhauling and attending to all stocks which are expected to live over the next six months and prosper.

It is said sometimes that stocks may be put into quarters too strong in numbers, and this may sometimes be the case. Over-population means a greater consumption of honey, and every ounce consumed by what we may term the surplus bees is a loss to the bee-keeper. But even here we may think with reason that the

larger the population the less amount of food need be consumed in order to produce the necessary amount of heat; but it is not necessary to pursue this line of argument further, because we find that in practice not one stock in a hundred has anything approaching to a surplus population at the end of September. On the other hand, very many stocks are undoubtedly most disastrously reduced at that period, and unless there is an augmentation in numbers, such stocks will not give the results that should be obtained from every stock in a good season. There are exceptions, but these prove the rule.

Driven bees may now be purchased at a low rate, in fact "A Lanarkshire Bee-keeper" informs us that they are a drug in the market. Here, then, is a chance for the bee-keeper who has weak stocks. Such a one should purchase driven bees sufficient to bring up the population of each of his stocks to a proper strength, and in making the purchase he may bear in mind that at the end of September a pound of bees will contain far more young, and consequently valuable bees, than will the same quantity bought at the present time.

No contraction of hives can be allowed. All surplus cases may of course be removed, but the brood nest should in no case be contracted at all; indeed stocks winter remarkably well with a case of empty combs left over the brood nest all through the winter, and the mortality in such stocks was last winter comparatively small. If stocks are strengthened by the addition of driven bees and fed up to contain some 25 lbs. of sealed food they may be wintered successfully on many principles provided that they are kept dry. Great heat is not essential to successful wintering, dryness is; warm coverings are useful, but it is no advantage to wrap up a stock until it resembles an old lady afflicted with rheumatism. We suspect that winter flights on unsuitable occasions are often caused by too much coddling in the covering arrangements, the temperature rising to a great height when the sun shines on the exterior of the hive, and the covering on the top preventing the heat from escaping raising the temperature, thus making the bees uneasy and ready to fly on days when it is dangerous for them to stir from home.

A single thickness of ticking and one pad of felt surmounted by a case containing some 4 inches of cork dust is a cheap, simple, and effectual covering for a stock; damp can then escape, and yet sufficient heat is retained to preserve the stock in a normal state. Entrances need not be very much contracted, and must never be closed except when snow is on the ground, and then only by strips of perforated zinc; and even then a board should be placed in front of the hive to prevent the sun shining in at the entrance, and thus by arousing the bees causes them to find out that they are unable to escape, with the result that a tumult may ensue with disastrous results. Some bee-keepers are, we are aware, antagonistic to thus closing the entrance, but we have never had any bad results when the above plan has been followed, while when the hive front has been shaded, but the entrances have not been stopped, considerable loss has in certain instances been the result. Hives should be well examined, and all cracks and fissures efficiently stopped by working in putty and afterwards giving a coat of good thick paint. Weeds should be cut down low, the legs of the hives examined, and everything which seems at all deficient be put in good condition, and then the bee-keeper may rest happy in the assurance that he has done all that it is in his power to do to ensure success, and that if failure does by any chance result it will be by some untoward circumstances rather than by the neglect of proper precautions.—FELIX.

NOTES ON BEES.

I WRITE near the end of August, but beyond the rise of the temperature there is no improvement in the weather so far as bees are concerned. Ten days or so more, and according to precedent, the honey season will be past for another year, and all hopes of a surplus of honey gone unless the weather greatly improves, and

that immediately. That the bees have improved their time and bettered their condition since they were set down there is no doubt, but much still requires to be obtained before the bee-keeper will be remunerated for outlay this year. Bad as this is, it is worse for the fruit and farm dependants, whose crops are in many instances either totally destroyed or much spoiled, and in others for the want of sunshine now will also be of little value to the country. It has been a year without a summer.

Queen-rearing has been almost a total failure this year. June-bred queens are still unfertilised, and later bred ones appear to share the same fate. The absence of fine days has prevented the queens flying, and very few drones remain alive. Even queen-rearing hives and those queenless or having unfertilised queens have killed them even when well fed. Never have we witnessed such an abnormal state of matters. It is now five months since I sowed Sweet Peas, and three blooms have only as yet appeared. A spike of Wallflower having about twenty-four blooms took three months to expand twenty florets.

Matters are gloomy in the extreme for both agriculturists and bee-keepers for another year—soured and weedy ground for the one, while the other has either to purchase young queens or to keep old ones, which do not give satisfaction. To manage the latter properly for another year is in the first place to prepare for winter as early as possible without encouraging breeding in any way and to have as many bees as possible. In the second place the bees must be kept steadily breeding, no falling back when once begun; and when full of bees swarm artificially if they do not incline to do so naturally. Wherever an aged queen is about to be superseded by a young one, if she does not leave the hive voluntarily or with a swarm she will be killed. Thus the hive, with all its population, may be entirely lost to the bee-keeper through an accident to the young queen; whereas with a swarm off it is always valuable (if the weather is fine), then a second swarm and the old stock there are two chances of both doing well, and if fertilised in due course will in six weeks be as strong as any hive need be. If a nucleus be formed and the queen mate it may take the place of the old queen of the prime swarm. Thus three good hives will be had, where otherwise there might have been none, and for those who have an extended season the system is the best to pursue.

My strongest hives at the Heather are early swarmed old stocks, or those I joined young fertilised imported Carniolian queens to. I may here state that these imported queens display great mildness of temper, being their usual habit, very unlike those I had from an English dealer, who supplied me with queens as Benton's, but who never had queens from him. The bees of this race are vicious, and the drones are in some instances yellow, proving that they are crosses (probably with Syrians), then bred back to a colour approaching the true type of Carniolians.

THE BEST HIVE IN CREATION.

Although the above name appears ostentatious, I fail to see it is so, because it embodies within itself every good feature a hive can possess. It is a thoroughly protected hive, and can either be moved about as it is, or in a few minutes converted into a hive occupying the least possible space superficially with the greatest amount for breeding and storing purposes, upon the most approved principle, while for queen-rearing and manipulative purposes it is excellent and unsurpassed.

Each division can be drawn out, examined, and returned without killing a single bee, and all this, too, when one or more tier of supers are on. In another article I will give details, so that any amateur with but few tools will be able to make, and as useful as if made by the best tradesman.

PAINT.

I have about half a dozen queries regarding painting hives and the colour. As the weather has been unfavourable for that work, a dry spell coming should be taken advantage of. I will therefore answer these in a general, and not a special manner. As to the colour, this depends altogether upon the taste of the individuals interested. Light colours throw off the heat of the sun, while dark colours absorb it and shrink the wood more. Mediums are often in this, as in other things, best. For hives a light fawn is a pleasing colour, but as bees recognise colour readily, a device of different colour is advisable to be painted on each hive where the wood is exposed; where it is not, a different coloured cloth is advisable. No matter what colour the outside woodwork is to be finished, the priming or first coats should be of genuine red or whitelead ground with raw oil. No boiled nor any dryer whatever should be used, and proprietors should not trust tradesmen to do as they wish, but see that all outside work be painted as I have stated. Genuine red lead is the best for resisting oxydisation on either wood or metal, and it and raw oil sink into the wood, tending

to its preservation, which boiled oil does not. For stone, raw oil of itself is a good preservative.

TARRED HIVES.

I am also asked if tar is injurious to bees. The idea that tar or tarred receptacles are injurious to bees is simply erroneous. There is nothing bees are fonder of sipping water from than tar barrels. I have the inside of my double-eased hives well tarred, and the bees do well in them, while it prevents dampness inside, and the ventilating floor carries it away. In close, well-made, double-eased hives, when not painted or tarred inside, the moisture passes from the inner to the outer ease, and paint does not adhere well, and rot is inevitable. Double-eased hives are ill adapted for bee-keeping, both as regards eluminess, and are unhealthy for the bees.

COMBINATION HIVE.

I have a letter taking me to task for recommending the tiering hive, advocating the "Abbott Combination Hive." The paper to which I am directed I do not read, nor do I agree with my anonymous correspondent in all he says. One thing, I do, however—viz., that the old, and ought to be obsolete, "Combination Hive," is the best non-swarming hive extant, because of no less than twenty I have seen this year the bees had all died in them. His other remarks I cannot comment on, as like all anonymous letters it was burned. I am prepared to discuss any question whatever on bees submitted in an honest and straightforward manner, and such only will meet the attention and approbation of—A LANARKSHIRE BEE-KEEPER.

I have letters containing numerous queries to which I have been unable to reply to, but will do so as early as possible.

TRADE CATALOGUES RECEIVED.

Messrs. John Laing & Son, Forest Hill, London, S.E.—*Catalogue of Bulbous Roots, Fruit Trees, &c., 1888.*

Wm. Thomson & Sons, Tweed Vineyard, Clovenfords.—*Vine, Plant, and Vegetable Manure; List of Testimonials.*

Barr & Son, 12 and 13, King Street, Covent Garden, London, W.C.—*Catalogue of Bulbs and Daffodils for 1888.*

Société Anonyme L'Horticulture Internationale, Brussels, Belgium.—*Catalogue of Orchids and New Plants, 1888-1889.*

Thomas Davis & Co., Wavertree, Liverpool.—*Catalogue of Bulbs and Flower Roots.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Exhibition Roses (Curious).—Your explanation is conclusive, but, as you intimate, the facts of the case could scarcely have been anticipated. If you are not able to consult the volume for the last half of 1887 we will send you the number in question if it is still in stock and you will send us your full postal address.

Wintering Amaryllises, Begonias and Gloxinias (Ardwyn).—Seedling Amaryllises are usually wintered in the pots, boxes, or beds in which they are raised, gradually reducing the water supply at this season, and when the leaves die giving little or no water in the winter, though the soil is scarcely kept as dry as dust. They are safe in a temperature of 45° to 50°. Many large growers of Begonias and Gloxinias store the tubers in large pots or boxes of pine sawdust, this keeping them sound, and is said to render them comparatively safe from mice. They are also kept in nearly dry cocoa-nut fibre refuse, in about the temperature above named for Gloxinias, but it may be lower for Begonias.

Levelling Ground for Cricket (F. L. D.).—To level a piece of land 40 yards by 40 yards with a fall of 2 feet from one end, the "width being about level," about 500 cubic yards of soil will be required; but why not make the ground level itself, and so save the cost of carting, &c.? It would be more economical, and the work well executed a much

better ground would be formed for playing the popular game. It would be very inconvenient to have all the slope at one end. The cost for lifting, levelling, and relaying must of necessity depend upon the nature of the ground and the manner in which the work is done, with the value of labour in the locality. The cartage of the soil would be worth about 1s. per cubic yard.

Transplanting Hollies and Conifers (W. K.).—The weather being mild and moist, from the middle of September to the early part of November is a good time to plant Hollies. The chief cause of these evergreens failing is the careless manner in which they are lifted, and exposure of their roots between lifting and planting to the drying influence of the atmosphere, which destroys their fibres; indeed, many shrubs, from the exposure and dryness to which they are subjected, are nearly dead when planted. Hollies also transplant safely during moist weather in April, just when they are beginning to grow, which varies with the season. Autumn planting is, however, most successful. What suits Hollies also favours the transplanting of Conifers, early autumn or late spring being most suitable.

Writing and Spelling (Bothyite).—You ask a question not easy to answer categorically, because there are degrees of badness. You want to know "whether bad writing and good spelling is a worse combination than good writing and bad spelling." We have a fair share of both, but prefer the former, always provided the bad writing represents good grammar. Some of the most highly educated persons and talented authors are what you would call "bad" penmen, and we cannot pronounce them good, but their correct method of expression disarms hostile criticism, but errors in spelling simple words almost look worse when the handwriting is good than when it is bad. We cite just one sentence from a very neatly written letter in which there are three words out of nine so grossly misspelt as to appear little less than hideous—"The gardener his appointed steward over the holt estate." We venture to say the gardener would not have been appointed steward if he were capable of making such blunders, no matter how good his writing might be.

Perennials for Flowering in August, September, and October (W. R.).—Your soil being light and dry, mulching and watering must play an important part, otherwise the growth will be poor and the flowering correspondingly unsatisfactory. Of Asters, *Amellus*, *bessarabicus*, *dumosus*, *formosissimus*, *grandiflorus*, *Novæ Angliæ* and var. *rubra*, *Novæ Bælgæ*, *polyphyllus*, and *tubincellus*. *Alstroemerias aurea*, *pergrina*, and var. *alba*, *peruviana*; *Anemone japonica*, and *A. japonica alba*; *Asclepias tuberosa*, *Campanula Hendersoni*, *Chelone obliqua* and var. *alba*, *Coreopsis lanceolata*, *Erigeron speciosus*, *superbum*, *Eryngium amethystinum*, *Francoa ramosa*; *Fuchsias corallina* and *Riccartoni*, *Funkia grandiflora*, *Gillenia trifoliata*, *Harpalum rigidum*, *Helianthus multiflorus fl.-pl.*, *Hypericum nepaliense*, *H. triflorum*, *Leucanthemum maximum*, *Malva moschata alba*, *Eriogonum speciosum*, *Oxalis floribunda rosea*, *Pentstemon labrosus*, *Pyrethrum uliginosum*, *Rudbeckia Newmanni*, *Salvia patens*, *Schizostylis coccinea*, *Sedum spectabile*, *Senecio pulcher*, *Solidago virgaurea nana*, *Tritoma var.*, *Zauschneria californica*, *Gaultheria candicans*, *Lilium auratum*, *longiflorum Harrisii*, *speciosum (lancifolium) var.*, and *tigrinum splendens*. Chrysanthemums of the early-flowering section would do well if mulched and watered. *Souvenir d'un Ami*, *Fiberta*, *Lyon*, *Precocité*, *Madame Desgrange*, *G. Wermig*, and others. They are very effective and useful for cutting.

Alternanthera Failures (C. E.).—*Alternantheras* are essentially heat-loving plants, and the present season has been most unfavourable to their growth, failures being general. They rarely form much fresh strong growth after being planted, but the stunted shoots produced are invariably the most highly coloured. The best effect is produced by putting out quite small plants very thickly in the first instance. Strong plants may look well for a few days, but when the broad or fully developed leaves fail, which they very soon do, there is nothing to take their place, for some time at any rate, and a failure may be the result. Not only are *Alternantheras* very much smaller than when first put out, but *Coleuses* and *Iresines* are not much better. *Alternantheras* cannot well be dispensed with, there being no substitute sufficiently dwarf and richly coloured. *A. paronychioides aurea* is the most delicate, and scarcely so bright yellow in colour as a good strain of *Golden Pyrethrum*. *A. versicolor* is more robust, and with us is looking fairly well. *A. paronychioides magnifica* is a great improvement on the old form, and does not often fail. *A. amabilis latifolia* is richly coloured, and one of the best for carpet bedding. You appear to have well prepared the beds, and in all probability if smaller plants are put out more thickly, or as close together as they need be at the right time next season, there will be no failure. In any case it is advisable to keep a few plants in boxes ready for any emergency. These, if needed, can be dibbled among those first planted, or they can be kept as stock plants for propagating purposes.

Gesnerias from Seed (J. E.).—The time at which the seedlings flower depends on the suitability of structures for growing them and the skill of the cultivator. They are raised and grown as follows:—Sow in February or March on the surface of a light, sandy compost in a warm stove and moist atmosphere, and as soon as the seedlings are up, and the plants have attained a leaf or two, transplant them thinly in light free soil in shallow pots, and let them grow there during the summer. Allow them to go to rest in the autumn, and keep them in the same pots through the winter, giving but little water. As soon as life appears again in the spring pot them off singly into small pots, watering and repotting as

may be required; but it is more than probable they will not flower till the second year. Light fibrous loam, turfy peat, and half-decayed leaves in equal parts, with a due portion of sand, well mixed, but not sifted, form a suitable compost. To have a succession of bloom pot a portion of the tubers in January, and place them in a temperature of 60° to 80°. Pot a second batch about the middle of February, and another towards the end of March. These will supply flowers for several months. Put them in pots according to the size of the bulbs; keep them regularly watered, but never very wet. They may be syringed occasionally previously to flowering, but not much, for the leaves are so woolly that they hold moisture too long if syringed severely. When the blooming season is over they may be set out of doors during summer, but should be sheltered from heavy rains. They will then gradually go to rest. All that they require in the winter is to be kept in their pots in a place where neither frost nor wet can reach them; yet the place should never be below 45°, nor above 55°. If the cold is much lower they will be apt to rot, and, if higher, to start into growth.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Hopeful*).—The Grapes are certainly not ripe, and on that account we cannot speak positively as to the variety, but suspect it is *Alnwick Seedling*. They will be much better in a month's time. The shape of the berries varies somewhat, and we have seen some more oval than those you have sent. (*Colden Common*).—As has been many times stated, though you do not appear to have seen the intimation, Peaches cannot be named without good leaves of the trees are also examined, as the glands on them are an important factor in the case. It is quite essential also to know whether the flowers are large or small.

COVENT GARDEN MARKET.—SEPTEMBER 5TH.

THE soft fruits being now over, our market is very quiet, Plums and Apples coming very short.

LANDLORDS' FARMING.

MICHAELMAS, always an important time to all connected with agriculture, has, under the depression, acquired much more importance, especially to the landlord and his agent, for it is indeed seldom now that the term passes by without one or more farms falling in hand, and what to do with such farms becomes a serious question—altogether one of ways and means, only to be resolved satisfactorily when enough money is forthcoming to enable the agent to take up the farm and bring it into a high state of cultivation. No light matter is it to undertake this work, for in nine cases out of ten the land is "farmed out" in the full sense of the term; poverty stricken, foul with weeds, and very likely requiring re draining. Under such unfavourable conditions, combined with low prices for farm produce, the work of reclamation is beset with difficulties, which, if not positively insuperable, are not to be overcome in a single season, except at a ruinous outlay. Under ordinary circumstances we do not recommend such an outlay, but rather to spread out the work over two or three years, so that the farm may at least be rendered self-supporting after the first year. For with farm after farm falling in, cautious expenditure is forced upon us, and we are bound to do all that is possible to curtail expenses.

Now we often hear the assertion that landlords' farming is not only unprofitable, but is positively ruinous; and it has become no small part of the work of an estate agent to prove to demonstration that such assertions are false. We go further than this, and accept the challenge thus given, striving by every means in our power to prove that when once poor farms have been restored to a high state of fertility they become so profitable as to render it desirable to retain them in hand, as affording returns upon outlay altogether superior to the rent to be obtained from a tenant.

In order to do this, judicious expenditure must be combined with rigid economy, so that enough money may be invested in the farm, and all fanciful or needless outlay avoided. We know a landlord with several farms in hand who will allow no Wheat to be grown upon any of them. Oats take the place of Wheat, and are not by any means a full crop this year. A certain loss upon such landlord's farming is inevitable, yet such risk of loss might have been avoided if the land had been in a suitable condition to yield a full crop of really fine Oats. It still answers to cultivate a fair proportion of most farm crops upon any farm with soil of sound staple if only the culture is really sound, but it does not answer to indulge in speculative crops or to venture far after novelties of any sort. The cultivation of Oats as a substitute for Wheat on English farms is certainly a novelty which could only find its justification in a paying crop. By this term we mean a crop of at least 80 bushels per acre, which quantity we have grown, but we know other farmers who by high cultivation and the use of select seed of improved sorts claim to have grown as much as 116 to 121 bushels of Oats per acre. Well done! say we, for that is the way to meet hard times. Grow more and better crops, and instead of giving up Wheat-growing let us see if we cannot get more grain and straw out of every acre of land.

Very desirable is it that landlords' farming should be so good as to afford an example to the tenants of the best way of doing things. But for it to be the best way it must show a fair margin of profit, that is the true, safe, and final test; and when a landlord or his agent can show the tenants how to get more out of the land their mutual interests will be advanced, a feeling of confidence will be created and fostered, and the landowner will be held in honour as the true friend of his tenants.

It is doubtless pleasant to see a farm in the landlord's hand that

is a model of what farming should be in every detail and feature. But in these times we cannot afford expenditure upon mere appearance, and although it is an agreeable sight when every fence and hedge are in perfect order, we cannot advise our readers to expend money upon them beyond certain limits. By all means keep cattle and sheep fences and the boundaries of a farm sound, but on arable land we are getting rid of all superfluous hedges and ditches as fast as we can, taking especial care to put down large drains in every ditch beforehand.

(To be continued.)

WORK ON THE HOME FARM.

Dull unsettled weather still retards the ripening of the corn, but most of the Wheat is now ready for the reaper. Much is cut and is in shock, and a little is in stack. Needy farmers whose calculations are altogether upset by the late harvest have another trial in having to wait for the corn thrashing, soft Wheat being practically unsaleable when brought as it now is into competition with hard dry foreign corn. Owners of hop kilns are advised to turn them to account for drying Wheat, and we have known maltings turned to account for the same purpose, an equal quantity of damp grain being mixed with the dry grain on the barn fl or immediately it is brought from the kiln. It is left for a day or two after the mixing, then passed through a winnowing machine before it is put into sacks for market.

Barley mowing has not yet become general, for it ripens very slowly. Two or three weeks of fine bright weather would enable us to save it in fair order, but it is already so much discoloured that it seems almost hopeless to expect a really fine malting sample this year. Where the Barley is beaten down there is a second growth of green patches that is a lamentable sight, for wherever such patches occur the Barley is spoilt. The best crops of Peas are those which were sown early in spring; they have podded well, and likely to be saved in good condition. Later crops have a few full pods, and many half full. The lower part of the haulm is rotting, and there is nothing for it but cutting the haulm at once and trying to ripen and harvest it. This is done gradually early in the day before other corn is sufficiently dry for reaping. Of Beans the winter crop is excellent, but spring Beans have made a remarkable growth fully 5 feet in height, and many of the upper pods are abortive. On the whole we have crops of average abundance, but all are exceptionally late, and the weather so far has been unfavourable for saving them. We still hope to be able to do this, and every arrangement has been made for prompt action if the weather clears. All depends upon this, for without fair weather our best efforts are liable to failure, and the waiting for the much-desired change is both tedious and disheartening.

OUR LETTER BOX.

Gorse as Cattle Food (J. J. W.).—The clippings of Gorse fences are sometimes used as cattle food, and the sloping banks often found in hilly districts as well as the banks of railway cuttings may be turned to account by the growth of Gorse. One of the reasons why Gorse has not attracted more attention as food for stock is in consequence of the difficulty of reducing it into a state fit for food, by breaking down the prickles and points on the stems of the plants. Analyses by various chemists have been taken, but that given by Mr. Lawes and Dr. Voelcker in comparison with other food is the most important. As follows:—

Name of Food.	Flesh-formers.	Fat-formers.	Name of Food.	Flesh-formers.	Fat-formers.
Forze or Gorse	3.21	9.34	Swedes	1.94	5.93
Cabbage	1.63	5.96	Carrots	0.60	10.18
Kohl Rabi	2.75	8.62	Common Turnips	1.80	4.44
Mangold	1.54	8.60	Clover hay	4.27	9.14

REMARKS.

26th.—Fine, with frequent sunshine in morning, showery afternoon, fine night.
27th.—Fine and generally bright morning, cloudy afternoon, spots of rain in evening.
28th.—Wet all day, with strong wind at night.
29th.—Fine bright morning, showery afternoon.
30th.—Fine and generally bright morning, heavy rain with lightning and thunder at 2.30 P.M. and showery after.
31st.—Bright and fine throughout, but cool.
1st.—Fine bright day, spots of rain in evening.
A cool and wet week, but with a good deal of sunshine between the showers. During the slight thunderstorm on 30th 0.180 inch of rain fell in four minutes.—J. J. SYMONS.

THE FRUIT REVIVAL.

AS sure as the autumn comes round the attention of cultivators is directed to the subject of tree planting with the object of providing a fuller and better supply of home-grown fruit. That object is a most important one and demands the best efforts of all who can share in its fulfilment. What we have long and frequently urged is being more and more recognised—namely, that owners and occupiers of land in this country should no longer remain content to allow cultivators three or four thousand miles away to have so large a share in furnishing British markets with hardy fruit and taking therefrom so much of British gold.

The lethargy of landowners and leaseholders in respect to fruit culture is remarkable. They appear as a body to have shunned rather than encouraged it. It is true there are exceptions, but they are only just sufficiently numerous to prove the rule. The orchards of this country are, broadly speaking, a disgrace to the nation. No doubt improvement is apparent in some districts, and many acres of land are now occupied with thrifty plantations; but all the same an overwhelmingly greater area is encumbered either with worn-out trees or varieties that cannot compete successfully with the well graded importations of fruit, especially Apples, from other lands. There is only one certain and reliable way of limiting those importations, and that is the natural one of growing more and better fruit at home. Supplies can no more be prevented reaching markets that are open to them than water can be prevented flowing down hill; and in these days purchasers do not stop to inquire from whence comes the produce they buy, and that which best pleases the eye and suits the pocket finds the readiest sale. It was probably always so. It is not in human nature to prefer the relatively dear and inferior to the cheap and superior; but still there are persons having produce to sell who appear to desire that consumers should become patriots and make a sacrifice in purchasing their wares. This will come to pass, perhaps, when the owners of estates in the country furnish their mansions from village shops instead of from London stores. The high and the low, the rich and the poor, purchase where they think they are served the best regardless of the sources of supply, and they are quite justified in doing so. That is the custom of mankind, and it embraces fruit as surely as any other commodity.

Those persons are the best friends of their country who develop its resources the most completely, and it is through negligence, want of enterprise, trusting to chance, clinging to old ways under changed circumstances, waiting for public opinion to turn in a desired direction, and losing time in the waiting—it is this standstill policy, so to say, that has made the opening for distant competitors, who saw their opportunity and seized it; and at last there are signs that the facts of the case are recognised. A forward movement is necessary, for in reality there can be no standing still while others are passing, because the faster these go the further the resters are left behind. British landowners and leaseholders have rested too long in the matter of fruit-growing. The population has increased in a much greater ratio than have the efforts for supplying its wants with wholesome, appetising, nutritious fruit. This has not been produced at home so well as in other lands, hence the extraordinary circumstance of Apples from Michigan being sold, not in our large cities alone, but in remote country villages with land all around them, seemingly in too great abundance to be tilled, waiting for trees of the best varieties to be

planted. What can be expected from such inactivity but foreign supplies? They are simply invited by it, and they come and are welcomed by those who need them.

But the possessors of British orchards argue, "We have more Apples than we can sell, and they have to be wasted or given to the pigs. What is the use of growing more?" It is of no use, but worse than useless, wasteful, growing what is worthless. That bad habit has endured too long. The best of fruit, and not the worst, must be grown, and this never fails to find purchasers at remunerative prices when the crops are fairly good. The qualification in the last sentence implies uncertainty. This is a necessity of the case, and it is best to admit it. It is not peculiar to this country, but a contingent of other lands. If the Apple crops fail here American orchardists send us fruit. Why should they not do so? And if the crops fail there, and are full here, why should not we have as good samples to send them as they send us? The American Apple crop was light last year, the result being a decrease in our imports of nearly one and a half million bushels from the three million bushels of 1886. Large consignments of Potatoes were sent from Lincolnshire and Yorkshire last year to New York, leaving a margin of profit behind them. Some fruit enthusiasts denounce Potato-growing as ruinous, and if their random writings are to be taken seriously Potato culture would be abolished and Apples grown instead everywhere. There is room for both to be grown profitably if grown well; but if what is alleged to be unprofitable can be sent across the Atlantic to market why cannot the crop—Apples—which is, when good, certainly more remunerative, be disposed of in the same way? It is entirely a question of quality and cost of production. As to quality, when the best of American Apples have been staged with English fruit at International Fruit Shows at South Kensington and the Crystal Palace, the average merit of the collections was undeniably in favour of the old country. That is a very significant fact, and shows what can be done with a good selection of varieties and high cultivation.

As to cost of production, land is now almost as cheap here as it is in America where the best fruit is grown. The average productiveness of cultivated land is much higher here than there, as is conclusively shown by the Wheat averages of the two countries—ours being about 29 bushels per acre, theirs less than 19 bushels—and surely the better the land is for Wheat the better it must be for fruit. American summers are hotter and brighter than ours, increasing the colour of fruit; but there is the drawback of drought, and "bugs" innumerable; also of severe winters killing the trees. Labour is much cheaper with us than with our transatlantic competitors, though they possibly turn it to better account than is customary in this country, and they perhaps have the advantage in rates for the transit of fruit, brought about probably by community of effort that has resulted in a better system being established. We ought to do something for America in return for her consignments of fruit, and if we cannot yet send Apples we ought for every million tins of Tomatoes received to be able to return the compliment with as many pots of jam or preserved fruits, which are prepared here cheaper than there, and will be if sugar does not rise in price.

American cultivators are also fully alive to the importance of sorting, "grading," and the careful packing of fruit. Their consignments are marked by a much greater uniformity of excellence than obtains in the produce of home orchards. They have planted large tracts of land with few varieties of known marketable value, while the habit at home has been to plant small tracts with many varieties. In country districts the "gardener at the hall" has been entrusted with the choice of varieties when twenty, fifty, or a hundred trees have been wanted by local farmers and others desiring to grow "fruit for profit," costly mistakes having been made in consequence. More than half the private gardeners in the kingdom, however competent they may be in their calling, and no

matter how satisfactorily they may discharge their duties, are necessarily unacquainted with the demands of commerce in fruit and how best to meet them. This is no fault of theirs, though not a few have gained knowledge on the subject by reading, also by visiting the sources of supply and distribution; but all the same, safe and sound local advisers are in the minority.

An example of the unwisdom of acting on the advice of the nearest local gardener in the choice of trees for producing fruit for market can be given. Fifteen years ago a farmer, safe in his holding, planted 300 Apple trees. Not six trees of one variety can be found in the whole plantation, but in the majority of the rows there are only two and three trees of a sort. A greater blunder could scarcely have been committed. Many of the trees are worthless, and most of the fruit has had perforce to be mixed and disposed of for smashing to form the body of, or provide syrup for cheap jam. That kind of Apple-growing will not "pay," and as a matter of fact the occupier of the land in question wishes he had never planted the trees. He would, however, be foolish to destroy them, as they may yet be made profitable by grafting. That is by no means a solitary instance of the kind that could be adduced, and similar mistakes may be seen in orchards of various sizes all over the country.

A revival of interest is clearly apparent in the subject of fruit culture as a profitable industry. The great want is knowledge founded on facts, and not on individual fancies. The subject is a tempting one for sensational writers and speakers, who find it easy to show in figures that fabulous profits are at the command of all who have an acre or two of land and will plant it with Apple trees. Fifty or sixty pounds an acre are to be cleared in that way, say the enthusiasts, but they do not say when. No account is taken of the time in waiting for the harvest, nor of the certain contingency of unfruitful seasons. The Apple crop is more often under the average than above it, and it is no long time since orchards were practically barren for four or five consecutive years. It is best to be moderate in anticipation, or victims of disappointment may be created. It is enough to know that there is never a general failure of all kinds of fruit; and also to be assured that a well-conducted system of fruit culture gives a fair return on the outlay invested in it; but something besides Apples must be grown, and soft or bush fruits are more quickly remunerative, if not more permanently satisfactory to the growers.

Conferences or conventions of fruit growers have long been held in America, also on the European continent, and a great amount of knowledge thereby obtained and disseminated. Small gatherings of fruit growers and other persons interested are held periodically in certain localities in England, and no doubt serve a good purpose; but such meetings as the one held at the Crystal Palace last week, and another to be held under the auspices of the Royal Horticultural Society at Chiswick in October, are invested with a distinctly national character. The Palace Conference was a great success, the attendance being large and enthusiastic, while the papers read were worthy of the occasion and object. At the Chiswick Conference typical fruit of marketable value from various districts of the country will be represented, and the best selections of varieties for commercial purposes made by cultivators in those districts. From such conferences as these information must be forthcoming that will be of great value to intending cultivators of fruit on commercial principles.

CONFERENCE OF FRUIT GROWERS.

THE Conference of Fruit Growers at Sydenham, proposed early in the present year and previously referred to in these columns, was held on Friday and Saturday last, September 7th and 8th, in the dining saloon at the Crystal Palace. Upon the first day there was a large and representative gathering of gardeners, fruit growers, and amateurs interested in the subjects to be considered. Amongst those present were the Chairman, T. Francis Rivers, Esq.; Dr. M. T. Masters, the Rev. W. Wilks, and Messrs. A. F. Barron, J. Laing, G. Bunyard, A. H. Pearson,

Peter Veitch, J. Douglas, D. T. Fish, J. Wright, C. Ross, C. J. Goldsmith, W. Goldsmith, G. Gordon, S. Ford, A. Dean, Albert Bath, T. W. Beach, J. Willard, H. Bennett, E. Molyneux, W. Wildsmith, W. H. Ward, A. Miller, W. Pratt, R. Parker, &c., with the Hon. Secretaries Messrs. Lewis Castle and Wm. Earley.

It was decided to take all the papers first, and these were read in the following order on Friday, some modification of the programme having been necessary to suit the convenience of those who wished to be present on that day. Mr. Rivers took the chair shortly after 3 P.M., and read a paper on "Fruit Culture for Profit." Mr. Webber of Covent Garden, contributed a paper on "Packing Fruit." Mr. S. Rawson of Birmingham, and Mr. R. Smith of Yalding, Maidstone, following on "Packing, Carriage, and Marketing." Mr. Albert Bath of Sevenoaks, read a brief but pithy paper on "Land Tenure in Relation to Fruit Cultivation." Mr. Miller of Esher, and W. Iggulden of Frome, also contributing interesting papers on grafting and fruit culture, and Mr. T. W. Beach read a short paper respecting Lord Sudeley's fruit farm at Toddington, Gloucestershire.

FRUIT CULTURE FOR PROFIT.

BY T. FRANCIS RIVERS, ESQ., SAWBRIDGEWORTH.

OUR meeting to-day is, I hope, the first of a series of meetings on the very important subject of fruit culture in England for profit. Within the last few years a very great advance has been made in this direction by the force of circumstances, and not by the speeches of any one man, however eminent. When Wheat was worth from 40s. to 60s. per quarter there was no need to apply the resources of the land to any other purpose, as the price of Wheat governed the price of produce, and was amply sufficient to support the different interests depending on the land. We have now, however, to face an altered condition of affairs. The land is with us, and is as productive as ever, but the consumer no longer pays the price required by the English producer; and although it is absurd to suppose that corn is not still the ruling crop, yet all cultivators are forced by circumstances to consider whether they cannot be assisted by other crops. One of these helps or aids is undoubtedly the cultivation of fruit, which is of daily consumption, and is, or ought to be, on the table of every individual in the United Kingdom. We have, therefore, to deal with a very large subject—nothing less than a national industry, and an increasing one, the development of which enters into conflict with no British interest, treads on no man's toes, is strictly non-political, will suffer no decay but improve as the years roll on, and in which succeeding generations are quite as much interested as we are, and is a pursuit from first to last which never wearies. A man between seventy and eighty can make the superintendence of orchards both his pleasure and employment.

We have not, I think, in England held enough meetings of this kind; they are frequent enough in the United States, where fruit is an important factor in national life, and takes rank with the most advanced agriculture. In Belgium, a country which profits largely from the exportation of fruit, pomological congresses are constantly held. I have attended several, my first introduction to Belgian pomologists being at Namur in 1862, when the hospitality of the town was profuse and splendid. There can be little doubt that these meetings are of great public utility, and now that we are entering the lists and preparing to meet an enormous and increasing domestic want, it does not become a great and wealthy country like England to be anywhere but first in the race. Our climate is good, our soil so varied that we can find land for all ordinary crops. Although we are subject to cold and late springs yet we do not suffer from the extreme of heat and cold to which great continents are subject, storms which destroy the fruit, and cold which will destroy the trees. Neither is it so equable that fruit trees are exhausted by continual bearing, a condition under which eight to ten years would be the term of the natural life of the tree, conditions which would no doubt be satisfactory to the fruit tree grower, but with the inevitable result of the supply overtaking the demand, and of the usual disastrous consequence. Of this, however, we need have no fear. We must, in order to secure early profits from a garden orchard such as I propose, plant on a different principle to that of our forefathers, who have bequeathed the hoary and lichen-covered trees dear to the artist and fruit-loving boys and girls. These picturesque old trees are as much things of the past as our wooden three-deckers, and instead of the acre of grass land with the customary 108 trees often broken down by stock, and producing more wood than fruit, the modern fruit orchard must be condensed into a compact compass, give more fruit in 1 rood of land than in 2 or 3 acres of the old-fashioned style.

SOIL.—The most important part of the preparation of an orchard is, of course, the quality of the soil, and the intending planter should not

hesitate to spend a few shillings in obtaining an analysis. I attribute a great part of my success in fruit growing to the nature and qualities of the soil. An analysis made by Dr. Voelcker for Mr. Prout of Sawbridgeworth gives the following constituents of the land on his farm, mine being the same formation and closely identical. The quantities are contained in depth of 6 inches per acre—

Phosphoric acid ..	2½ tons	Sulphuric acid ..	2½ tons
Potash ..	5½ tons	Nitric acid ..	22 lbs.
Lime ..	37 tons	Nitrogen ..	1 ton
Magnesia ..	4½ tons		

I shall show presently by an analysis of fruit that the inherent qualities of this soil are vastly favourable for certain classes of fruits, and if the depth instead of 6 inches is extended to 20 inches, to which the roots of fruit trees will reach in searching for food, the aliment afforded is of inexhaustible amount. With our present knowledge of artificial manures all deficiencies in other soils may, however, be easily supplied; but I hope you will agree with me that an analysis of the soil is indispensable, and that it is necessary not to judge only by appearance, but to gain an intimate knowledge of the soil constituents. A deep rich loam is sometimes mis-leading, and trees, though apparently vigorous at first, being deprived of their requisite food will become cankered and stag headed. The cultivator must make it his business to cure this defect, which an elementary knowledge of chemistry and of the application of chemical manures will enable him to do. The position of the orchard is another important point. It is, I think, well known that frosts are more severe in low lying lands near rivers, and fruit trees should consequently be planted above the line indicated by the rising mists.

The preparation of the soil is the next point, and I will assume that a man with 100 acres of land can afford to devote one rood for the cultivation of an orchard; this must be fenced with wire netting high enough to keep out hares and rabbits during snow, as one night's visitation of these animals would suffice to destroy the growth of years and to ruin the plantation. In my own case I have sunk a barbed wire to prevent burrowing. Wire netting is so cheap that this expense is not great, and with proper care it will last for years. At all events, it must be incurred, for although rabbits may be utterly destroyed, hares will travel for miles in search of food. In Belgium in the fruit-growing districts they are altogether absent, but it is not likely that this will ever be the case in England. The land, if at all infested with twitch, should have a summer's fallow to eradicate this pest, as it cannot be easily destroyed when the trees are planted. It will grow amongst the roots, and is then most difficult to deal with. As early in September or October as practicable the rood of land having been previously dressed with some 12 or 15 tons of good farmyard manure, should be trenched to the depth of 24 inches, the top soil being kept at the top and the bottom broken up and turned over. I am convinced that this costs about 1s. 6d. per square rood, or £3 for the rood, according to the tenacity of the soil, and is absolutely necessary, as I have found from experience that my plantations made in a soil which has been frequently trenched bear more abundantly, and give finer fruit, and are more healthy than those which I have planted in holes only without moving the surrounding soil. The rood of land trenched and fenced will be ready for the reception of the trees in November, the soil being pulverised and settled. Considerable expense having been incurred, I propose to show that the planter will be able to recoup himself by the number of trees he can plant and the consequent produce. The rood of land will accommodate about 400 trees—that is, 200 trees planted 9 feet apart row from row and 6 feet apart in the rows of Plums, Apples, and Pears, and 200 bushes of Currants and Gooseberries between at 6 feet apart in the rows. The rood, therefore, will contain as many Apples and Plums as two acres of the ordinary farm orchard, and enough bush fruits to pay all rent and expenses, and will be protected from all injury from stock and game, and without such protection it is useless to plant.

SORTS OF TREES.—In my own district the Plum is the most valuable fruit I have, and it is not difficult to explain the reason of this superiority. The Plum, according to an analysis drawn out by Mr. Edmund Tonks of Birmingham, contains:—

59.21 potash.	15.10 phosphorus.
10.00 lime.	3.83 sulphur.
5.46 magnesia.	2.36 silicon.
3.20 iron.	

All of which constituents are largely present in my soil. It is one of the most valuable fruits of our domestic economy, it makes a delicious and nutritious preserve, and during the months of July, August, September, October, and even in November, it may be present daily on the

dinner table either cooked or uncooked, and I believe that certain classes of the Germans almost exist on the fruit, such are its nourishing qualities. The sort which I plant the most extensively is the Early Rivers or Early Prolific; this was raised by my father some fifty years since, and in the most disastrous seasons I have never known it completely fail. I believe this immunity to be owing to the fact that from its precocity (as I have known the whole crop gathered by the 5th August) the tree has time to recover its strength in the period of nearly eight months which elapses between the gathering and the next season's blooming. The density of the fruit is very great, as it weighs 70 lbs. to the bushel. This is against the producer, and it ought to be sold by weight. I believe that as a dried fruit it will fully equal the dried French Plums. Close to the gathering of the Early Prolific I have the Czar, a large purple blue Plum of abundant fertility; then the Sultan, and at the end of September Prince Englebert and Pond's Seedling; and beginning of October the Monarch, Archduke, and Grand Duke. I have discarded the Diamond, Reine Claude de Bavay, Reine Claude d'Oullins, Belgian Purple, as too uncertain for market Plums. For the farm orchard the interval between the Sultan and Pond's Seedling should be filled up by the Victoria, Green Gage, Gisborne's, and the Pershore, all of which are well-known market Plums, and are equally suitable for cooking, preserving, and drying, and I hope one day to see the grocers' shops continually supplied with these Plums of British manufacture. The Cluster Damson, well known for its enormous fertility; the Prune and Shropshire Damsons are also very important fruits which should find a place. The sort of tree to be planted should be what are usually called two or three years unpruned standards, the younger the better, as the transplanting causes little injury to young trees. I may here mention that the Early Rivers does not prosper in my soil when grafted on the Mussel stock. The future health of a plantation depends very much on the stocks used, and it is therefore necessary to be particular on this head.

The fruit which stands most in national importance is of course the Apple, and it seems strange that we should allow foreign nations to usurp our position in the supply of this very necessary want. In the 200 trees required for the rood I should apportion 100 Apple trees, and for a continual supply of culinary fruit Keswick Codlin, Duchess of Oldenburg, Lord Suffield, Stirling Castle, Worcester Pearmain, Manks Codlin, Eeklinville Seedling, Lord Grosvenor, Warner's King, Blenheim Orange, Baxter's Pearmain, Lady Henniker, Tower of Glamis, Betty Geeson, Dumelow's Seedling, will last from August to the end of April; of dessert Apples, Red Juneating, Irish Peach, Summer Golden Pippin, Devonshire Quarrenden, Williams' Favourite, Ribston Pippin, Cox's Orange Pippin, King of the Pippins, Blenheim Orange, Mannington's Pearmain, Lord Burghley, Sturmer Pippin, Allen's Everlasting will give a supply from June to May. On the Paradise stock all these Apples will form fruitful and profitable bushes and are all marketable Apples, and in my opinion are very much better than any Baldwins or Newtown Pippins. Some of these kinds, such as the Manks Codlin and Stirling Castle, can be planted 6 feet apart. Worked on the Crab stock, they are so fertile that they are soon dwarfed by the production of fruit. As with Plums, I should recommend trees of two or three years old being planted. Of Apples of recent introduction I have not found Mr. Gladstone so good as it was represented. It is not earlier than the Juneating, is very unequal in size, and has the unpleasant habit of being in a constant perspiration. Lady Henniker is a large and fine Apple. Peasgood's Nonesuch is very handsome and large, but does not bear so freely in my soil as the Apples I have named. The stock English Apple, the Blenheim Pippin, is a long time coming into bearing, but when fruitful always commands a high price; this and the Dumelows' Seedling would, no doubt, be valuable for cutting into chips and rings.

The analysis of the Apple differs from the Plum. There are present:—

Potash ...	35.68	Iron ...	1.40
Soda ...	26.09	Phosphorus ...	13.59
Lime ...	4.08	Sulphur ...	6.09
Magnesia ...	8.75	Silica ...	4.32

The Pear is the next in rank as an industrial fruit, but it by no means equals the Apple or the Plum in importance; indeed, during a great part of the year it is seen only on the tables of the wealthy. I have, however, had a considerable experience of Pears as standard trees. Within my recollection I have seen planted and destroyed the following sorts:—Summer Bergamot, Lammas, Passans du Portugal, Windsor, Williams' Bon Chrétien, Dunmore, B. d'Amanlis, Marie Louise, Louise Bonne of Jersey, Winter Crassanne, Beurré de Capiaumont, Beurré Bose, Comte de Lamy, Hessle, and Spring Beurré, none of which ever paid the rent of the ground they occupied. I have, however, raised three sorts of Pears which will reverse this position. These are

the Beacon, ripening the end of August and beginning of September, which is so fertile that grafted on the Pear stock it may be planted at the same distance as the Plum and the Apple; the Fertility, which is equally fertile either on the Pear or Quince; and the Conference, which is not yet introduced to the public. The two former are already well known. Of recent foreign Pears which are hardy, Madame Treyve, Souvenir du Congrès, Marie Louise d'Uccle, and Emile d'Heyst are marketable sorts; of baking Pears the Catillac is probably the best. The Pear differs in analysis from the Plum and Apple. It contains:—

Potash	54.69	Iron	1.04
Soda	8.52	Phosphorus ..	15.20
Lime	7.98	Sulphur	5.69
Magnesia	5.22	Silicon	1.49

The best class of tree for planting is the two and three years old on the Quince stock, excepting the Souvenir du Congrès and the Beacon, which should either be double grafted or on the Pear stock.

The Morello Cherry on the Mahaleb stock makes a very prolific bush. Grown in this way or trained to iron wires it may be easily protected with netting. Between the rows of pyramid or half-standard trees Currants and Gooseberries can be planted without in any degree injuring their produce, care being taken to return to the soil by chemical manure the constituents of which it is deprived by the growth and fruitfulness of the trees. By attention and occasional analysis there will be no more difficulty in doing this than in providing for the ordinary farm crops.

PRUNING.—In a farm orchard it is not necessary to prune trees severely. Pears and Apples in unfruitful seasons should have the shoots stopped in June, and should be occasionally examined and the inner growth lightened to let in the sun and air. About the end of September the shoot made after the first pruning should be shortened to four or five buds. As soon as the trees are fruitful very little pruning is required. Plum trees require as little pruning as possible, but all gross shoots should be removed when observed. The sorts of Plums I have named fruit so early that they do not grow into very large trees. In these garden orchards it is not well to allow the trees to grow to more than 10 to 12 feet. Avoid the use of long ladders as much as possible, and the consequent expense and delay in picking, which ought to be done by women and boys.

DRYING.—It is lamentable to hear of the shameful waste undergone when we have what is called a glut of fruit, and we shall hear no doubt in another paper of the proper means to be taken to prevent this loss. I have heard of tons of Plums in Worcestershire rotting because of the excess. There is no doubt that all this material could be saved and turned into food. The Persian shepherd goes out to his work provided with a bag of dried Peaches, which are so hard that he chastises his dogs, with them. The dried Misch Misch Apricot is a staple caravan food made into cakes and carried in a small compass. We pay a large sum to the French for dried Plums, and the ladies in Portuguese convents are properly employed in preserving the delicious Guimaraens Plums. The absence of sun is no excuse for our being so backward in these matters. We can and do ripen Grapes as well as the hot sun of Spain, and artificial help will serve us as well for drying fruit as for ripening Grapes.

The disastrous malady termed canker may be much alleviated by attention to the soil constituents, and in a paper read at Birmingham Mr. Tonks stated that he had removed the disease by the application of chemical manures, potash being the principal ingredient. The trees in my soil are almost entirely free from the disease, and this immunity is probably owing to the abundance of potash, which should be returned to the soil at every opportunity. The dressing applied by Mr. Tonks consists of nearly equal quantities of superphosphate of lime, nitrate of potash, nitrate of soda, and sulphate of lime. Although pruning may be carried to excess it must not be neglected, as it is desirable to grow fruit and not wood. It can be seen by measurement that much room is wasted by profitless and barren shoots. With judicious pruning this need not occur.

The Royal Agricultural Society has, for the first time, offered prizes for preparations of fruit next year. It has been a long time recognising the fact that land produces other necessities than corn and cattle. We fruit growers have done very well without this recognition, which has come a little late in the day. It is, however, a step in the right direction. The advance of pomology during the last thirty years has been quite as rapid as the advance of agriculture, and we may be certain that there is no finality. Fruit-growing, I beg leave to state, is not the handmaid, but the helpmeet of agriculture, and I believe the best interests of the land would be served if landlords and tenants would meet to discuss the conditions under which they can advance the cultivation of fruit to their

mutual advantage, and if these meetings were made public every village in England would be benefited; in time competent advisers would be provided, and as the interests are national, it is hoped that means would be found of advancing money at a low rate of interest. There can, I think, be no fear of the supply overtaking the demand, and it is certain that foreign competition would not prevail against home-grown fruit if produced in sufficient quantity and of good quality.

The production of fruit under glass requires capital and skill, and although not national is, and will become, an industry of great importance. Nearly forty years since my father proved that the cultivation of Peaches and Nectarines could be carried on in unheated glass houses with a certainty of success unknown to wall culture. The orchard house has now become an established fact. For some time before this system had been in full work the only early Peaches—that is, those ripening in July—were the Early Nutmeg, the Early Ann, the Double de Troyes, all of them almost worthless except for precocity; now, however, we have ripening the 1st July, the Alexander, an American Peach, closely followed by the Early Beatrice, Early Louise, Hales' Early, Rivers' Early York, ripening during a month in which thirty years ago there was not a Peach worth having. During the months of August, September, and part of October there can be grown a continuous series of Peaches. The advance in Nectarines is equally conspicuous, the Lord Napier beginning a supply of Nectarines of high quality in August, which other sorts continue until the end of September, and ceasing with the Victoria. With these varieties, which were certainly not available thirty years since, an orchard house will give a continuous supply of Peaches and Nectarines for four months; a house 100 by 24 feet properly managed will produce over 3000 fruits of high quality. Such a house was built in 1855 at a cost of £147, and has produced for the last twenty-five years between 3000 and 4000 fruits annually. The cultivation of Grapes is advancing in our own islands with extraordinary rapidity, and although we hear complaints of the lowness of price, we do not hear that building Grape houses is declining, a good proof that no fear is entertained of the future prospects of Grape-growing.

COLD STORAGE.—The principle of cold storage is likely to be of very great importance in the future, and experiments are now being made with regard to the preservation of fruit under the influence of cold. Now I am convinced that if a low temperature cannot be usefully applied to keeping fruit, it may be made very useful for the storage of trees, particularly of Pear trees on the Quince stock. What I have to suggest is that Pear trees on the Quince stock may be placed in pots in a cold storage in a temperature not lower than 36° Fahr., and retarded until the middle of April. By this means the blooming season may be kept back until all danger from spring frosts is past. The fibrous roots of the Quince and the slow growth of the Pear render this class of fruit tree particularly suitable for this method; and as large Pears are worth in November and the succeeding months from 6s. to 8s. per dozen, cold storage, if possible, and if room for trees can be provided, will give a handsome profit. I tried some few years since to find a system which I could employ, but I was then offered small receptacles like a miniature chest of drawers, when I wanted room for hundreds of trees. I was not then acquainted with the premises of cold storage in Leadenhall Market.

In Belgium it is customary to form clubs of fruit growers to compete at the various horticultural shows; the combination of growers enables each man to choose his own particular fruit to show with his club. These contests are very interesting, and would, I think, if carried out in England, cause much friendly rivalry, and advance the interests of pomology. I have, I am afraid, set a bad example of exceeding the time allotted to the speakers, and, if so, I must ask to be forgiven, and conclude by saying I cannot, I am afraid, hold out any hopes of creating a large fortune by fruit-growing, but it is an investment and an occupation with a more or less certain income, which will become more certain with improved means of preservation.

PACKING FRUIT.

By MR. J. WEBBER.

IGNORANCE displayed in packing and want of knowledge of the condition in which fruit should be sent to market are the principal causes of loss to the fruit grower in this country. In packing we are far behind our continental brethren, for while they study not only the condition most suitable for travelling, but even the package in which the fruit is to be sent, we frequently send it too ripe, and make use of any package that may come to hand, with little regard as to whether it is too deep or too shallow, or will hold such quantities as are ordinarily marketable.

Packing is such an important factor in the attainment of good prices for market produce that it ought to be one of the essential points in the

education of a gardener; for what is the use of growing the best fruit in the world if it be spoiled in transit? At least one-third of the hot-house fruit sent to market is depreciated in value, and sometimes rendered worthless, by bad packing; whereas, if all came in marketable condition the price would be lower to the consumer, the supply being larger, and a better result all round would accrue to the grower. Bearing this in mind, I beg to submit the following remarks as applying to London markets.

There are three golden rules to be observed in sending fruit to markets.

1st, Never send it too ripe. Peaches especially should be packed hard, as they travel better in that condition, and are rarely used by the shopkeeper till two or three days after purchase.

2nd, Never, if possible, send it for Saturday's market, as with the exception of Strawberries the retailer invariably provides himself beforehand with what he requires: Monday and Tuesday for the first part of the week, Wednesday and Thursday for the latter part. In hot weather, when fruit ripens fast, small consignments may be sent on Friday.

3rd, All fruit should be sorted into bests and seconds, and in some cases into thirds, as there are always buyers of bests, and buyers of seconds and thirds, but seldom buyers of mixed.

GRAPES.—Among hot-house fruits, Grapes being most important, as growing all the year round, claim our first attention. There are two sorts of baskets in which Grapes may be sent to market—viz., the "handle" and the "baby." The former is more useful for ordinary work and is safer, as the handle is used for lifting, and to a certain extent is a protection to the fruit in preventing other goods being placed on the top. A little packing should be placed in the bottom of the basket, then a lining of white paper. The bunches should be packed close together, shoulder upwards, and the basket tied over with a sheet of stiff paper with a label "Grapes with care" on it. Grapes packed this way will travel any distance. Special bunches travel in "handles," each bunch tied to the basket, without the centre being filled up. The latter mode is recommended in the case of special fruit only. The "baby" basket should only be used for short distances, and where a regular supply is sent, and where the railway porters are accustomed to them. It is more convenient than the "handle" for displaying in the shop windows, and shows off the fruit better. The basket should be lined with white paper and a little packing placed in the bottom, the bunches being simply laid in close together. The whole fits nicely into a hamper known as a "flat," and with the ordinary Grape label invariably arrives in good condition.

PEACHES should be packed in shallow boxes of sufficient depth to allow a good bed to lay upon and a slight layer of packing on the top. The box should contain only twenty-four best or thirty-six seconds. Each fruit should be wrapped in soft paper. A very effective way of packing Peaches, so as when the box is opened the class of fruit can be seen at once by the buyer, is to roll a double slip of tissue paper round each fruit, leaving the crown exposed. This requires a sheet of paper to be placed over the fruit before finally filling up with the packing. I know of no packing better than moss, which should be properly dried and cleansed from all grit. It is cooler and more elastic than any other substance. Each fruit should be completely surrounded with it. Next to moss is bran, but care should be taken to shake it down well and refill the box before fastening the lid, as it settles down with the oscillation of travelling, leaving part of the fruit exposed and liable to injury. Wadding is not elastic, and is too heating.

STRAWBERRIES should be packed in boxes in single layers containing from 1 lb. to 1½ lb., according to size, each Strawberry being placed in a Strawberry leaf on a thin layer of moss with only a light layer of leaves on the top. Each package of say five or six boxes should have a label "Strawberries with care, this side up" on the top of it. When the season is full on they lose value if delivered after 8 A.M., as the trade then supply themselves from the "morning gathered" delivered by the growers themselves.

TOMATOES should be packed in "handle" baskets containing from 18 to 20 lbs., and should be well coloured, but not too ripe, otherwise they are apt to split.

OUTDOOR FRUIT.—Suitable baskets for sending outdoor fruit to market can always be obtained of the salesmen. These consist of quarter sieves, half sieves, and sieves. The former hold 12 lbs., and are used for best samples of all kinds of soft fruit. Half sieves are used for Cherries, Currants, Plums, Pears, and Apples. Sieves are used mainly for Apples. A half sieve of soft fruit should contain 24 lbs., of Plums 28 lbs., of Apples from 21 to 24 lbs. Soft fruit should be simply tucked down with a sheet of paper. Hard fruit should be stuck down

with dry packing, such as hay or straw. All fruit opens better with sheet of paper covered over.

PEARS, especially early varieties, should be sent directly they can be removed from the trees. On no account should they be allowed to get ripe. The system in vogue in France is well worthy of imitation by growers in this country. The fruit is carefully sorted, in many instances into four sizes. Cases are made to contain two tiers, each tier consisting of twenty, twenty-four, thirty, and thirty-six fruits. A layer of paper shavings is placed between each tier, and one top and bottom. When the fruit is extra large and kept late in the season, cases to contain a single layer of twelve and fifteen are used. If packed in half sieves, the better sorts should be placed in layers with a little packing between.

CARRIAGE.—With regard to the cost of carriage little can be said here except that the rates, as we all know, are very unsatisfactory, little or no inducement being held out by the great carriers for the development of produce on a small scale. Special rates may sometimes be secured for regular consignments over 28 lbs., but even then there is often a difficulty in keeping the railway company to their contract. All goods by passenger trains should reach the markets by 7 P.M., so as to be ready for the next morning's trade, as if not they are seldom delivered till after the market is over, and therefore lose in value.

PACKING, CARRIAGE, AND MARKETING OF FRUITS.

By MR. SAMUEL RAWSON.

I HAVE been asked to give my views on the subject of the packing, carriage, and marketing of fruits, and as I have had many years' experience in the business, I have jotted down a few hints which I hope may lead to consideration by those who are most interested in the subject—that is, the growers of fruit. Anyone can grow fruit if he have the trees, the land, and the climate; but it is not everyone who can make the best price of it by judicious marketing, as there is much art in that. There are the picking and the packing, as well as the choice of a market and a salesman. We are all aware of the old adage, "Put the best side towards London," and know pretty well what "toppers" mean; but you may depend upon it that it is very unfair to the salesman and the customer in town to top or face the baskets of produce sent to market with a few of the best fruit, to cover the idleness or carelessness in picking. This is often the reason of many complaints of certain growers receiving bad prices, as shopkeepers, if once bit, will be very shy of buying that grower's produce again, unless at such prices as will make them some recompense for their loss on their former outlay.

In France they manage much better. Perhaps it may be said their dwarf pyramid trees, and their cordon system of growing, facilitates the picking, as there is no climbing or shaking of trees, no dropping of fruit by the moving of ladders. This I admit is a great advantage, and the fruit must be freer from bruises than ours; but does the English fruit grower ever trouble whether the fruit is bruised or not? I say no; he does not. In nine cases out of ten all he cares about is getting it off the trees and sent to market, and in many cases without even studying whether this or that sort ought to be sent first. The Frenchman does not do this. He carefully hand-picks and selects the finest of his fruit, and places it separately, either on racks specially fitted round his fruit room, or lays it thinly on straw apart from the main crops, which he offers for sale first, and, should the market prove to be brisk he will often sort his fruit two or three times, leaving only the very smallest to be sold in large packages. The others are made up in small packages marked with the number of fruit and initials of the packer. Thus one grower's packing will make double the price of another's, if his mark has become known as an honest packer; but in cases of small growers, or people who want cash at harvest time, and cannot afford to store fruit, their produce is sent into the towns. The French fruit-grower studies how he can improve his fruit produce by planting sorts that command a sale; then, by adopting small packages, and by often realising more for 1 ton of fruit than we do for 2 tons of ours. Why is this? The French do not begrudge employing labour, while the English grower growls and grumbles if he employs a few extra hands. I say labour will and must pay, and farmers would do better by employing more labour. I give you an instance.

I was in Cornwall, I think it is three seasons ago. A grower was about to send me some Apples for sale. They were early Apples, I think about a ton of Keswick Codlins and half a ton of Quarrendens. I was grieved when I saw him packing them, for both kinds were really fine clear fruit. I said, "Why did you not hand-pick these fine Codlins?" "Oh!" he said, "it won't pay; I have not time." I said, "Why did you pick the Quarrendens?" He said, "Because we could

not shake them." He was packing them in large, rough-looking, oval baskets, the class of basket generally used in that part to hold 80 or 100 lbs. He was using neither straw nor paper at the bottom to prevent the twigs of the baskets bruising the Apples. I told him that they would make more than double the price if they had been picked and were packed in smaller baskets, and advised him to go to Penzance and buy a lot of small baskets, such as are used in picking the fruit from the ground to carry to the barns. He said he would not go to the expense. I therefore told him if he would name a price for the Quarrendens I would buy them. He named a price that had been returned to him that morning for some similarly packed and sent to another market. I consequently bought the fruit, obtained some smaller baskets, had lids made for them, and packed the twelve baskets I bought from him into thirty-six of the small baskets, making thirty baskets of selected fruit and six baskets of seconds. Now the result was astonishing. I had twelve baskets sent from a neighbour of his the same day, and the thirty baskets that I had packed out of the twelve baskets made just double the price of the twelve baskets his neighbour consigned to me packed in the Cornish fashion. I thus made double the price for my trouble, with six baskets seconds to the good.

The way Strawberries are packed from that district is abominable. Though they grow good and early fruit, they are spoiled before they get to market, being packed in pound punnets, wedged into an old Orange box with a little fern between each layer. I cannot understand what this fern is for, unless it is to cook them before they come to market; for after a twelve-hours journey in one of those covered iron trucks that has become nearly red hot, after standing in the hot Cornish sun all day waiting for its freight, then to be filled with fruit that has been picked during the day, and closed up for a long ride to London or Birmingham. This fern is admirably adapted for sweating the fruit. I have used it myself for sweating and ripening fruit, but that fruit has been of the nature of hard Pears or Plums that I wanted to get up to colour. I should think Strawberries are quite ripe enough without sweating; besides, it so alters the colour and taste, and makes it so awkward for the shopkeepers to put them into paper bags, or make a parcel of one of these punnets for a customer to carry home, the juice being so liable to run on the clothing of the purchaser. My opinion is that Strawberries ought to be sent to market on wooden trays, about 3 inches deep, 2 feet long, about 15 inches wide, made to fit into each other in nests of six, with nothing over them except a lid on the top box; these trays to hold 12 lbs. They can be carried about the beds, there being a hole at each end for the handle, and to admit air, the whole six being bound by a cord; thus six dozen could be sold together. The shopkeeper could pay the salesman a deposit of 6d. each on the trays, and the shopkeeper could place the trays in his window or on his stall without necessitating his turning them out and bruising them. None but the finest fruit (unless in a scarce season) should be put in these trays. Each picker should have two vessels to pick in, one for fruit for shopkeepers, and one for jam makers or hawkers; and when Strawberries are picked free from stalk they should be put in tubs, as I have seen them sent to market ready picked in 12 lb. baskets, and a sorry plight are they in when they arrive in a provincial town, besides the loss in weight, some baskets losing as much as 3 and 4 lbs. each.

With respect to marketing, I think with extended fruit cultivation we shall want extended marketing, distribution, or manipulation, or whatever you like to call it, but it simply means the fruit grown must be disposed of in the most economical way to bring a profit to the grower. Salesmen will have to be provided with very large capital, and the convenience for preserving the fruit and vegetables in superabundant seasons, by converting the fruit into jam or pulp, or preserving the vegetables in brine, to provide against scarcity in crops for another season; besides, the surplus of each day's sales must be manufactured into jam, pulp, or pickles, thus keeping the market clear, and preventing goods being sold at those ruinously low prices that are obtained at the end of the market, which disheartens the grower and damages the shopkeeper, who has given a fair price at early market. Now, in many cases the salesman has not the capital or the convenience to carry out this system and thus prevent a glut; if he had that would be no benefit to the grower, as the profits would go into his pocket, and he would get a commission of 5 or 7½ per cent. on the raw fruit for selling to his own jam factory, and 25 to 50 per cent. more on the manufactured jam or pulp. My opinion is that it is to the manipulation of this surplus that the growers in an extended fruit cultivation must look for the profit they will reap for their trouble, and I should advise fruit associations or companies, supported by capitalists or growers who can act as their own salesmen, and to whom large jam makers can apply for their supplies of

fruit. This would be a great boon and a great saving to large jam boilers.

I think there is but one way of dealing with the produce with the most advantage to the seller, and to the immediate benefit of the people generally, and that is by a combination of the landowners, farmers, market gardeners, fruit and vegetable growers, agricultural labourers, and all classes interested, to form companies or societies properly and carefully organised and carried on in large centres, to provide for the reception and sale of produce, so that all classes may be interested in the success of such undertakings; so that sellers may depend upon having, without delay, the fair market value of the goods sent for sale; so that they may depend upon a sale of their goods at such prices with certainty, at the same time having an interest in a well paying company, out of the profits of which they would be reimbursed most of the expenses of selling their produce for the year.

To make such a company successful in any large centre is easy. It may be formed amongst capitalists, as companies generally are formed, or it may be the parties specifically interested who may combine to start and support it. The latter, I think, would be the more profitable combination, as it certainly would be the more preferable, and in such a case I think it should be a company co-operative in principle, registered under the Companies Acts, limiting the liability of the shareholders to the amount of their shares, and the capital should be of such an extent as to create confidence in the whole community of senders, whether shareholders or not; and it should admit of taking premises, or building if necessary, and acquiring plant of such an extent and nature as to stamp the company "respectable" and stable, and so as to attract the consumer. The shares issued should be so varied in amount as to enable and induce all classes to become shareholders. Under the present system senders of produce have only the salesmen's returns to depend upon, and they have no means of verifying them. In order to insure a sale of sender's goods at market prices the company might take a number of shops in different parts of the town, to which might be sent fruit, vegetables, poultry, game, or produce of any description, including meat if necessary, and provide a means for disposing of goods which could not be sold at the central depot at fair market prices. The company would also be able to buy fruit and vegetables when the markets were full from other salesmen, thus providing for seasons when particular crops failed, or of which the prices ran high, and so be independent of the markets as a means of supply, without being crippled for want of any particular sort of fruit or vegetable for the season. As an instance of the inconvenience and loss occasioned by being placed in such a position I may mention a circumstance that came to my knowledge in February, 1885, when Broccoli was plentiful—so prolific the yield that it did not pay to send to market. In October of the same year one firm of pickle makers were compelled to pay 2s. 6d. and 3s. per dozen for Cauliflower which they might have bought for 6d. to 9d. per dozen in the early part of the year, and to keep their trade together they bought hundreds of dozens. Another advantage might be given to senders of goods for sale. If a quantity of goods were actually consigned and viewed by the company's agent in any town, on production of the consignment note, an immediate advance might be made to the sender.

It has been pointed out to me that to do all this would require an immense amount of capital, and that it would be next to impossible to work a company so extensive in its operations. To those who have not carefully considered the subject it may so present itself, but the difficulties are few, and none that cannot be met by systematic management. Its machinery would not be nearly so complicated as that of the Civil Service Supply Association, for instance, nor would the capital employed be required in it, or the amount of stock to be held at any one time ever approach in magnitude for any one district to that of the Association referred to. As to the commission business, beyond the initial outlay this department would not absorb capital, as the moment business was commenced the earnings in it would begin to accrue, and, receiving goods on commission only, there would be no outlay excepting for current expenses, whilst there would always be capital at the company's bankers. When goods were received and sold the proceeds would go into the bank, and assuming that all accounts were made up on the day of sale and crossed cheques sent to senders the same night they would not, as a rule, be presented until two days afterwards, and frequently three or four days, by which time more goods would have been received and sold, and the money paid into the bank as before. The company would thus have the benefit of senders' capital, at the same time settling their accounts with the greatest celerity. The greatest importance attaches to prompt settlements in this business. As generally conducted by private salesmen the returns are made and the cash remitted weekly,

but there is no reason why it should not be sent at once, as it is often of importance to the sender that he should have his money, and, as the trade is for cash, there can be no reasonable excuse for not doing so. The cost of keeping horses, carts, and men would be more than saved by the company being their own carters from the railway stations, as the railway companies charge 2s. per ton for "cartage," and in the course of a year in an extensive business this charge amounts to a large sum.

IMPROVING ORCHARDS BY GRAFTING.

By Mr. J. MILLER

WHERE old fruit trees that are healthy and full of vigour are worthless for the market in a monetary sense, no time should be lost in grafting upon them new heads of an improved variety.

If the system of stock-grafting was better understood, especially out of the fruit-growing districts, worthless sorts would seldom be seen in the market, their place being taken by more profitable fruit. But to expect this is to be done by the tenant, upon a yearly tenancy, is out of the question. To meet the difficulty to a certain extent, industrious tenants should be supplied with trees from the home nursery, or could be supplied by the trade at small cost, the tenant being under an agreement to protect them. Stock-grafting is easily done, but the system requires to be known. As done in the fruit districts by local grafters, each workman bears a degree of merit as to his success. When once known, none need be afraid to cut off the third part of a worthless tree any time during the winter months, cutting it ship-shape in order that the grafter has little to do when the season comes but to square the ends of the branches and insert his grafts. The season for grafting large trees is rather an unsettled question. I may state that we had great success last year at Ruxley Lodge in grafting old trees, and the strong shoots which I exhibit speak well for the system. The heads were cut off the trees in the month of February, and grafts were secured about the same time and laid by the heels in a shady place to prevent any premature growth. The grafts for this require to be clean and free from American blight and canker, from two to three years' growth, and in size about the thickness of one's second finger. The specimens of shoots which I produce were simply short grafts a year ago last May, the whole of the grafting being done in the last fortnight of the month. The work has only been done about sixteen months, yet the shoots have had two seasons' growth, and reach nearly 10 feet in length; some of the stronger sorts are even longer. Upon a close examination some of the strongest shoots may be seen to be showing fruit buds, and if we should be favoured with a fruitful season next year I have no doubt, from present appearances, we shall have a fair show of fruit. Stock-grafting does not require to be commenced so soon as small whip or tongue grafting. The general order is—Cherries first, Plums next, finishing up with Pears and Apples.

The tools which are required for the purpose are but few—a pocket knife, a shoemaker's knife, a tenon saw, and a small mallet.

A branch 2 inches in diameter requires two grafts to thoroughly unite the end of the branch; one of 4 inches, three grafts; and so on in proportion. A stock or head of 9 inches requires seven grafts in order to keep the head living until the leading shoots form the new tree, then all weakly and ill-placed shoots can be cut away. There is no particular secret in manipulating the end of the branch to receive the grafts further than shaving away a portion of the rough bark, so that it may better match the thin or inner bark of the scion, which ought to be placed so as to accurately face each other. Daubing or claying up the grafts is no doubt of some importance, especially for small grafting. For trees grafted upon the stock principle the daubing material may be of a coarser nature than for the whip or tongue grafting. Good clay with a proportion of tough hay, well compounded together, and thoroughly worked in and round the grafts to prevent its being washed off by the weather, is all that is required for stock-grafting. I may here state that heading the trees at the proper time and securing and properly keeping the grafts is of quite as much importance as carrying out the work.

* * We did not receive the papers of Messrs. Bath, Smith, and Beach.

DISCUSSION.

Mr. A. Dean, in proposing a vote of thanks to the readers of the papers, condemned the extravagant statements at a recent provincial meeting as misleading, and said that agriculturists should not be induced to plant extensively at once, but rather a few acres now and more later on as experience was gained and demand increased. It was regrettable, he thought, that so much land was occupied with cider Apples when the same space would give a much better return if occu-

pled with good market varieties. Mr. A. H. Pearson, in seconding the vote of thanks, considered one great mistake into which many cultivators fall is rushing the fruit all to one centre. He grew 80 acres of Apples and found a convenient market for them in Nottingham. He thought growers might often find a better market near at home. Mr. J. K. Fowler referred to fruit-preserving, and said that this should now receive more attention than jam-making, as a great field was open in that direction. Mr. Peter Veitch of Exeter remarked that though cider Apples had been condemned, it should be remembered that they mostly grew upon comparatively poor land quite unsuited to the culture of better varieties. Mr. Reed, Oatlands Park Gardens, Weybridge, considered pyramidal trees the most profitable, and advocated a more general adoption of root-pruning. He said the numerous old neglected fruit trees seen throughout the country should be destroyed, cordon, espalier, or pyramids of good varieties being planted instead, which would materially alter the returns, and alter many persons' opinion of the advantages derivable from fruit cultivation. Mr. H. James of Norwood regretted that so much land was unoccupied or uncultivated, which, if let at reasonable rents, could be rendered profitable to landlord and tenant. Mr. D. T. Fish hoped all would carefully consider the weighty remarks of their Chairman, and he also hoped that Mr. Rivers would be able to supplement his list of the best fruits for good land with a selection of the best to grow on poor or second-rate soils. Mr. G. Bunyard said with regard to analysing soils this could be readily done when they were of a uniform character, but when as varied as they were in the neighbourhood of Maidstone, it was a difficult undertaking. Much could be done to renovate old orchards by judicious applications of manure, and by giving more than is usual. Pruning should be done when the trees are in leaf, as it could be more readily seen what should be removed and what retained with benefit to the tree.

The vote of thanks was carried unanimously, and the meeting adjourned until the next day.

ON Saturday, September 8th, Mr. T. F. Rivers took the chair at 2 P.M., when there was again a good attendance of growers. The principal paper was that by Mr. Tallerman on the "Science of Fruit Distribution," which was followed by one on "Fruit as Food," from Mr. Manning.

THE SCIENCE OF FRUIT DISTRIBUTION.

By D. TALLERMAN, ESQ., K.F.J.

OF the various means available to fruit growers for the disposal of their crops, that by which they can be brought within the reach of consumers in a full flavoured, fresh, and bright condition is the one which will leave the most profitable results to the producers, and lead to the most successful permanent development of the industry in which they are engaged. Fruit may be preserved, pulped, evaporated, refrigerated, or manipulated in any other manner that will enable it to be converted into a merchantable commodity possessing a distinctive cash value, but there yet remains the undeniable fact that it is in its fresh ripe condition, while clothed with its undisguisable natural bloom, endowed with its fragrant aroma and luscious flavour, that fruits have their highest and best values; therefore the most important subject that can occupy the minds of fruit growers is, how they can best place their produce within reach of consumers in that inviting condition, in order to acquire the full benefits that accrue from it. This subject naturally involves a consideration of the means of rapid and effective distribution which are absolutely essential to secure successful results.

The science of fruit distribution is necessarily a commercial study, and comprises the principles that growers should practise to place their produce within reach of consumers.

1st, When and where they may be required.

2nd, In the best possible condition.

3rd, At the least possible cost.

The means by which these measures, simple as they appear, can best be successfully attained, involves attention to matters of detail, the necessity of which will be readily acknowledged by all engaged in fruit growing and marketing; but to ensure a beneficial result from the consideration of the subjects which we are assembled to discuss, it is necessary to treat the various branches of the trade from specific and not general points, inasmuch as although the general condition of the subject may be speedily summarised, that will not bring us any nearer the position we hope to reach. Briefly, then, we are a large community existing in a small space. Fruit consumers abound in all directions, fruit producers are to be found but in few places. The consumers are counted by millions, the producers by hundreds. The consumers require all the fruit that is grown and more; the growers do

not profitably sell while fresh the yield of their orchards, and are driven to seek other outlets in order to secure even a nominal return for their crops. It must be borne in mind that the circumstances and conditions that surround individual growers and consumers vary very largely, and courses of procedure that would bring advantageous results in one direction would be inappreciable in another.

With growers we have a wide range of conditions to deal with, from the owners of the numerous old orchards of large acreage to which little or no attention is given, to the cultivators of small quantities of choice fruits under glass or in the hothouse, which are the subject of incessant care and watchfulness.

With consumers we also have an infinite number of conditions which embodies a still wider range of thought, for from the wealthy members of the upper classes who require, and will have at all times if procurable, for their tables regardless of cost, any fruits that may be rare, choice, and of fine quality, to the buxom matron who buys a couple of pounds of whatever fruit the costermonger may have on his barrow, so that her husband's and family's dinner may be complete with its dumpling or pie. Every variety of condition has to be met with and provided for, therefore it must be evident that the more these existing and varied circumstances are understood, and the nearer they can be met and provided for, the greater must be the benefits that will accrue to fruit producers. It is in the study of the numerous features that present themselves, and the determination of the most advantageous manner in which they can be encountered and dealt with, that comprises the science of fruit distribution. This opportunity does not enable me to enlarge upon the whole of the subjects which are naturally affiliated with the question, therefore I content myself by indicating the directions to which attention may be advantageously given.

With respect to the first point—viz., the disposal of fruits, when and where they may be required. I would point out to growers that with the exception of the county of Kent and the Metropolis, the centres of fruit production and fruit consumption are not contiguous to each other. By an inspection of the diagram of the kingdom, showing the population and the fruit area of each county, it will be seen that the bulk of our fruit supply is produced in a very few districts, while a large portion of the country which is densely populated is devoid of any fruit produce of their own locality but rely upon other districts, and that the people gladly purchase any quantity of fruit that may be brought to them in good order and condition. That this position is undeniable may be gathered from the results that have attended the efforts of a few private parties who have relinquished the old practice of sending to the markets of Covent Garden, the Borough, and Spitalfields, and despatch their fruits instead to Manchester, Bradford, Leeds, Glasgow, and other largely populated northern towns, where they have made a profitable outlet for a large quantity of fruit that otherwise would have helped to glut the London markets. There are an enormous number of small towns in the mining and manufacturing districts that would welcome a supply of fresh fruit which they do not now obtain. In order to directly meet the requirements of these towns it is desirable that the fruit growers of each district combine with each other and organise themselves into local societies in order that they may be in a proper position to ascertain what fruits they have to sell, when they will be ready for gathering, and then ascertain the requirements of particular districts and what they are likely to buy, so as to enable them to take steps to supply them. It is not possible to attain this position by individual action, for no single grower could supply from his own crops the particular requirements of the traders of a town, but these requirements if once ascertained, which they may be in a general sense, could be furnished from the crops of several growers.

Where local organisations are thus formed they could readily communicate with the central organisation that has been formed to place itself in communication with the traders of all districts, in order to simplify the distribution of food products, and they by ascertaining the probable fruit requirements of a district, and having a knowledge of the crops of fruit that were available in many localities, could arrange to dispose of and deliver them direct from the orchards. The defect that fruit-growers suffer from arises from the fact that while their transactions are naturally of an individual character, and must remain so, they have had no recognised central representative organisation who could collect information from varied districts as to their possible fruit requirements, and disseminate the knowledge among those who had the fruit to dispose of, and also arrange many other subjects of interest and importance, such as packages, railway rates, transmission, &c., all matters small in themselves and readily adjustable, but each of which forms an indispensable connecting link in a commercial chain, without which a transaction cannot be carried through. Hitherto fruit growers

have left everything with their salesmen, whose interest it is to collect and retain all the information, and to obstruct any course by which the consignment of the fruit to themselves would be interfered with. They therefore have a vested interest in obstructing any movement that would have a tendency to impart to growers any information that would advise them when and where fruit was required, which is the keystone to the system of direct distribution.

The second prominent feature incidental to scientific distribution is the delivery to consumers just what they want in the best possible condition. The interests of sellers will be considerably advanced by full attention being given to this subject, which presents many features requiring careful consideration and forethought, that without in any way adding to the costs of cultivation and delivery may materially aid to increase the amounts receivable for the fruits.

Be it remembered that no fruits grow exactly all alike, the same as bricks are made, but every tree or bush will contain some fruits of a more or less choice character. Wherever these can be selected they will if packed by themselves realise a much larger proportionate price without interfering with the price of the whole crop. There are different classes of buyers in all perishable food products, and more especially in fruits, and there are different members in each trade who supply the requirements of buyers. Anyone going into an average sized orchard when the fruit is ripe and ready for gathering will, upon examination, discover choice specimens fit for an exhibition or the window of the highest class fruiterers at the West End of London. Other fruits may be seen that, by themselves, would furnish a reasonable supply of more than a general character. Further, there will be seen the remainder of the growth suitable for the costermonger's barrow or the jam pot. If they remain while the fruit is gathered they will see it all packed together in such a way that no regard is paid to the choice specimens of fruit that may be there, but they are so dealt with that they will all find their way to one destination, which, as likely as not, may be the costermonger's barrow. This is the mistake that growers make, and where they unknowingly suffer material loss.

The disposal of green fruits is necessarily a matter of commercial experience, and to attain best results all fruits should be properly assorted and classed as to character, condition, and description—this in America is called "grading." Fruits thus dealt with and placed in packages of a uniform size enjoy a marked advantage in their disposal, as buyers at a distance may order them by description, while at present they can only be purchased by personal attendance and sight. The South of Ireland and the North of Scotland furnish examples of the great value attaching to the proper classification of perishable produce, for it is to the independent branding of butter at Cork and herrings at Wick and the other Scotch fishing ports, that have brought the trades of those districts to their present high stage of development, for it is owing to the facility which the storekeeper in the colonial bush can send to his merchant in London for what he requires in Cork butter, either in firsts, seconds, thirds, or fourths, knowing exactly what he will get, and can learn the current market price on the day of purchase. Equally the same the grocer of an inland town in eastern Europe can send to his Hamburg agent for so many barrels of Scotch herrings, and can order "Crown Pulls," "Spents," or "Matties," and his exact requirements are supplied owing to the wise precautions those in the Scotch herring trade have adopted, by which not only are the character of the contents of their barrels known by description all over the world, but the single fisherman with his few barrels of herrings enjoys an equal position with the largest factor of the district, and can readily obtain the market price of the day for his small supply when they have once been examined and branded by the appointed officials. This should show fruit growers the advisability of their combining for the purpose of establishing a definite basis upon which their produce should be classed and uniformly packed, by which the contents of a package would be known to wholesale and retail dealers without a personal inspection. For this purpose fruits should be properly sorted and classed as to character and condition into—

1st, "Choice," for special high-class trade; "Prime," for first-class trade; and "Ordinary," for general trade.

2nd, Assorted as to description into firsts, seconds, and thirds sizes.

3rd, Choice and Prime fruits should be packed into clean, bright, and carefully made packages, so as to present to the buyer a luscious, attractive, and tempting appearance. Ordinary fruit may be packed for general sale in smaller baskets than at present.

4th, It is important to act on the principle that the smaller the package the wider the area of consumption, and the better the contents will keep in good order and condition.

5th, Also that selection as to size and colour with regular packing

are the best means for ensuring speedy sales in extended districts at good prices.

6th, Growers should remember and act on the fact that a barely perceptible taint or speck that is carelessly dealt with by the packer at the farm will in a short time become an odious blemish, and by the time the fruit reaches the market, not only becomes spoiled itself, but damages other fruit and spoils its value.

7th, A good crop requires marketing with commercial experience and judgment. A combination of growers to amalgamate their crops in order that large selections of particular descriptions may be made available for disposal in special directions, and in districts where required, will lead to larger prices being received.

8th, Specially choice goods, suitably packed for display in retailers' shop windows, will at all times command extreme high prices.

9th, Inferior specimens of fruits packed with prime specimens, reduce the value of the prime.

10th, Goods packed, branded, and numbered that their contents and condition may be known without a personal inspection, will be sent for by purchasers in remote parts, whose convenience or ability does not allow them to attend a market personally.

The simplicity, ease, and readiness by which these apparently complicated measures may be speedily carried into active existence will be promptly seen by a glance at a package that has been devised for the purpose, which lends itself in every way to the proposed condition of things, for inexpensive in production it is effective in character, as by its means fruits may be classed, packed, and safely transmitted to any part of the kingdom in large or small quantities, where they will arrive in better condition, and remain so longer than if packed in bulk as at present, also may be disposed of to the individual consumer without any handling and consequent deterioration. The inexpensive character of the package is its valuable feature, and that is 6d. per dozen for the boxes and 5d. for the crate to hold twenty boxes. Their lightness renders the cost of transport less than in the heavy baskets, which have to be sent backwards and forwards, while fruits selected and packed in this manner would be deliverable in the best possible condition and of the highest value. Thus the second material feature in the science of distribution would be complied with.

The third feature to which attention may be directed is the transport of fruit at the least possible cost. I do not propose to occupy time by referring to that great evil, the excessive railway rates, which the producers and consumers of the country have so long suffered from. The short-sighted policy of the railway authorities is about to be brought under consideration, and our purpose will be best served by attention being directed to the particular points that fruit growers should endeavour to secure for themselves in the forthcoming revision of the charges and conditions of our railway system. In this matter, so far as fruit is concerned, facilities for its effective collection, safe transport, and speedy delivery, are of a much greater consideration than the actual charge made for the services rendered, but this should certainly be a figure within reason; but the principal object that the agricultural classes generally, as a body of producers, should seek to obtain, is a ready means for reaching consumers in all districts through the existing retail traders. For this purpose they should seek for the establishment of a "farm produce train," a service to be carried through on the lines of the "parliamentary train" and the "van train," which was in existence for a number of years, and only recently abandoned. By the parliamentary train the passenger rates for one train daily was fixed by 11s. The van train was for parcels, and the rates were made by the railway companies themselves, being one-half the ordinary parcels rates. With a minimum of 6d. at the present time, a parcel traffic is in existence on all railways by passenger trains, and this is governed by radius of distance; up to thirty miles being $\frac{1}{4}$ d. per lb.; up to fifty miles $\frac{1}{2}$ d. per lb.; up to 100 miles, $\frac{3}{4}$ d. per lb., with a minimum rate of 6d. for a parcel. A moderate extension of this parcel system to wider radiuses on the basis of the van train charge—that is, one-half the current parcel rates, would prove advantageous to farmers, and bring the railway a large and remunerative traffic. This should be sought for, and would probably be conceded by the railway company without difficulty.

The outlet for fruits will be found in two directions which have a widely different character, and necessitate different treatment—the supply to London and the few very large towns in the north, and the supply to the small towns and villages throughout the kingdom. With the first we have the large concentration of fruiterers, greengrocers, and costermongers, who have hitherto furnished the means for reaching the public. With the second they have to a great extent done without fruit, as it could not be supplied in a fresh condition. Whether the

fruits are intended for London or the country districts, railway companies should be compelled to provide effective refrigerator trucks for their conveyance, in order that its fresh condition may be fully maintained. Growers know the condition that fruits leave them, but they are not aware of the serious deterioration that takes place in transit before reaching their destination, and the consequent enormous depreciation that takes place in values. A few hours makes a great difference in the appearance and flavour of fruits, and there can be no possible justification for the unnecessary loss thus made to the detriment of the grower, when the fruits could be readily and inexpensively retained in a fine and fresh condition.

In America the fruit farmers of California and Florida, the extreme western and southern States, send their fruits two and three thousand miles across the vast continent to the markets of New York, Baltimore, Boston, Chicago, &c., where they arrive in fine condition after several days' travel, and invariably bring good results to the grower, while in this country a fruit grower cannot send his produce a few miles with any certainty of its reaching its destination in a presentable condition, and if he wishes to send any distance other than where an ordinary fruit train runs, there is almost a certainty that it will be useless when it arrives at its destination. This deterioration and its consequent loss is more than a personal loss of the particular sender, it is a diminution of the food supply of the people, and in that light it is a national loss, needlessly incurred by reason of the negligence and want of care on part of those who have acquired the right to transport the internal food supplies of the country, a loss which is readily preventible by the use of proper trucks, which the railway companies should be compelled to provide themselves or allow others to provide for them. The companies should also be called upon to accept a truck rate for agricultural produce irrespective of contents. This would enable fruit and other farmers to load trucks in proximity to their farms or on railway sidings with their own labour, and while saving charges send their produce direct to the market. The provision of a regular and effective daily service for the conveyance of parcels of food produce in refrigerator cars, at a reasonable advance on the ordinary goods rates, would materially facilitate the communication between producers and consumers, and lead to marked advantages to fruit growers. To simplify matters, the rates by this produce train might be fixed within given areas. Thus all within a radius of one hundred miles one rate, and each additional hundred miles an additional rate. This would bring most of the agricultural districts within reach of populous towns, and thus furnish them with an outlet for their produce. That this system would be advantageous to fruit growers may be readily seen, for grocers, dealers, or even consumers in any small town might order any number of the packages of fruit from one upwards, which, packed on the orchard and transmitted by the refrigerator cars, would reach their destination direct, at a small cost and in good condition. The essence of the fruit trade is a multiplication of individual transactions small in extent but numerous in character. It is in the simplification of the distribution of these that growers will be in a position to place their produce within reach of consumers at the least possible cost, and thus acquire a further insight into the science of fruit distribution.

To summarise, in conclusion, I submit—

1st, That the simplest and most profitable way to sell fruits is in their natural condition properly classed and packed.

2nd, That an ample demand can be ensured for an unlimited quantity from numerous districts in all parts of the kingdom.

3rd, That these can be best approached and dealt with by local combinations of growers either direct or through a central agency.

4th, That whatever prices are determined upon should be publicly known and fixed to give retailers a profit.

5th, That the railway companies should be moved to furnish a daily farmers produce parcel and bulk train service for the carriage of food products in refrigerator trucks between the agricultural and industrial districts at reasonable package and truck rates.

With the supply of these facilities a demand would be created for their utilisation, and thus bring about an improved condition of all things in which the interests of our agricultural and industrial classes are entwined.

* * Mr. Manning's paper arrived too late for insertion.

DISCUSSION.

Mr. J. Cheal of Crawley in returning to the leading subject of the Conference, observed that the question had been asked as to whether fruit could be profitably grown on at least some of the secondary soils of the country. In answering this he might say that it could, as they had

experience of this in Sussex, but more care was required, more preparation for planting, and more attention subsequently. A list of Apples that would be suitable for good soils would be unfitted for those of a poor character; for instance, they found Lord Suffield could not be grown with profit on poor soils in Sussex, and Lord Grosvenor was found to be preferable. He agreed with Mr. Rivers that careless planting was answerable for many failures in fruit culture. The ground should be well cultivated to a uniform depth, in order that water and air should have a free passage, not merely digging holes to stick the trees in. He had recently seen some poor land in Sussex owned by an amateur, who had planted a number of fruit trees in narrow holes that were little better than pits or graves for the trees. Trees also should not be planted deeply, but preferably on the surface, raising the soil over the roots, and stiff soils should be carefully stirred. Stocks also required consideration. He considered fruit growers ought at least to be able to supply their home markets. By the aid of Conferences and Associations like that at the Crystal Palace much might be done to show how land can be profitably cultivated, but it must not be expected that fruit trees would succeed without attention; the results depend entirely upon the thought, care, and labour expended.

Mr. Alderman Chaffin of Bath said plenty of cheap land could now be obtained, and there was no reason why it could not be made to pay a good per-centage on the outlay. The chief difficulties in the way of profitable fruit culture were the cost of transit, the heavy tithes, and the expense of distribution by means of "middlemen." An extended knowledge of what varieties of fruits to grow in particular localities was important; also a knowledge of the soils and their qualities. He thought growers should combine among themselves, selecting agents and dividing the profits after deducting the expense of selling. A vote of thanks to the readers of the papers was proposed by Mr. Bunyard and seconded by Mr. Pearson, both of whom made some interesting remarks upon the subject, and Mr. Hammond commented upon the importance of more careful packing, the selection of fruits in different qualities, and greater honesty on the part of vendors who wished to secure good returns.

Mr. T. W. Beach, Brentford, read a short paper upon drying and preserving fruits, illustrated by samples of Pears, Plums, Cherries, &c. in various stages.

Mr. J. Cheal proposed a resolution to the effect that it was desirable an association of fruit growers should be formed for the promotion of profitable fruit cultivation, and to improve the methods of distribution, the Executive Committee of the Conference being requested to prepare a report on the subject, to be submitted to the next meeting at the Crystal Palace on October 11th this year. He said he had much pleasure in submitting this to the meeting, as he believed such Conferences as they had had on that and the previous day would do valuable service. Mr. Fowler seconded the proposition, which was carried *nem. con.*

A vote of thanks to the Chairman was then proposed by Mr. Tallerman, seconded by Mr. Laing, and carried by acclamation. Mr. Rivers, in replying, said they had every reason to be satisfied with their first Conference, and the thanks of all concerned were due to the Crystal Palace Company and officials for the assistance rendered to the promoters. He also wished to say that the credit of having originated this successful Conference rested with Mr. G. Gordon and Mr. L. Castle. The meeting was then adjourned to the first day of the Hardy Fruit Show at the Crystal Palace on October 11th next.

CABBAGES AGAIN.

WHEN I saw the notification of a reply having been received to my gentle critique on page 163 I naturally looked forward with anxiety to the Journal containing the "short and sweet effusion." On perusing this it is more than ever clear to me that my combative opponent who "lets them have it right and left" has something to learn on Cabbage growing, or he would not suspect a "mystery" in Ellam's Early Cabbage being superior to Early York in spring, but inferior to it in the autumn. I am bound to express my astonishment at being asked to explain such a simple matter, still as information is confessedly needed it must be given. If "A Kitchen Gardener" had grown both the varieties from spring-sown seed, as I have, he would have solved the mystery, for in all probability Ellam's would have merited his strong condemnation for splitting while the Early York that he said would "never be a favourite again" would have secured his laudation for remaining intact, sound, and tender. He says he is "no autumn Cabbage eater." I have not the slightest objection to that. I grow Cabbages to please myself and others who like them, and we have not found any better at the time when they are wanted, and provided, than Early York; but to sow it in autumn for bolting in spring, and then condemn the variety, is in my view putting the blame in the wrong place.

I observe "A Kitchen Gardener" shows his natural boldness even in

quotation, for if he can find I said "there is no variety in existence equal to Early York for sowing in spring," as he alleges, I venture to say no one else can find that sentence in the article from which he takes it, nor any other conveying the same meaning. I prefer to be quoted accurately, though I always feel that no one can misquote another without weakening his own position. In this case, however, it was no doubt accidental—a slip of the pen, but a mistake all the same.

There are other causes that contribute to the bolting of Cabbage plants in spring besides early sowing. If I mistake not the distributors of Ellam's Early, Messrs Veitch & Sons, advise on the seed packets that it be sown on the 10th or 12th of July (I forget which), and they would not do that if, as my opponent says, it would "never answer." In my experience the vendors are perfectly right, and I know, and could have shown "A Kitchen Gardener," a bed of 3000 plants in Yorkshire ready for cutting in March from seed sown on the first-named date, and not three dozen of them bolted, though it might not be the same every season and in every district.

Spring-sown Cabbages are ready too soon this season. They are the most useful in the autumn, and if I only made one sowing it would be the last week in May, and for the purpose in view I have not grown one variety to excel the Early York, but should be sorry to say there is not one variety in existence equal to it. "A Kitchen Gardener" can scarcely have grown the true Dwarf Early York from spring-sown seed, or he would not be so widely at variance with the examiners of the Chiswick trials, who, according to the report on page 186, placed it among the best six out of forty spring-sown varieties, and earlier in the season it was recorded that Ellam's was certificated because of its value for spring use. Thus the mysterious conjunction over which your correspondent stumbled is solved by authority, and both varieties rank among the best in their respective seasons for use.—A YORKSHIRE CABBAGE GROWER.

SPORTS.

SOME of us are, perhaps, less likely to see these than others. My Roses are a great pleasure to myself, but I also try to make them a source of happiness to others; hence almost daily my few hundred plants are clipped, every Rose worth anything being cut and sent to friends who have none. So, if the sport in my case were at all a damaged flower, I should cut it without looking to see what it was. But in the way of sports I have had a curious experience. Some five years ago Mr. Prince, in sending me some Roses, added two plants of Merveille de Lyon. This, I think I am right in supposing to be a sport from Baronne de Rothschild, but anyway derived from her ladyship. I did with these two plants, when they came, what I generally do—I cut all the shoots that I should not require for the following year, leaving all the others full length. These pieces that I cut out I inserted in the ground under a small frame, and ten or more struck. The following autumn these were planted out, and being anxious that they should do well, they were not put in my ordinary bed, but in a place by themselves, so there is no possibility of mixing. The following winter was awful. Last winter was ditto repeated, only worse, and several died. They did not do very well last year, but one of the plants brought pinkish flowers, more like the mother, but as they were poor in condition I thought this might be accident. This year they have done fairly, and the plant in question has become unmistakably a Baronne de Rothschild; but one of the other plants has turned to Mabel Morrison, another sport from the Baroness. On this plant I had a very pretty Rose, several of the white petals having touches of light pink, some of the splashes taking half the petal. I have inserted the buds of the stem on which this bloom grew. Just as an additional link in this history, at our local Rose Show the Rev. W. Gardiner of Box showed a Baronne de Rothschild bloom, which, retaining its pale blush colour, had two or three of its petals splashed with much darker pink. The plant of my own that seems to have become a Mabel Morrison has had blooms with the thinness of petal of that Rose, and quite unlike the number that we see in Merveille de Lyon.—Y. B. A. Z.

ROSES IN WINTER.

THERE is a very general impression that Niphetos and such like varieties are exhausted much sooner when planted out than when they are confined in pots. This is a matter of importance. The idea may be new to some, but it has been brought to my notice on several occasions and by different persons interested in this particular subject. If it can be proved that the plants become exhausted in less time when planted out than when they are grown in pots, then planting them out would appear to be a great mistake.

Only a few years ago the Manetti was held up as the stock for Roses, and they were manufactured upon it wholesale. I have again and again in these pages pointed out that those who praised this stock were advocates of Roses upon their own roots, and that the Manetti was useless as a stock except to manufacture Roses upon quickly. I

firmly believe that the impression stated above has had its origin from this very source. In spite of the fact that fine flowers can be cut from maidens on this stock, it is nevertheless useless for working very strong growers upon. Weak and moderate growers may live upon it and do well, but strong growers are liable to collapse if they do not root freely from the union of the Rose and stock by deep planting. Strong growers will use up this stock in a very short time; Maréchal Niel, Gloire de Dijon, and others will kill it in about twelve months. Even the moderate growing Teas, if they are grown strongly and do not root freely from the union, will not last for any great length of time. When the union is buried they do not always root freely from it unless they have been covered with soil almost directly they leave the propagating pit.

I can readily understand that plants grown in pots would last longer on this stock than if planted out. The treatment they must receive to keep them in good health would promote a more moderate growth, and thus they would last longer than those grown luxuriantly in a prepared border. I know perfectly well that instances can be adduced that even strong growers have lived for many years upon this stock, but they would prove the exception, not the rule. I am not writing in a condemnatory vein of the Manetti because I have favourites to adduce. One stock is as good as another to me as long as it answers the purpose satisfactorily for which it is used. I have watched with peculiar interest the Manetti and its behaviour as a stock since I first had to make cuttings of it in the autumn of 1871, and believe it to be useless for several Roses, and practically worthless unless the Rose can be induced to root freely and become independent of it. I would not plant out Niphetos worked upon it if I knew it, but should not hesitate to plant Safrano, Isabella Sprunt, or any that I know would emit roots from the union as quickly and freely as those two kinds. I will return to the subject.—WM. BARDNEY.

MRS. PINCE'S BLACK MUSCAT GRAPE.

WHEN well grown this has no equal as a late Grape, although it will not keep so long in condition as Lady Downe's. So this excellent variety should also be grown so as to prolong the season. Imperfect setting and want of colour are the evils which have been raised against Mrs. Pince, but the former is easily overcome by drawing a camel-hair brush over the bunches when in flower, and the latter may be averted by not cropping too heavily, and by allowing the light to play directly on the bunches. Shade by an abundance of foliage has been recommended to obviate the evil of defective colour, but this is a great mistake with the Grape in question. We have a Vine planted at the west end of a lateinery, and noticed last season where the light struck the bunches directly there the colour was the densest. I intended to write concerning this Grape last season, so as to confirm what was stated by a writer respecting Mrs. Pince as grown at Longford Castle. We have some very fine bunches with large berries colouring beautifully. Coarse varieties are now becoming too largely grown, but in due time these will find their level. Gardeners who have tables to keep supplied with superior fruit know the praise which is bestowed on well finished bunches of this excellent Grape.—A. YOUNG.

ARTIFICIAL MANURES.

THE satisfaction with which Mr. M. Coombe regards the enlightened state that he has suddenly discovered has dawned upon my mind is gratifying to me, because many of the truths elucidated are entirely opposed to the views he formerly advanced, but which have of late been reduced to the point where they can be put into practice.

I have no intention of reopening this discussion, but as my opponent seems somewhat puzzled to define the difference between the "judicious combination" I find in his recent remarks, and the "properly proportioned ones" he formerly so strongly advocated, I will try to put the matter in words incapable of being misconstrued. The judicious combination referred to is brought into action by using the knowledge we possess in preparing food for plants, no matter whether that knowledge is obtained by the aid of science, practical experience, or close observation, so long as it supplies the food found to produce the best results. The properly proportioned combination theory is giving to plants that food which according to science should be perfect; but unfortunately no method has yet been devised by which this theory can be reduced to economical and successful practice, hence the gradual change of Mr. Coombe's remarks. I have in no instance opposed the application of science to gardening or farming, as I believe the greatest amount of success will be attained by those who have a good general knowledge of plant life, and whose perceptive faculties and daily experience enables them to test their science step by step, discarding those chemical niceties that are found unnecessary, turning to account the natural resources within their reach, and thereby triumphing over the difficulties which beset their path. Knowledge is in itself a tremendous power, but it is a notorious fact that those who possess the greatest amount of knowledge are by no means the most successful in life. Something else is needed—viz., the ability to turn to practical use every atom of knowledge gained. This is the unerring passport to success in nations and individuals alike.

Before taking leave of this subject I gladly express my thanks to Mr. Coombe for having, by means of his candid criticisms, brought forward a subject of so much importance. In the future I shall deem it within my special province to keep watch upon his literary productions,

and should I find his enthusiasm lead him to advance scientific theories in an impractical form I may again try conclusions with him. If, while I am pursuing my scientific studies in peace in the hope of producing a perfect plant food, Mr. Coombe will diligently set about the task of acquiring the knowledge necessary to analyse soils and manures, he will be able to inform me when I have successfully accomplished my task from an economic and also a scientific point of view. Our united efforts should then reduce to a simple, efficient, and practical system the use of artificial manures.

I join with my late opponent in the expression of hearty thanks to the Editor for the freedom allowed in this debate, and I trust that those readers who have been wearied by its length will be satisfied with its termination.—H. DUNKIN.

[We again congratulate our correspondents, both on the ability they have displayed, and the admirable tone maintained in the discussion that at present terminates, and which cannot fail to have been both interesting and instructive to many readers.]

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 11TH.

THE Exhibition hall was well furnished with plants and flowers, several being new and rare, and good collections of fruit were staged, the orchard house specimens, grown in pots by Rev. W. Wilks, being remarkable for their size, and attracted much attention.

FRUIT COMMITTEE.—Present: R. D. Blackmore, Esq., in the chair, and A. H. Pearson, J. Cheal, P. Crowley, J. Bennett, J. Willard, W. Warren, W. Marshall, G. T. Miles, and J. Wright.

Violette de Bordeaux, a medium-sized purplish Fig, sent from the Society's gardens at Chiswick, was approved by the Committee as of good quality, but a certificate was not awarded. Tomato Ascoug's Champion, sent by Messrs. Hurst & Son, Houndsditch, was recommended to be tried at Chiswick. It is a rather small fruit, and may possibly not prove to be very dissimilar from the Chiswick Red. Devonshire Quarrenden and Irish Peach Apples, the former fine and well coloured, the latter of excellent quality, were sent by Mr. W. Roupell, Roupell Lodge, S.W., and having regard to the fact that they were grown within five miles of Charing Cross, a cultural commendation was recorded. Mr. Roupell also sent a seedling Tomato, very much like Perfection. Pride of Lincolnshire Pea, very large and fine pods, sent by Mr. J. Marriott, Boston, was referred to be grown at Chiswick for trial with other varieties. Mr. Williams, Blenheim Palace Gardens, sent a good looking and well netted Melon, but not of high flavour, but the variety appears to be worth trying during a brighter season. Mr. A. Dean sent a dish of the Early Harvest Apple, a good early variety, but the fruits were not quite ripe.

Rev. W. Wilks sent a seedling Apple, the Vicar, said to be a free cropper and good grower in poor soil. The specimens were very good, and thought to resemble the Domino. They were gathered from the seedling tree, and more will perhaps be heard of this variety, which is of promising usefulness. Several other dishes of fruit were sent by Mr. Wilks, and a cultural commendation awarded. They were grown in pots in an orchard house. Cox's Orange Pippin Apples were 3½ inches in diameter, eleven grown on a tree in a 12-inch pot, and Hornmead Pearmain 4 inches wide, 3½ inches deep, fourteen being borne on a tree in a 10-inch pot. The above were splendid examples of culture, as were several Pears, and a cultural commendation was unanimously awarded. Mr. D. Tallerman sent fruit of Strawberries, Gooseberries, Rhubarb, and Potatoes dried by the Blackman Ventilator Company, Fore Street, London, and the Committee desired that examples be prepared, cooked, and reported upon by the Committee in charge of the cool storage trials of fruit.

An excellent representative collection of fruit, also cordon Plums bearing fine crops in pots, were exhibited by Messrs. James Veitch and Sons, and a vote of thanks was awarded.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., in the chair, and Messrs. W. Wilks, J. Walker, W. Goldring, W. Bates, J. W. Lowe, R. Dean, T. Baines, C. Pilcher, J. Dominy, H. M. Pollett, J. O'Brien, E. Hill, Shirley Hibberd, W. Holmes, J. Fraser, and G. Nicholson. Messrs. Kelway & Son, Langport, Somerset, contributed a large collection of Gladioli spikes wonderfully bright and fine, representing a large number of varieties, including several new ones (silver Banksian medal). Mr. W. Gordou, Twickenham, sent a handsome group of Liliun lancifolium and L. auratum varieties associated with Japanese Maples and Adiantums (bronze Banksian medal). From the Royal Horticultural Society's Chiswick Gardens came a collection of Asters, very bright and varied in colours; large heads of Hydrangea paniculata grandiflora also came from the same gardens. Mr. G. S. P. Harris, Orpington, Kent, showed a stand of Dahlias, for which a vote of thanks was awarded. Mr. Cook, Kingston Hill, sent two plants of Lælia elegans, one having a spike of ten fine flowers of good colour. Mr. T. Butcher, Croydon, sent plants of Carnation Blushing Bride, very soft delicate pink, free and of good habit.

F. G. Tautz, Esq., Hammersmith (gardener, Mr. Cowley), was awarded a cultural commendation for a well grown plant of Oncidium macranthum var. Williamsi, having a very long raceme of flowers. W. Soper, Esq., 307, Clapham Road, sent a cream and crimson coloured Colcus (vote of thanks). Mr. B. S. Williams, Upper Holloway, sent several Orchids, comprising a fine Miltonia candida, Mesospinidium vulcanicum superbum, and Lælia monophylla. Mr. R. Allum, Tam-

worth, sent a seedling *Adiantum* with small pinnules, and it was described as "the result of spores gathered from *A. Paccoti* and *cuneatum*" and presumably sown together (vote of thanks).

G. F. Wilson, Esq., Weybridge, sent several spikes of Lilies, including *L. auratum* *platypetalum*, *rubro-vittatum*, and *tigrinum* *flore-pleno* from out of doors, showing the bad effects of the recent weather in damaging flowers. Mr. A. Harding, The Gardens, Orton Hall, Peterborough, showed fruits of *Torreya myristica* and a fine cone of *Abies magnifica*. Mr. H. B. May, Edmonton, contributed an extensive group of well coloured Crotons, arranged with Ferns and *Isolepis gracilis*. Several baskets of Bouvardias, Carnations, and Mignonette were also shown (silver Banksian medal). T. W. Girdlestone, Esq., Sunningdale, Berks, showed a box of single Dahlias, one of which was certificated. Mr. R. Dean, Ealing, exhibited several varieties of Phlox, Pentstemon, and Dianthus. Mr. T. S. Ware, Tottenham, had his usual beautiful group of hardy flowers, chiefly Phloxes, Lilies, and Poppies (silver Banksian medal). Mr. F. Ross, Pendell Court Gardens, Bletchingley, sent flowering branches of the white *Arauja* or *Physianthus albens*, which has been described and figured in this Journal.

CERTIFICATED PLANTS.

Lilium nepalense (H. Low & Co.).—A most distinct *Lilium* introduced a few months since, the first time it has flowered in this country. Plant of slender growth, 3 to 4 feet high; leaves lanceolate, 3 to 4 inches long, each stem terminating in a single flower, but in its native country it is said to have as many as sixteen each. The flowers are about 4 inches in diameter, drooping with recurving petals, deep gloomy maroon tipped with yellow.

Eremurus Olgae (T. S. Ware).—A majestic plant, with a tall spike several feet in length of closely set bluish-tinted flowers darker in the bud.

Romneya Coulteri (T. S. Ware).—Leaves and stems glaucous, the leaves irregularly cut; flowers pure white, 5 inches in diameter, with a dense tuft of yellow stamens in the centre. Very suggestive of a Poppy.

Tritonia aurea, *crimson spotted* (J. O'Brien).—One flower of this was shown, the petals orange yellow with a crimson blotch in the centre of each.

Gladiolus Castro (Kelway).—Flowers very large, bright salmon pink, white centre.

Chrysanthemum Mrs. H. Hawkins (Hawkins & Bennett).—A bright golden sport from G. Wermig; blooms large with broad florets.

Disa graminifolia (F. G. Tautz, Esq.).—One of the small blue-flowered *Dias* after the style of *D. lacera*, and produced in a slender scape without leaves like that species. A botanical certificate was awarded.

Oncidium ornithorhynchum album (B. S. Williams).—A graceful variety with a spreading panicle of white flowers, having a yellow crest at the base of lip.

Carnation Madame Carle (B. H. May).—An excellent variety, with neat pure white fragrant flowers.

Dahlia Mikado (T. W. Girdlestone, Esq.).—A single variety with large blooms and broad florets, bright crimson yellow at the base and the tip.

Dianthus splendens (R. Dean).—A single variety, described as a cross between *Dianthus Heddegi* and *D. barbatus*; brilliant crimson, slightly darker in the centre, and fringed at the margin.

Laelia monophylla (B. S. Williams).—A small slender plant with narrow leaves and one flower of a bright orange colour. A botanical certificate was awarded.

A MEETING of the Floral Committee was held at Chiswick on September 6th. Present Mr. H. Herbst in the chair; Messrs. Nicholson, Baines, Pollett, Holmes, Dean, Dominy, and Wildsmith.

The collections of Asters on trial in the gardens were examined, when the following awards were made:—

Received from Messrs. Vilmoren, Andrieux, & Co., Half-dwarf Multiflora, eight vars., strain commended; Imbricated, twelve vars., strain commended, indigo blue, receiving three marks; Globe Paony-flowered, rose, three marks; Imbricated Pompon, thirteen vars., strain commended; Dwarf Chrysanthemum-flowered, eleven varieties, strain commended, flesh coloured, scarlet copper, and lilac white edge, three marks each; Crown Asters, lilac, three marks.

Received from Herr Ernst Benary:—Dwarf Victoria, seven vars., strain commended, lilac rose, indigo blue, and light carmine, three marks each; Dwarf Cocardeau or Crown, four vars., strain commended, rose, crimson, and violet, three marks each; Dwarf Paony Perfection, rose, glowing dark scarlet, light blue and white, three marks each; Lilliput, eight vars., strain commended as being valuable for late flowering purposes; Paony-flowered Globe, twelve vars., strain commended, white, brilliant lilac, peach blossom, rose tipped with white, carmine and white, purple and white, and crimson, three marks each; Victoria Needle, eight vars., strain commended, fiery scarlet, three marks; Large-flowered Rose, twelve vars., strain commended, dark scarlet, three marks; Victoria, eighteen vars., strain commended, white, white turning to azure blue, peach blossom, carmine rose, reddish lilac, light blue and white, and white turning to rose, three marks each; Imbricated Pompon, nineteen vars., strain commended; Truffaut's Paony-flowered Perfection, strain commended, rose and white, carmine, light blue, black blue, and dark scarlet and white, three marks each; Tall Chrys-

anthemum-flowered, eleven vars., strain commended, slate blue, three marks; Hedgehog or Poreupine, twelve vars., strain commended.

Received from the Speciality and Novelty Seed Company: Dwarf Victoria, scarlet, three marks.

GRAPES SCALDING.

I CAN endorse what Mr. Bardney stated concerning the scalding of Grapes, and I can assure Mr. Young that it is no fancy of Mr. Bardney's when stating that "the Black Hamburg will scald as badly as Lady Downe's if the necessary precautions are not taken." I have seen Black Hamburg very badly scalded, and in one instance under my own charge, "the necessary precautions" had been neglected by the man responsible for the airing of the vineries. The scalding of Black Hamburgs, it must be admitted, is not so general as with late Grapes, the former being more generally grown when there is a greater difference between the inside and outside temperature, which necessitates a greater amount of fire heat; consequently the air of the house would be correspondingly drier. When Black Hamburgs are grown with little assistance from fire heat, I consider they are just as liable to scald as any other Grape, if the "necessary precautions" are neglected. It is of very great importance that the ventilation of vineries during the stoning process should have thorough attention, and young men who have charge of them should make themselves thoroughly acquainted with that which is the cause of the mischief, and work accordingly.

I cannot agree with Mr. Young in having "no fixed temperature." The practice may do with an experienced hand, but for the guidance of young men a stated temperature should be attached to the thermometer, and adhered to as near as possible; there is no excuse then on the part of those in charge. An experienced hand may walk into a house and know the temperature without referring to the thermometer, but this is not the case with the inexperienced.—W. SIMPSON, *Knowsley*.

SUMMER-FLOWERING VARIETIES.

JUDGING from the absence of these flowers from many of the reports recently published, it may be surmised they are not so generally cultivated as is desirable. They have been, however, very effective in borders this year. Mr. W. Piercy, who devotes much attention to this class of Chrysanthemums, sent the flowers that are engraved. The dark flowers represent Blushing Bride (which the engraver has made to blush rather too deeply), the two lower light ones L'Ami Couderchet, and the upper ones Fiberta or Flora, we forget which, and the point is immaterial, as both were sent to the artist and both are good. Writing on the varieties, Mr. Piercy says, "Blushing Bride is the best in its line, and is of a very bright transparent blush colour, growing 2 feet high. It was imported from France by Mr. N. Davis. It is remarkable in that it blooms twice in one season, and is the only one that will do so except Nanum, the Sistou of the French, which it does not resemble in any other way, except that they are both dwarf stiff plants, doing well without sticks. It is not nearly so well known as it should be. L'Ami Couderchet came to me from Lyons a season or two back, and is the best of its type in cultivation. It is a pretty little pale primrose flower, somewhat resembling Petite Marie, but, unlike that, is robust, easy to grow and to keep bushy, and 18 to 20 inches high, blooming in August. Fiberta is a beautiful lemon yellow Pompon, blooming profusely from July to October; and Flora is in some respects still the best yellow Pompon, being very bright and free. Early Chrysanthemums are advancing yearly, but it is too soon to record the progress of the season."

NATIONAL CHRYSANTHEMUM SOCIETY.

SEPTEMBER 12TH AND 13TH.

THE first of this Society's exhibitions for the present year was held in the Royal Aquarium, Westminster, on Wednesday and Thursday, and proved very satisfactory, Dahlias especially being well shown. Over 600 feet run of staging was occupied with exhibits, the competition being keen in all the leading classes.

Mr. T. S. Ware, Tottenham, had the best collection of cut Chrysanthemums, representing thirty-two varieties, all fresh, bright, and good; Mr. R. Owen was second with about thirty varieties, and Mr. J. P. Kendall, Roehampton, third. The variety Madame Desgranges was capitally shown. Mr. J. Blackburn, gardener to J. Scott, Esq., jun., Elmstead Grange, Chislehurst, was first with wonderfully pure blooms; Mr. J. Hudd, gardener to F. W. Prior, Esq., Gordon House, Blackheath, was second, and Mr. H. Elliott, gardener to Mrs. Lawrence Harrison, Leyden House, Mortlake, third. Mr. Witty of Highgate had a good collection of Pommoms, winning first prize. Mr. Elliott had twelve grand blooms of G. Wermig in the any variety class. Mr. A. D. Clarke, gardener to W. B. Brand, Esq., Finchley, was second, and Mr. H. Neary third. For six bunches of Madame Desgranges Messrs. Scott, Hudd, and Doughty were the prizetakers. Mr. J. R. Witty, Highgate, had the

best group of Chrysanthemum plants well arranged, and Mr. Neary the best twelve specimens.

Dahlias were extremely fine and very numerous. With forty-eight blooms Mr. C. Turner, Slough, was first with grand blooms of the leading varieties. Messrs. Keynes, Williams & Co., Salisbury, were second, and Mr. J. Walker, Thame, third. Mr. C. Turner was also first for

good, Mr. H. Glasseock, Bishops Stortford, taking the chief position. Pompon Dahlias were extensively and well shown from Messrs. Cheal and Son, Keynes, Williams & Co., Mr. C. Turner, and others, Cactus Dahlias and single varieties adding to the attractions.

The miscellaneous non-competing exhibits comprised a handsome group of Tuberous Begonias and fine-foliage plants from Messrs. J.

FIG. 26.—SUMMER CHRYSANTHEMUMS.

thirty-six blooms, followed by Keynes, Williams & Co. and Messrs. Saltmarsh. With twenty-four Dahlias Mr. C. Turner was again the most successful exhibitor, followed by Messrs. Saltmarsh and Keynes, Williams & Co. The premier prize for a collection of Gladioli spikes was awarded to Messrs. J. Burrell & Co., Cambridge, the Rev. H. H. D'Ombrian being third. The exhibits in the smaller classes were also

Laing & Son, Forest Hill. Messrs. H. Cannell & Sons, Swanley, contributed a large collection of Show, Fancy, Cactus, Pompon, and single Dahlias, with Tuberous Begonias and brilliantly coloured Cannas.

A meeting of the Floral Committee was also held in the afternoon, several Chrysanthemums and other flowers being shown for certificates.

EVENTS OF THE WEEK.—To-day (September 13th), Exhibition of Chrysanthemums, Dahlias, &c., at the Royal Aquarium, Westminster (second day). Glasgow and West of Scotland Horticultural Society's Autumn Exhibition (second day). Sales of Bulbs at Messrs. Stevens' Rooms next Monday and Wednesday, and at Messrs. Protheroe and Morris's Rooms next Monday and Thursday.

— A CORRESPONDENT writes on **PRESERVING MOUNTAIN ASH BERRIES**:—"Pull when ripe, place them between layers of hay, and they will keep plump for a long time. Without any further care we had some that kept plump and attractive for a year, and were in good preservation when thrown away."

— IN reference to the judging at the recent Salisbury Show, Mr. H. W. Ward, Longford Castle Gardens, writes:—"In justice to the local gardeners who took part in making the awards at the above excellent Show, will you kindly allow me to say that the exhibiting Judge referred to in the *Journal of Horticulture* for August 30th, page 202, does not reside within the postal district of Salisbury."

— **THE DEVONSHIRE POMOLOGICAL SOCIETY.**—The fourth annual Exhibition of Apples and Pears is announced to be held at Exeter on October 25th and 26th, when prizes will be awarded in the fifty classes provided in the schedule. The principal object of the Society is to attract attention to the recognised best sorts of Apples and Pears, and thus conduce to an improvement in the special culture of these fruits in the county of Devon and the West of England. The Right Hon. Sir T. D. Acland, Bart., is the President, and Mr. Isaac Pengelly, Guildhall, Exeter, the Hon. Secretary of the Society.

— **BRIEF NOTES.**—Short communications on subjects of interest are acceptable for this column, and Mr. Arthur Young obliges with the following five "Notes":—

— **WHINHAM'S INDUSTRY GOOSEBERRY.**—This is a most valuable addition to our hardy fruits, as it is very prolific and handsome in shape. It is valuable for picking green, or for remaining to become ripe. An acre or two would be a good investment.

— **CARNATIONS MRS. REYNOLDS HOLE AND JAMES FITZPATRICK.**—The former Carnation has proved itself a valuable acquisition, and is a favourite with all who see it. The latter (James Fitzpatrick), also sent out by Messrs. Dicksons of Chester, is another decided acquisition. It is of the same colour as the Tree Carnation Miss Jolliffe, but with a fringed edge. It is a very free bloomer, and, like Mrs. Reynolds Hole, is what is termed a border Carnation.

— **LEYCESTERIA FORMOSA.**—This handsome shrub is now in full beauty. A short time since the bushes were covered with drooping panicles of flowers, and these are now succeeded by bunches of claret-coloured fruit, almost like bunches of Grapes. Some authorities term it a half-hardy evergreen, but this is a mistake, for here upon the Worcestershire hills it is quite hardy without any protection whatever. The soil is a cold limestone clay, and during the winter the weather is very severe.

— **ECKFORD'S SWEET PEAS.**—Last season we purchased a small packet each of Eckford's new varieties of Sweet Peas. These were mixed at the time of sowing, and at the present the row is a sight to behold. It is a mass of handsome flowers of various colours. A great advance has been made during the past few years in Sweet Peas. At first the change was hardly noticeable, but now it is very apparent. In a year or two hence we may expect to find still greater improvement.

— **MELON, THE BLENHEIM ORANGE.**—Are the new Melons which are continually cropping up better flavoured than the varieties of a few years ago? I think not. I suspect the old varieties are not kept true, and so dwindle away from the original stock. I believe we have the true stock of Blenheim Orange, and I do not think there could be "handsomer, better flavoured, better fruiter, or better constituted

Melon. There is no difficulty in keeping the main foliage green and healthy to the last, and this means good flavoured fruit, whatever the advocates of the "drying off" system may think. My neighbour, Mr. J. Austin of Witley Court, also relies upon the "Blenheim" exclusively, and rare crops of fine fruit he has.

— **GARDENING IN INDIA.**—We have pleasure in inserting the following announcement from Mr. W. Goldring:—"You may perhaps consider the fact worth recording in the *Journal* that I have been commissioned by His Highness the Maharaja Gaekwar of Baroda to go out to India to design and lay out some magnificent gardens around his palaces at Makarpura and Laxmiviloso at Baroda, and other public parks and gardens in His Highness's dominions. I have engaged to spend three winter months (December, January, and February) for the next three years in India, so that I shall be able to continue my home practice, which of course is at a standstill during those months. The Gaekwar, whom I have recently interviewed in Switzerland, is greatly interested in gardening, and he is desirous of advancing horticulture in Baroda in harmony with European ideas."

— **POTATO COLE'S FAVOURITE.**—Mr. W. Iggulden writes:—"On lifting the crop of this variety I was agreeably surprised to find a capital lot of tubers with only a very few diseased ones among them. The haulm died down somewhat prematurely, and I fully expected to find the bulk of the crops badly diseased. Instead of this we have a capital lot of medium sized tubers as 'handsome as paint,' not one deep eye to be seen on them, while the quality is first rate. It is one of the best to use in succession to the Ashleafs or other early varieties, and as far as we are concerned would be included in a collection for extensive culture and limited to six varieties. Our stock came from Messrs. J. Veitch & Sons, and I have not noticed quotations for it in any other catalogue."

— **A PROLIFIC PLUM.**—In the Plum-growing districts of Worcestershire and neighbouring counties the variety known as Pershore is most largely planted, this being found one of the most reliable for marketing purposes. It is wonderfully prolific, quite young trees bearing good crops. The fruit is rather small, of a greenish yellow colour, and is principally recommended for cooking and making into jam. Gisborne's, a variety somewhat resembling the Pershore, proves to be even more profitable than the latter, and is now being largely planted in preference to it. I have recently seen rows nearly a mile long of Gisborne's, which, though only planted about four years, were carrying remarkably heavy crops of saleable fruit, and intending planters ought to make a note of it.—I.

— **GROS MAROC GRAPE.**—Are there not two forms of this handsome, though by no means high-class, Grape in cultivation? One form produces short thick bunches with large round berries, but which do not colour so readily as in the case of another form that has much longer bunches and oval shaped berries. These two forms may sometimes be seen in one house, both being on a similar stock, the grafts, however, being obtained from different sources. This noble-looking Grape colours perfectly in a cool house, but the quality is improved by a little fire heat. Extra fine bunches have been exhibited this season in various parts of the country, but none that I saw were perfectly finished, and it is doubtful if large bunches have so much weight with the judges as those who exhibit them imagine.—W.

— **THE WAKEFIELD PAXTON SOCIETY.**—At the last weekly meeting of the members of the above Society Mr. A. Goldthorpe presided, and Mr. J. G. Brown occupied the vice-chair. Considering the unfavourable state of the weather there was a good attendance. The subject for discussion was "Carnations and Picotees," and there was a splendid show of specimens grown by members of the Society, the exhibitors including Mr. Gill, Eastmoor; Mr. J. Maddock, Lofthouse; and Inspector Corden. Mr. Maddock's blooms were much admired for their exceptional richness of colour. A number of blooms were also shown by Mr. G. Armitage of the Morley Paxton Society, who attended and gave a lecture on the cultivation of the flower, pointing out the best methods of propagation and the treatment by which the most perfect blooms could be obtained. Mr. Armitage advocated the old fashioned method of layering in preference to cuttings. A good discussion followed the lecture, and at the close a vote of thanks was accorded to Mr. Armitage and also the exhibitors.

— THE subject selected by Mr. W. T. Thiselton-Dyer, President of the Biological Section of the British Association at Bath, was the STUDY OF BOTANY AS PURSUED IN THIS COUNTRY. As the head of one of the great national establishments of the country for the cultivation of systematic botany, Mr. Thiselton-Dyer devoted a considerable portion of his time to that branch of the science. He thinks that the present outlook of systematic botany is somewhat discouraging; but congratulates us that no country affords such admirable facilities for work as are now to be found in London—with the Herbarium of Linnæus at the Linnean Society, the rich collections of the older botanists in the British Museum, and the constantly increasing material at Kew. On the other hand he complains that in physiological literature the importance of precise nomenclature is overlooked, and urges that the central problem of systematic botany is to perfect a natural classification. In his closing sentences he reminded his hearers that, whether they took the problems of geographical distribution, the most obscure points in the theory of organic evolution, or the innermost secrets of vital phenomena, not to consider plants is still, in the words of Darwin, a gigantic oversight.

— IT will probably be conceded by most gardeners that the want of sun has been a greater obstacle to contend with this season than an excess of rain. The weather reviewer of the *Daily News* reports as follows on THE SUNLESS SUMMER:—"The publication of the last weekly report of the Meteorological Office enables us to review the weather of the season with regard to the prevalence of bright sunshine. Taking the past thirteen weeks as a whole, it would appear that the total amount of this most essential element has been very deficient in all parts of the country with the exception of Ireland and the north of Scotland. In the former of these regions, the aggregate duration of sunshine has not been more than from 2 to 4 per cent. less than the average of the previous eight years; while in the north of Scotland it has actually been 11 per cent. in excess of the normal. Over England, however, matters have been very different, the deficiency varying from 20 per cent. in the north-western district, including North Wales, to 28 per cent. in the north-eastern and midland counties, and to as much as 34 per cent. over the southern and eastern counties. Over all the more central eastern and southern parts of England, in fact, the sun has not shone on an average for more than from four to four and a half hours per day, instead of a possible fourteen or fifteen hours. In Scotland the daily average has been about five hours, and in the Channel Islands about six. A comparison with the brilliant weather of last year gives some very striking results. Over England generally the quantity of sunshine registered during the season which has just elapsed has been little more than half the amount recorded a year ago. In the eastern counties the average daily amount this year was 4.3 hours, against 8.5 hours last year, and in the southern district 4.3 hours, against 8.4. Owing to the marked absence of sunshine the deficiency of heat noticed during the past summer has been relatively much greater during the daytime than at night. In London the mean of the midday readings for the entire period has been more than 4° below the average, while the deficit in the night values has not amounted to as much as 1°. Notwithstanding the general coolness of the season, the absolute minimum temperature, or, in other words, the lowest reading observed in London on the coldest night, has been higher than any similar value recorded during any summer since the year 1873. During the past three months the thermometer has not descended below 49°. Last year the summer, although so fine and warm, gave us a minimum temperature of 39°, while in the summer of 1880 the sheltered thermometer on one occasion fell as low as 35°."

PEACHES ON OPEN WALLS.

NOTWITHSTANDING an adverse season like the present Peaches have again proved that they may be grown successfully on open walls, in the south or west of England at the least. In the gardens here we have a wall 100 yards in length covered with healthy trees from end to end, and all, with one exception, are bearing full crops of fruit. Of course, we had the usual impediments to combat, but with perseverance all insect pests were overcome, thanks to liberal applications of tobacco water. I believe many crops of Peaches have been lost this season through insufficient protection during the flowering season. At that time we had two or three very cold days with an east wind blowing. During that time the trees were covered night and day, and that saved the crop. To be successful with Peaches in the open air the trees must have the same attention as if growing under glass, both in respect to branches and roots. Partial root-lifting or pruning must be practised every other

season or so, and the border kept firm, mulched, and watered when necessary. The width of the border is about 6 feet, and this is not dug nor cropped in the least. Alexander and Hale's Early are good early Peaches, but it is not advisable to plant too many of this class, as the quality is not equal to the good standard varieties. The following are the varieties grown on the open walls in these gardens. Peaches—Hale's Early, Alexandra Noblesse, Barrington, Dr. Hogg, Grosse Mignonne, Noblesse, Prince of Wales, Stirling Castle, Royal George, Sca Eagle, Walburton Admirable. Nectarines—Violette Hâtive, Lord Napier, and Pitmaston Orange.—A. YOUNG, *Abberley Hall Gardens, Stourport.*

CRYSTAL PALACE.

FRUIT SHOW.—SEPTEMBER 7TH AND 8TH.

POSSIBLY larger shows may have been seen at the Palace, but not many better, except of Apples and Pears, which are necessarily smaller this year than usual. The collections were good, Grapes represented by many fine, but a few unripe examples, while Peaches, Nectarines, and Plums were generally creditable to the producers.

COLLECTIONS.—These, as usual, formed an important part of the Exhibition. Three classes were provided for not less than twenty, twelve, and eight dishes. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, gained the premier award in the first-mentioned class, showing well-finished and very fine bunches of Alnwick Seedling, Muscat of Alexandria, Foster's Seedling, and Black Hamburgh Grapes, Bellegarde and Downshire Peaches, Violette Hâtive and Pitmaston Orange Nectarines, two handsome Melons, an even brace of Pines, and a dish each of good Negro Largo Figs, Jargonelle Pears, Mr. Gladstone Apple, Vicomtesse Hericart de Thury Strawberry, Cherries, Currants, Gooseberries, Oranges, and two lots of Plums. Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, was second with good bunches and well coloured berries of Madresfield Court and Gros Maroc Grapes; Muscat of Alexandria and Foster's Seedling were rather smaller; Peaches, Nectarines, Apricots, large and richly coloured; large Pines, Melons, Figs, Plums, Cherries, also Strawberries of the same variety as shown in the first prize collection, but smaller fruit. Mr. A. Evans, gardener to S. Hodgson, Esq., Lythc Hill, Haslemere, was third. Excepting Grapes, Melons, Peaches, Nectarines, and Pears, the specimens were rather small.

In the class of twelve dishes, Mr. A. Miller, gardener to W. H. Long, Esq., M.P., Rood Ashton Park, Trowbridge, won the chief prize with fine even bunches of Muscat of Alexandria and Black Alicante Grapes, Blenheim Orange and Rood Ashton Melons, the latter a handsome looking fruit having a clear yellow skin; a capital Smooth Cayenne Pine, Apricots, Peaches, Nectarines, Figs, Apples, Pears, Cherries and Plums. Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, Warminster, was an excellent second, showing splendid Grapes, large and well coloured; Apricots were small, but the remainder all good. Mr. H. W. Ward was third. In the class for eight dishes, Mr. R. Parker, gardener to J. Corbett, Esq., M.P., Impney Hall, Droitwich, secured the foremost place against six other competitors, staging superb bunches of Muscat of Alexandria and Alicante Grapes, fine examples of Princess of Wales Peach, Humboldt Nectarine, Best of All Melon, Apricots, Figs, and Green Gage Plums. Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, was awarded second with excellent Gros Maroc Grapes, Bananas, and Lord Napier Nectarine. Mr. C. J. Goldsmith, Kelsey Manor Gardens, Beckenham, was a good third. The collection shown by Mr. J. Crawford, Coddington Hall, Newark-on-Trent, contained some good dishes, and was commended by the Judges.

Grapes.—These were shown in large numbers, as many as 400 bunches being staged throughout the Exhibition, collections included. The average good quality was surprising considering the recent bad weather for "finishing" them off. With few exceptions there are no really bad Grapes, but many possessing points of great excellence. Taken altogether they made a splendid feature. The competition in nearly all the classes was keen with the exception of that for Madresfield Court; this brought only three competitors and was certainly the worst class in the Show.

For a collection of ten varieties, two bunches of each, there were only two competitors—Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, Wilts, and Mr. H. W. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, the former being placed first by the superior weight of his bunches and the excellence of some varieties. They comprised Black Hamburgh, fair bunches and berries, but short of colour; Alnwick Seedling, shapely bunches, uneven in berry, good colour, but slightly rubbed; Alicante, good bunches, berries rather uneven, and for this variety only fair in colour; Gros Maroc, small bunches; Madresfield Court, good bunches and berries, but showing the effects of the season in the colour; Gros Guillaume, compact bunches with good berries and colour fair; and Lady Downe's, medium sized bunches of good colour amongst the black varieties; the whites being as follow: Muscat of Alexandria, beautifully shaped bunches, very fine berries, almost perfect in colour; Trebbiano, good bunches, small berries of good colour; and Foster's Seedling, compact bunches of good quality. The second prize collection contained smaller examples, but the quality was very good, the best being Madresfield Court, long tapering bunches with good berries fairly well coloured; Alicante, short chubby bunches, good berries and colour; Black Hamburgh, neat bunches, good colour; Lady Downe's, bunches of good form and colour; Gros Maroc, bunches and colour good; Muscat of Alexandria, small bunches and berries, but

colour good; and Buckland Sweetwater, short stocky bunches, fair berries of good finish.

For a collection of five varieties, two bunches of each, only two competed, the best collection coming from Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, who staged Alicante, large in berry and of fair colour; Gros Maroc, having very large berries, which only required a little more colour to make them perfect; Foster's Seedling, small compact bunch, finely coloured; Duke of Buccleuch, good berries of moderate colour; and Muscat of Alexandria, good bunches, fair berries, and colour. Second Mr. T. Osman, gardener to L. J. Baker, Esq., Ottershaw Park, Chertsey, with good produce.

Black Hamburg, three bunches, brought eight competitors, the best fruit coming from Mr. J. Taverner, gardener to Sir A. K. Macdonald, Bart., Woolmer Lodge, Liphook, who had medium sized bunches with berries of good colour. Second Mr. Jas. Chalk, gardener to G. Read, Esq., Wilton Road, Salisbury, larger bunches, of good form, berries rather small and slightly rubbed. Messrs. Rivers & Son, Sawbridge-worth, were third with clusters rather uneven in berry, but well coloured. For three bunches of Muscat of Alexandria six competed. Mr. W. Taylor, gardener to Jas. Chaffin, Esq., Bath, was easily first with immensely large bunches of good form and colour, with the exception of one—the largest—which was badly spotted at the point of most of the berries, which detracted much from its otherwise handsome appearance. Mr. Pratt was second with finely shaped bunches, larger berries rather loose and not well coloured. Mr. C. J. Goldsmith followed with smaller bunches of good colour.

The next class was for three bunches of Gros Maroc, in which nine competed, Mr. M. Gleeson, Clumber, Worksop, being easily first with handsome bunches, large and even in berry, of beautiful finish, in fact perfect specimens of this showy Grape; Mr. W. Taylor was second with much larger bunches, but the berries very short of colour; Mr. W. Allan was third with the largest berries, but not coloured. For Madresfield Court Mr. W. Taylor was first with large shapely bunches, good in berry, and of fair colour; second, Mr. J. H. Goodacre; third, Mr. J. Berry, Tewkesbury Lodge, Forest Hill. The class for three bunches of Alicante produced eight competitors, the best fruit coming from Mr. J. Hollingworth, gardener to J. F. Campbell, Esq., Woodseat, Uttoxeter, with capitally shaped bunches, though not large, with good berries; second, Mr. W. Taylor, larger bunches, but not so good in finish; third, Mr. C. Griffin, gardener to Miss Christy, Coombe Bank, Kingston-on-Thames. For three bunches of any other white variety nine entered the lists, the best coming from Mr. F. Lee, gardener to Mrs. Lyne Stephens, Lynford Hall, Mundford, who showed large bunches of Buckland Sweetwater, the berries rather uneven, colour good but rubbed somewhat; Mr. J. Berry was second with Foster's Seedling, compact bunches, good berries, and of fair colour; Mr. J. Hollingworth was third with Trebbiano. For any other black variety Mr. Goodacre was first among five competitors with three small bunches of Alnwick Seedling, perfect in form and evenness of berry, also finely coloured; Mr. L. Jennings, Forest Lodge, Farnborough, was second with the same variety, smaller bunches, but good in quality; Mr. F. Lee was third with the same variety.

Baskets of black Grapes, not less than 12 lbs.. Mr. J. Bury, gardener, Tewkesbury Lodge, Forest Hill, was placed first with six faultless bunches of Alnwick Seedling of good form, large in berry, and well finished; Mr. W. Taylor, gardener to J. Chaffin, Esq., Bath, closely followed with heavier bunches of the same variety, but not quite so good in colour; Mr. J. Taverner, gardener to Sir A. K. Macdonald, Bart., Woolmer Lodge, Liphook, was third with Black Hamburg. Mr. G. Duncan, gardener to C. T. Lucas, Esq., Warnham Court, Horsham, was to the front in the corresponding class for white Grapes with splendidly finished Muscats, Messrs. W. Lane and W. Pratt following with admirable examples of the same variety. There were seventeen exhibits in these two classes combined.

Peaches and Nectarines.—These were staged in large numbers, and it was surprising to see how well coloured the majority were considering the season. The most successful exhibitor was Mr. Divers, gardener to J. T. Hopwood, Esq., Ketton Hall, Stamford, who took first honours for a collection of six dishes of Peaches and six dishes of Nectarines, distinct, with large and well-coloured fruits of Crimson Galaude, Dymond, Princess of Wales, Barrington, Bellegarde, and Princess of Wales Peaches; Victoria, Albert Victor, Lord Napier, Pine Apple, Rivers' Orange, and Dryden Nectarines. Second, Mr. Goodacre, with fine fruit of Bellegarde and Downshire Peaches; Rivers' Orange, Pitmaston Orange, and Violette Hâtive Nectarines. Third, Messrs. Rivers.

For four dishes of Peaches, distinct varieties, Mr. Divers was again first among six lots, the varieties being the same as in his previous collection. The dishes were even, and the fruit of capital colour. Mr. McIndoe, gardener to Sir J. Pease, Hutton Hall, Guisborough, was second, his fruit not being so even in size, Golden Eagle and Princess of Wales being best. Mr. Jennings, Farnborough, was third. For four dishes of Nectarines Mr. Divers again occupied the premier position with fine highly coloured fruits of Dryden, Spencer, Pine Apple, and Lord Napier. Mr. Goodacre was second, the fruit being smaller. Mr. C. J. Goldsmith was third. For one dish of six Peaches nineteen competed, producing a fine display. Mr. George Goldsmith, gardener to Sir E. G. Loder, Bart., Floore, Weedon, occupied the post of honour with large highly coloured Violette Hâtive. Second, Mr. W. Manning, gardener to G. Taylor, Esq., Margery Hall, Reigate, with Noblesse; Mr. Divers and Mr. Jennings equal third with Prince of Wales and Crawford's Early. Twelve staged in the class for six Nectarines, the best coming from Mr. J. Douglas, gardener to Mrs. Whitbourn, Great Gearies, Essex, a fine

dish of Humboldt. Mr. G. Duncan, gardener to C. T. Lucas, Esq., Warnham Court, Horsham, who showed Pitmaston Orange, very large, was second; and Mr. J. Bury third. Nineteen competed for the prizes offered for best green-flesh Melon. Mr. Goodacre was first with Royal Horticultural Prize. Second, Mr. W. Sullivan, gardener, Fawkham Manor, Dartford, with Sutton's Imperial Green Flesh. Mr. C. Goldsmith, The Gardens, Polesden, Dorking, was third with the same variety. For the best scarlet-fleshed Melon there were seventeen entries. Mr. C. Waite, gardener to the Hon. Col. W. P. Talbot, Glenhurst, Esher, was first with Hybrid Scarlet; Mr. C. Goldsmith second with Bloxholm Hall; Mr. C. J. Goldsmith third.

Apples and Pears.—These on the whole were of fair quality. For twelve dishes of Apples Mr. A. Waterman was first with good specimens of Ecklinville Seedling, Stirling Castle, Peasgood's Nonesuch, Lord Suffield, Stone's Apple, Lady Henniker, Duchess of Oldenburg, Gravenstein, Red Astrachan, Quarrenden, Kerry Pippin, and Worcester Pearmain. Mr. J. Butler was second with grand examples of The Queen, Frogmore Prolific, Grand Duke. Messrs. G. & J. Lane, St. Mary's Cray, were third, Emperor Alexander being one of their best dishes. Mr. J. McIndoe, The Gardens, Hutton Hall, Guisborough, also had some fine fruit, but uneven in size. But this exhibitor took the lead for the same number of dishes of Pears, showing fruit of excellent quality, including richly coloured Clapp's Favourite and Williams' Bon Chrétien, also immense Beurré Diel and Pitmaston Duchess. Mr. J. Butler was second; his best dishes were very fine Windsor, Beurré d'Amanlis, Beurré Goubalt, Louise Bonne, and Clapp's Favourite. Mr. C. J. Goldsmith was third. Mr. A. Waterman was to the fore with three dishes of Apples (ripe); Worcester Pearmain and Red Astrachan were very bright. Mr. F. Miller, gardener to J. T. Friend, Esq., Margate, and Mr. J. Butler were second and third respectively. Mr. Butler had the best three dishes of Pears.

Plums.—The prizes offered for Plums in three classes of four dishes each brought a good number of competitors with very fair fruit. Mr. A. Waterman was first with red Plums, having Pond's Seedling, Prince of Wales, Sultan, and Victoria; Mr. Thomas Lockie, Oakley Court, Windsor, second; and Mr. J. Butler, gardener to A. J. Thomas, Esq., Orchard Lane, Sittingbourne, third. Mr. T. Lockie was first with yellow and green varieties, staging Jefferson's, Washington, Golden Gage, and Guthrie's Late Gage; Mr. E. Chadwick, gardener to E. M. Nelson, Esq., Hanger Hill House, Ealing, was second; and Mr. J. Neighbour, gardener to E. J. Wythes, Esq., Bickley Park, Chislehurst, third; there were fourteen entries. For the four dishes of purple varieties, Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, Frome, secured first honours with even samples; Mr. H. W. Ward, second; and Mr. T. Lockie third. There were only four exhibitors in the class for two dishes of Figs, and these were only of ordinary merit. Mr. C. Ross, gardener to G. B. Eyre, Esq., Welford Park, Newbury, was first with Bourjasotte Grise and White Marseilles, followed by Mr. J. Crawford and Mr. R. Parker.

Tomatoes.—These were but poorly represented, only three collections of six varieties were staged. Mr. C. J. Waite, gardener to Col. Hon. W. P. Talbot, Esher, being first with large and even fruit. Mr. C. J. Goldsmith was a close second; Mr. J. W. Silver, The Norbury and Streatham Nurseries, third, Silver's Golden Queen being the most noticeable in this collection. Messrs. J. Carter & Co. offered prizes for two dishes of Tomatoes of the Blenheim Orange and Sandwich Island varieties. There were only two competitors, and in both the examples were small. Messrs. Sutton & Sons presented special prizes for nine specimens of Reading Perfection. Mr. G. H. Richards, Somerley, Ringwood, was a good first with large and handsome fruit; Mr. C. J. Waite second. Mr. J. W. Reed, gardener to E. Pettit, Esq., Weybridge, and Mr. E. Chadwick were third and fourth. Nine dishes were staged, and all were creditable.

A first class certificate was granted for a Melon shown by Mr. Brutton, Yeovil. It was stated to be the result of a cross with Victory of Bath and Hero of Lockinge, medium size, well netted, green flesh, and of exquisite flavour; it is named Brutton's Perfection. A similar award was made for Thames Ditton Hero, exhibited by Mr. W. Palmer, Thames Ditton House, the variety being apparently of the Victory of Bath type, and richly flavoured.

FLOWERS.—Gladioli, Asters, Hollyhocks, and other flowers were exhibited; also plants of early Chrysanthemums and Cockscombs. We have only space for the chief prizewinners, and must defer the publication of notes on the Gladioli we have received from "D. Deal." Messrs. J. Burrell and Co., Cambridge, were the only exhibitors in the class for thirty-six Gladioli, and were awarded the first prize. In the amateurs' class for eighteen spikes Rev. H. H. D'Ombraïn was in his old position, first; Mr. E. A. Weston, Colne, following. For twelve spikes Messrs. W. J. Jones, Larkall, Bath; W. H. Apthorpe, Cambridge; and S. T. Wright, Ross, were the prizewinners in the order named. Messrs. Webb & Brand, Saffron Walden; and Mr. F. Blandford, West Dulwich, had the prizes for Hollyhocks; Messrs. Saltmarsh, Janes, and Walters those for Asters. Messrs. J. Prewett, Hammersmith; A. Gibson, Halstead Place; and H. James, Norwood, were placed in the order named for indoor flowers. The prizes for Cockscombs fell to Messrs. T. Lockie, Oakley Court; G. Saunders, Charlewood Park; and R. Spink, Horley; all staging well. Messrs. Davis and Jones, W. Piercy, and G. Miles, Brighton, were successful, in the order named, with good groups of Chrysanthemums. Extra prizes were adjudged to Messrs. Paul & Son, Cheshunt, for a fine collection of cut Roses; to Messrs. Cannell & Sons, Swanley, for a splendid assortment of cut flowers; and to Messrs. J. Laing & Co., Forest Hill, for a grand collection of Begonias.

Miscellaneous.—Mr. C. Ross exhibited six large Smooth Cayenne Pines, which were much admired. Messrs. Thomson & Sons, Clouvenford, sent a basket of Duke of Buccleuch Grapes, very large and well finished. Messrs. J. Cheal & Son had three dozen dishes of Apples. Messrs. G. Bunyard & Co., Maidstone, staged a larger collection, upwards of a hundred dishes of Apples, Pears, and Plums. Among the former Beauty of Bath, Bismarck, Grenadier, Lady Sudeley, Colonel Vaughan, Cardinal, and Domino were conspicuous. Some thirty branches of Plums and Damsons were shown by the same firm, the whole forming an interesting exhibit and merited the extra prize awarded by the Judges. A similar honour was accorded Messrs. J. Peed & Sons, Streatham Nurseries, for about sixty dishes of Apples, Grapes, and Plums, behind which were arranged Maidenhair Ferns, herbaceous flowers, and fruiting cordon Apple trees in pots. Mr. Will Taylor, Osborn Nursery, Hampton, had also a few young trees bearing fine fruits. Messrs. J. Laing & Sons, Forest Hill, exhibited young pyramid Apples trees about 3 feet in height, and bearing large fruit. Messrs. T. Rivers & Son, Sawbridgeworth, contributed a highly interesting collection of fruit trees in pots in the best of health, and well fruited. They were tastefully arranged on a half-circular table, and in front were numerous dishes of excellent Peaches, Nectarines, Apples, Pears, Plums, Cherries, and Grapes. This exhibit came in for a large share of admiration.

Messrs. E. & F. Newton were awarded a first-class certificate for their Reform glazing, as also was Mr. Deards for his Victoria dry glazing, both systems being very good.

NATIONAL DAHLIA SHOW.

BEYOND the slight roughness apparent in some of the show and fancy blooms traces of the adverse season were not very conspicuous at the Crystal Palace on the occasion of the National Dahlia Society's Show on the dates above named. In size and colour the flowers were well up to the average, and the excellence of the Pompon varieties, in themselves a charming feature, as well as the singles, compensated for any slight falling off that there may have been observed in the refinement of the larger blooms. Taken on the whole the Show was, in fact, surprisingly good, as for many years Dahlia fanciers have not had to wage so determined a battle with the elements as in the present wet and windy season. The manner in which they have triumphed over their difficulties is of lasting credit to them, and the Dahlia Society may congratulate itself on the excellence of the 1888 Exhibition after such a season. Details of the awards are appended, and the names of the varieties in each first prize stand are given, the names being read from left to right.

NURSERYMEN'S CLASSES.

Show and Fancy Dahlias intermixed.—Class 1, seventy-two blooms, not less than thirty-six varieties or more than two blooms of one variety. This, the most important class in the Show, produced four competitors and an excellent lot of blooms, though, as before noted, some of them were a little rough. The first prize went to Messrs. Keynes, Williams and Co., of Salisbury, whose victory was a highly praiseworthy one, their flowers being singularly fresh and bright. The blooms were perhaps a little lacking in size, but were redeemed by their excellent finish. The varieties shown were as follows:—Back row: Joseph Ashby, Royal Queen, Harry Keith (2), Duchess of Albany (2), Seraph, Colonist (2), sport from Gaiety, Mrs. Langtry, Mr. Spofforth, Rev. J. B. Camm, Thomas Hobbs, General Gordon, Madame Soubeyre, Gloire de Lyon (2), Gaiety self, Hugh Austin, Rebecca, Gloire de Lyon, Mrs. Kendal, Harry Walton, and Mr. Glasscock. Middle row: William Rawlings (2), Clara (2), James Vick, Eclipse, Richard Dean, Mrs. Kendal, Burgundy, Buttercup, Nellie Cramond (2), Colonist, James Service, Julia Wyatt, Shirley Hibberd, Mrs. Gladstone (2), Harry Walton, King of Crimsons, Gaiety, Rosetta, Mrs. Jefferd, Hon. Mrs. P. Wyndham. Front row: James Huntley, Thomas Goodwin, Robina (2), Diadem, Hon. Mrs. P. Wyndham, King of Crimsons, Herbert Turner, Willie Garratt, Mr. J. T. West (2), Richard Dean, Henry Eckford, Geo. Barnes, Lustrous, Hugh Austin, Mrs. Dodds, Frederick Smith, Mr. Head, Mrs. Shirley Hibberd, Prince Bismarck, Frank Pearse, Miss Browning, James Cocker. Mr. Charles Turner, Royal Nurseries, Slough, was a good second, his stand comprising fine blooms of Mrs. Gladstone, Rebecca, Crimson King, Purple Prince, and R. T. Rawlings amongst others, but all were in capital condition. Mr. M. V. Seale, Vine Nurseries, Sevenoaks, was a moderate third, his blooms generally lacking size and finish. Mr. E. F. Such, Maidenhead, was fourth.

Class 2, forty-eight blooms, distinct, three competitors. A magnificent stand from Mr. Charles Turner (perhaps the best individual stand in the Show) received the first prize in this important class. Excellent alike in size, form, colour, and finish, they were something for Dahlia fanciers to inspect with delight, and young exhibitors to learn a lesson by. The following were the varieties shown:—Back row: Mrs. Gladstone, Jas. Vick, Georgina, Harry Keith, Hon. Mrs. Wyndham, Champion Rollo, Mrs. Rawlings, Mrs. Kendal, a seedling, Goldfinder, Purple Prince, Diadem, Henry Walton, T. J. Saltmarsh, Burgundy, and Mrs. John Downie. Middle row: Willie Garratt, Mrs. Foster, Imperial, Prince Bismarck, Thomas Ridley, Royalty, Charles Wyatt, R. T. Rawlings, The Ameer, Crimson King, a seedling, Mrs. Douglas, Robina, James Cocker, Mrs. Jefferd, and Ethel Britton. Front row: J. T. West, Clara, Mrs. Harris, Mrs. Jefferd, Lady Herbert, a seedling, Flag of Truce, Excellent, Mrs. W. Flack, Olivier, Walter, Mrs. S. Hibberd, Primrose Dame, Jos. Green, Charles Lidyrd, and Mr. Harris. Messrs. Keynes, Williams & Co. were second, their best blooms

being Rebecca, Gloire de Lyon, Rev. J. B. Camm, and Richard Dean. Mr. M. V. Seale was a good third.

Class 3, thirty-six blooms, not less than eighteen varieties or more than two blooms of any one variety, seven competitors. Mr. J. Walker, Thame, Oxon, was adjudged the principal award for a fresh bright stand. The varieties were:—Back row: Mrs. Gladstone (2), Thomas Hobbs, Royal Queen, James Cocker, Queen of the Belgians, Harry Keith, Grand Sultan, James Cocker, Hon. Mrs. P. Wyndham, Colonist. Middle row: John Wyatt, Hope, Thos. Hobbs, John H. Keynes, Joseph Ashby, Wm. Rawlings, Flag of Truce, Burgundy, Mrs. Langtry, Lady Louisa Mills, Mrs. Harris, and John Bennett. Front row: Ethel Britton, Rebecca, N. F. Saltmarsh, Earl of Ravensworth (2), Royalty, Mrs. W. Slack, Peacock, Mrs. Jefferd, Flora Wyatt, J. Green, Mrs. Shirley Hibberd. Messrs. Saltmarsh & Son, The Nurseries, Chelmsford, took second place; their flowers were somewhat small, but otherwise good. Mr. W. Boston, Carthorpe, Bedale, was third, and Mr. C. Hoekney, Greenfield House, Stokester, Yorks, fourth.

Class 4, twenty-four blooms, distinct, seven competitors. A good stand from Messrs. Saltmarsh & Son was adjudged the chief award in this class. The varieties shown were as follows:—Back row: Henry Walton, R. T. Rawlings, Willie Garratt, Mrs. Gladstone, Mrs. Glasscock, Constancy, Harry Keith, and Earl of Ravensworth. Middle row: Mrs. Saunders, William Rawlings, Mrs. Langtry, Burgundy, Ethel Britton, John Standish, T. J. Saltmarsh, and John William Lord. Front row: Hugh Austin, Mrs. Harris, Shirley Hibberd, J. T. West, John Henshaw, Criterion, James Cocker, and Lady Gladys Herbert. Mr. G. Humphries, Kington Langley, Chippenham, was second; Mr. J. Walker third; and Messrs. Paul & Son, Cheshunt, fourth.

Class 5, twelve varieties, five competitors. Messrs. Rawlings, Bros., Romford, took the first prize with a very neat lot, the varieties being (back row) Gaiety, Wm. Rawlings, Pelican, and Rev. J. Goodday; (middle row) Prince Bismarck, Mrs. Langtry, Egyptian Prince, and J. T. Saltmarsh; (front row) Sunbeam, John Henshaw, R. T. Rawlings, and Prince of Denmark. Messrs. J. Gilbert & Son were a good second; Messrs. Cheal & Son, third; and Mr. J. R. Tranter, Henley-on-Thames, fourth.

AMATEURS.

Show Varieties.—Class 6, twenty-four blooms, distinct, two competitors. The first prize fell to Mr. Hy. Glasscock, Rye Street, Bishops Stortford. His blooms were of good size, fresh, and well finished, the varieties represented being—Back row: Nellie Cramond, Mrs. Gladstone, Wm. Rawlings, T. J. Saltmarsh, Colonist, Queen of the Belgians, Mr. Glasscock, and J. T. West. Middle row: Ethel Britton, T. S. Ware, Mrs. Harris, Thos. Hobbs, Miss Cannell, Prince Bismarck, R. T. Rawlings, and Burgundy. Front row: Prince of Denmark, Mrs. G. Rawlings, John Henshaw, Mrs. Shirley Hibberd, Walter, Royalty, W. H. Williams, and Mrs. W. Slack. The second prize was awarded to Mr. Wm. Mist. Ightham, Sevenoaks, Kent. His stand was irregular, Mrs. Gladstone, Burgundy, and one or two others being decidedly weak, but on the other hand, W. H. Williams, Harry Keith, and Queen of the Belgians were good.

Class 7, twelve blooms, distinct, nine exhibitors. Mr. J. T. West, gardener to W. Keith, Esq., Cornwall, Brentwood, secured the first prize somewhat easily, the back row flowers being exceptionally fine, and the remainder bright and fresh. The varieties were—Back row: Harry Keith, R. T. Rawlings, Mr. Glasscock, and Mrs. Gladstone. Middle row: Miss Cannell, Prince Bismarck, J. T. Saltmarsh, and Mr. Geo. Harris. Front row: Prince of Denmark, Mrs. Shirley Hibberd, William Rawlings, and J. T. West. The second prize lot of Mr. T. Hobbs, Lower Easton, Bristol, were somewhat flat and rough, but Mrs. Jefferd, Emily Edwards, and Hon. S. Herbert were fairly well shown. Mr. W. H. Apthorpe, Albion Brewery, Cambridge, was a close third, and Mr. G. Arnold, Leighton Buzzard, fourth.

Class 8, six distinct blooms. This was an exceedingly popular class, there being no less than eleven competitors. The premier prize was secured by Mr. H. Steer, Southwood, near Eltham, who showed neat blooms of the following varieties:—Golden Eagle, Ethel Britton, George Dickson, Miss Cannell, Joseph Ashby, and John Nevill Keynes. The second prize went to Mr. W. H. Smith, Wanborough, Shrovenham, Berks, whose blooms were somewhat small, but otherwise good; and the remaining prizes fell to Mr. W. Scaman, gardener to J. Biggs, Esq., Westbury Lodge, Brentwood, and Mr. Ocock, gardener to Mrs. McIntosh, Havering Park, Havering-atte-Bower, Essex.

Fancy Varieties.—Class 9, twelve blooms, distinct, three competitors. Mr. J. T. West was first with an admirable stand, composed of the following varieties, bright and well-finished examples. Back row: Rev. J. B. Camm, W. G. Grace, Duchess of Albany, and Mrs. N. Halls. Middle row: Frank Pearse, Dorothy, Hugh Austin, and John Forbes. Front row: Salamander, James O'Brien, Mrs. Saunders, and Henry Glasscock. The second prize fell to Mr. Glasscock, who also showed excellently, and the third to Mr. Mist.

Class 10, six blooms, distinct, ten competitors. Mr. H. Steer was the most successful, being placed first for a neat stand composed of Peacock, Henry Eckford, Prince Henry, Lottie Eckford, Goldfinch, and Egyptian Prince. Messrs. Hobbs, Heeremans, jun., and S. Cooper, Cheltenham, were respectively first, second, and third.

OPEN CLASSES.

Show and Fancy Varieties Grouped by Colour.—Class 11, six dark blooms, distinct, eight competitors. First Mr. West with Jas. Vick, Rev. J. Goodday, Harry Turner, Prince of Denmark, Shirley Hibberd,

and Lord Chelmsford. Second Mr. M. V. Seale; third Mr. C. Turner, and fourth Mr. T. Hobbs.

Class 12, six light blooms, distinct, eight competitors. First Mr. C. Turner with Mrs. Gladstone, Flag of Truce, Mrs. Harris, Julia Wyatt, Mary Anderson, and Ethel Britton. Second Messrs. Saltmarsh & Son, third Mr. M. V. Seale, and fourth Messrs. Gilbert & Son.

Class 13, six tipped blooms, distinct, seven competitors. First Messrs. Keynes, Williams & Co. with Mrs. Kendal, H. Walton, Peacock, Mrs. Saunders, Fanny Sturt, and Miss Cannell. Second Messrs. Saltmarsh & Son, third Mr. J. Walker, and fourth Mr. J. T. West.

Class 14, six striped blooms, distinct, seven exhibitors. Messrs. Keynes, Williams & Co. were to the fore here, winning well with capital examples of Prince Henry, Jas. O'Brien, Hercules, Rebecca, Hugh Austin, and Rev. J. B. Caum. Second Messrs. H. Clark & Son, Rodley, Leeds, with smaller flowers, Messrs. Humphries and West being second and third.

Decorative and Cactus Varieties.—Class 15, six varieties in bunches of six blooms each, six competitors. The decorative Dahlias were shown in very fine condition, Mr. C. Turner's first prize stand being most attractive. The varieties were—Empress of India, Mrs. Hawkins, Lady Marsham, William Rayner, Juarez, and Henry Patrick, the latter a very fine pure white. Messrs. Keynes, Williams & Co. were very little in the rear, showing amongst others a beautiful canary yellow named Honoria. Messrs. Cheal Bros. and M. V. Seale were the remaining prize winners.

Class 16, four varieties, five competitors. Mr. H. Glascock, showing Mrs. Hawkins, Empress of India, Juarez, and Henry Patrick, was easily first, Messrs. H. Heeremans, jun., R. Spinks, and J. T. West taking the remaining prizes in the order given.

Pompon varieties.—Class 17, twenty-four varieties, distinct. Pompons were very finely shown in this class, the flowers being perfect in form and colour, and not too large. These remarks particularly apply to the first prize blooms of Mr. C. Turner, his varieties being—Back row: Darkness, Juliette, W. Carlisle, Golden Gem, seedling, Favourite, Lady Blanche, and Gem. Middle row: Admiration, White Aster, Thos. Moore, Cupid, Isabel, Rubens, Rosalind, and Khedive. Front row: Mabel, Dandy, Leila, Ernest, Adonis, Don Juan, E. F. Jungker and Gazelle. Messrs. Keynes, Williams & Co. showed finely for second prize, and Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, were a close third.

Class 18, twelve varieties, distinct, eight competitors. Messrs. J. Burrell & Co., Howe House Nurseries, showed admirably here, and scored a ready victory with the following varieties. Back row: Isabel, E. F. Jungker, Mabel, and Rosalie. Middle row: Cupid, Favourite, White Aster, and Gem. Front row: Darkness, Comte von Sternberg, Butterfly, and Fanny Weiner. Mr. G. Humphries was an excellent second; Messrs. Paul & Son a good third, and Mr. John Henshaw, Rothamsted Cottage, Harpenden, fourth. These were all excellent collections.

Class 19, six varieties, distinct (amateurs). Mr. J. T. West was successful from eight opponents in this class, having Mabel, E. F. Jungker, Gem, Isabel, Little Nigger, and Leila. Mr. Glascock followed, the minor prizes going to Mr. W. Harris, Broomfield, near Chelmsford; and Mr. R. Spinks, Victoria Road, Horley.

Single Varieties.—Class 20, twenty-four varieties, distinct. Messrs. J. Cheal & Sons, Lowfield Nurseries, Crawley, were unopposed in this class, and showed, taking the season into consideration, magnificently. Many great growers have failed utterly with single Dahlias this year, but the Crawley growers showed in their usual form. The flowers were not so large as they have been shown previously, but this ought to be considered a point of merit, large single varieties being objectionable. The blooms were splendidly set up, the varieties represented being—Back row: Exeelsior, Amos Perry, Alha Perfecta, Queen of Singles, Mrs. Kennett, Albert Victor, Alfonso, and Brutus. Middle row: Primrose, Mr. Rose, Monte Christo, Mrs. J. Connick, Miss Linniker, Duchess of Westminster, Negress, and Eleanor. Front row: Duchess of Albany, Hugo, Enchantment, Paragon, Sunset, Formosa, Miss Gordon, and Victoria.

Class 21, twelve varieties, distinct, five competitors. This was more popular than the preceding class, and the flowers were again good. Messrs. Paul & Son, Cheshunt, were first, but the blooms were hardly so smooth as they should have been. The varieties were—Back row: Mrs. Kennett, White Queen, Canterbury Tales, and another. Middle row: Miss Gordon, Mrs. H. Whitfield, Harlequin, and Lutea grandiflora. Front row: Mrs. Boorman, The Bruce, Miss Henshaw, and Dulcina. Mr. Seale was a fair second; Messrs. Jas. Gilbert & Sons, St. Margaret's Nurseries, Ipswich, third; and Messrs. Keynes, Williams & Co., fourth.

Class 22, six varieties (amateurs), two competitors. Mr. T. W. Girdlestone, Sunningdale, won with Corney Grain, Maude Millet, Marguerite, Picotee, Daisy, and George Grossmith. These were all seedlings of 1887 and 1888, therefore additionally interesting. Mr. H. Glascock was second.

Seedlings.—Three or more blooms of any new seedling Dahlia. First class certificates of merit awarded to Messrs. Keynes, Williams & Co. for Fancy Dahlia Matthew Campbell; decorative Dahlia, Panthea; and Pompon Dahlias, Little Ethel, Whisper, Fairy Tales, and Eden. Mr. T. S. Ware, Hale Farm, Tottenham, for single Dahlias, R. C. Harvey, Florrie Fisher, and Mrs. Ramshot. Mr. J. T. West, for decorative Dahlia Beauty of Brentwood and Pompon Dahlia Dolly Keith. Mr. T. W. Girdlestone, for single Dahlias Daisy and Mikado. Messrs. H. Cannell & Sons, nurserymen, Swanley, for decorative Dahlia Yellow Juarez. Messrs. J. Cheal & Son, for single Dahlias Victoria and

Duchess of Albany. Mr. H. Glascock, for single Dahlia Gertrude. Mr. T. Glascock, Bishop's Stortford, for Aster Comet. Descriptive notes must be deferred.

Attractive stands, not for competition, were arranged by Messrs. T. S. Ware of Tottenham, and H. Cannell & Sons, Swanley.

URSINIA PULCHRA.

THIS plant, under the old and well-known name of *Sphenogyne speciosa*, was introduced about 1837, and is first described by Knowles and Westcott in the second volume of the "Floral Magazine," a very useful old book rarely seen nowadays. Under the same name it was figured in "Paxton's Mag.," 1839, page 77, and this is the name under which it is cultivated in gardens at the present time. The accompanying sketch

FIG. 27.—URSINIA PULCHRA.

(fig. 27) will give an idea of the value of this hardy annual for border decoration, as in spite of the unusually wet summer and early autumn we do not remember to have seen such an abundance of flowers as has been produced by the *Sphenogyne*. The seeds are sown in the open air along with the other annuals in early April; all that is required afterwards is simply thinning the seedlings to 6 or 9 inches apart, which is quite near enough, as they have a branching habit, each forming a well-shaped bush literally covered with its bright yellow flowers, the effect of which is greatly enhanced by the dark purple brown spot at the base of the rays and the rich dark disc. Its native country is so far unknown, Paxton states, that it was asserted to have been introduced from South America, and by some from South Africa. The latter guess is probably nearest the mark. It is not mentioned in Harvey and Sonder's "Flora Capensis," and may possibly be a native of the unexplored parts of

Namaqualand or the Ceres district. The variety sulphurea is not so beautiful as the type, the flowers being pale sulphur. *U. anthemoides* is a near ally of the above, differing in having a deep purple colour on the underside of the rays, smaller flowers, and more finely cut foliage. This is a very old plant, having been cultivated in 1795, and figured in the "Bot. Mag.," t. 544, under the name of *Arctotis anthemoides*.—D.

MESSRS. ALEXANDER DICKSON AND SONS, NEW-TOWNARDS AND BELFAST.

NEW HYBRID PEDIGREE ROSES.

I HAVE just returned here from a few weeks' run through Ireland, north and south, and Scotland, including Glasgow, Edinburgh, and the Lake district, commonly called "The Trossachs." Perhaps I should here say that any of your readers who go as far as Edinburgh with gardening tastes should not miss the chance of seeing the Duke of Buccleuch's palace gardens at Dalkeith, half an hour's run from Scotland's beautiful capital. However, I hope to have an opportunity of referring occasionally, as time permits, to notes taken *en route*, so with your permission I commence with Messrs. Dickson's Newtownards nurseries. These nurseries are assuming a world-wide reputation as the home of Hybrid Pedigree Roses. Rather curious that these hybrids seem to do admirably in the United States, and already Messrs. Dickson have large orders from Brother Jonathan, but have not so far been as lucky as Mr. Bennett, the only other Hybrid Pedigree Rose raiser in the empire, who secured £1800 from Mr. Evans, of Philadelphia, for Her Majesty.

I propose specially to note those new Roses, but before coming to them I would like to transcribe a few casual notes made in my walk round with the energetic head of the firm, who now leaves the nursery business proper and Rose hybridisation to his son, who bears his name, and Mr. George Dickson, while he interests himself in high class farming and the breeding of a pure strain of Shorthorns on an adjoining estate of his.

The residence, booking, stores, and despatch offices are at the west end of the town, and although there are four nurseries, some distance asunder, stocked in the customary manner with Conifers, ornamental shrubs, fruit trees, Roses, deciduous trees, &c., I shall merely ask space for notes of that in which the glass structures are situated. These structures number about a dozen, ranging from 50 to 150 feet in length, and provided with all modern improvements in heating, ventilating, watering, &c. Some of these are very ingenious as well as economical. There is a large range of pits, at times heated by stable manure or other fermenting material, but with a series of piping to maintain the requisite temperature in case of need. Most people know how slow the work is of removing the sashes to empty and fill the hotbed stuff, and how handicapped the man with the fork is down in the pit.

Here the sashes can be removed from scores of pits or frames in five minutes, and not only that but the supporting framework which fits into grooves, one man emptying or filling with ease and comfort, can thus do the work of at least five. So on in every department, the object to be attained and the best method of securing it seems to be constantly studied. The heating arrangements seem almost perfect. Two large saddle boilers, much praised for their good points some years ago, had to be discarded for a large one of Witherspoon's "Red Rose" patents, which gives greater satisfaction, and consumes less than half the former fuel.

Messrs. Dickson grow enormous quantities for cut flower purposes to meet the demand at their large seed and general warehouse, Royal Avenue, Belfast, under the immediate supervision of Messrs. Watson and Hugh Dickson. They have developed in a surprising degree also the trade—the demand and supply—for ornamental and flowering window and small conservatory plants. Let me give a few illustrations that may be instructive. Narcissi, Hyacinths, Tulips, Anemones, and all flowering bulbs that keep and "travel" well come in usefully in season. I am glad to say they found an enterprising gentleman farmer, Mr. Mossop, in the Queen's Co., to grow several acres of the former for them very satisfactorily, to meet not only the Irish but American trade. For the whole twelve months of the year their demand for cut Roses, Tea, Bourbon, or Hybrid Perpetual never flags. This seems more or less common to all manufacturing towns. So of Carnations, Pinks, and Picotees. *Gloire de Nancy* is the favourite white Carnation, but it too splits the calyx. Fisher's *W. P. Milner* comes papery and poor here. Would you or any reader name a white Carnation as vigorous as *Gloire de Nancy* that does not split the calyx? Another showy outdoor favourite useful for cutting are *Gladioli*, including the hybrids of *Gandavensis* and *Lemoine's*. I have seen them here as fine as the best from salubrious Langport—enormous spikes—many raised locally. Cut the spikes as the first flowers open, and every bloom on the spike will fully expand and keep fresh for nearly three weeks even in summer.

Although the climate here is on an average 4° or 5° colder than in the south, their Hybrid Tea Roses, possibly from being budded on the *Manetti*, and subsequently rooting from the junction into the soil, are never killed in the winter; in fact, I observed a week since splendid blooms thus in the open. Here I may digress to say most of this firm's 100,000 Roses I observed were on the *Manetti* stock; and in a pretty long experience—Mr. Gilmour, junior, notwithstanding—I certainly never saw at the end of August such wonderful Roses, and, I may add,

such vigorous growth. I was not surprised therefore to find on my return from Scotland some days afterwards this firm had first prizes in every class open to them, against all comers, in Dublin. Possibly the close proximity to the sea at Strangford Lough has also a modifying influence on the temperature. Thus far I have referred to the outdoor stock for supplying cut flowers, without mentioning two of Messrs. Dixon's specialties for the same purpose—*Chrysanthemums* and *Dahlias*. Both, in their several sections, are grown by the thousand. As to the former—curious, the demand is chiefly for white flowers—incurved, Anemone, reflexed and Pompon, and the supply is selected accordingly. At Dublin Royal Horticultural Society's Show a few days since those *Dahlias* I see had also premier honours. Coming to the indoor department the stock is grown on commercial principles. Take the warm *Adiantum* house—there are but two of *A. farleyense* or *A. Pacotti* (very dense) to 1000 *A. cuneatum*, because the latter will "travel" and keep while the former will not. Another house has hardy Palms in small pots for table or room decoration. Another again similarly 2000 dwarf Tree Ferns, *Lomaria gibba*, handy seedlings in 3½-inch pots. So of *Asparagus plumosus*. Of this and Ferns an average of 500 fronds are required per week. The next long house was devoted to *Eucharis amazonica*, in splendid health. Very singular, neither Mr. Dickson nor any of the firm believe in the existence of the so-called *Eucharis* mite. "They never saw it," and think what passes as such is generated naturally after the bulbs have begun to decay, from a low temperature, or too much water, or both combined. Their enormous stock was certainly a picture of health. Again we come to a Fern house; this time the very handsome *Pteris serrulata* major, *Athyrium Goringianum*, and *Lastrea cristata*, being chiefly the tenants. *Lapagerias*, white and rose, are largely required, as well as *Stephanotis*, *Hoyas*, *Hibbertias*, and *Mandevillas*. Lastly, passing over the customary greenhouse occupants, and a large stock of *Bouvardias*, *Tuberous Begonias*, *Pelargoniums* of all classes, *Cistuses*, *Fuchsias*, *Gloxinias*, *Cyclameus*, &c., we come to one of the longest houses for forcing and early-flowering Tea Roses, for which the demand in the early months of the year seems insatiable. Here *Maréchal Neil* comes first, then Messrs. Dickson's own seedlings—*Pedigree*, *Miss Ethel Brownlow*, and *Lady Castlereagh*, both very vigorous and free flowering; the former bright salmon pink, shaded yellow; the latter an effective rosy yellow. It is remarkable that this last, *Lady Castlereagh*, is one of the few Roses never attacked with mildew—a fact worth noting.

Before exhausting your space, or your patience, I conclude with naming three sets of Dickson's new Hybrid Pedigree Roses. The first sent out in 1887 consisted of *Earl Dufferin*, *Lady Helen Stewart* (specially complimented in my hearing by the Lady Lieutenant of Ireland, the Dukes of Abercorn and Leinster, and a brilliant suite a few days since at the Dublin R.H.S. Show), and *Miss Ethel Brownlow*, now to be found described in all the Rose catalogues. This year Messrs. Dickson introduced for public favour *Caroline D'Arden*, H.P., a cross between *A. K. Williams* and *Marie Baumann*, and if possible superior to either parents—a pure, massive, soft rose colour. The other was *Lady Castlereagh*, a Tea already referred to. Both had first-class certificates in Dublin, Glasgow, &c. This enterprising firm hope to exceed their former triumphs next season with *Lady Arthur Hill*, peculiar pyramidal shape, vigorous, and in constitution and perfume faultless; *Jennie Dickson*, a wondrously promising beauty, and *T. W. Girdlestone*, all H.P.'s; and probably *Mr. Brownlow* and *Mrs. James Wilson*, Teas. As your correspondent I have to thank this enterprising firm for the facilities and courtesy extended to me on the occasion of my visit to their establishments in Belfast and Newtownards.—W. J. MURPHY, *Clonmel*.

HORTICULTURAL SHOWS.

RUGBY.—SEPTEMBER 4TH AND 5TH.

IN conjunction with the Warwickshire Agricultural Society's Show for the present year, a Horticultural Exhibition was held at Rugby on Tuesday and Wednesday, September 4th and 5th. A comprehensive schedule was provided, and the exhibits were numerous in most of the classes, three large tents being filled with Grapes, plants, fruit, cut flowers, and cottagers' productions. The latter were unusually good, and most creditable to the district. Specimen plants were not so numerous as in previous years, but the groups in competition possessed, unusual merit. That from Mr. J. Parker, Victoria Nurseries, Rugby, gained the premier award, and deserved the highest commendation for the good taste displayed in the arrangement. The foundation was chiefly *Adiantums*, with a background of Palm and Lilies, a few *Dipladenias*, *Lilium lancifolium*, and *Ixoras* being scattered about, with abundance of *Francoas*, the tall graceful spikes of which had a charming effect. Mr. T. B. Thomson was a close second with a well finished group, and Sir R. Moon was third for the brightest group of the three, but a trifle too flat, and wanting in finish at the margin. J. Marriott, Esq., had the best specimen foliage plants, including grandly coloured examples of *Crotons Andraeanus*, *angustifolius*, and *morte-fontainensis*. Cut flowers, fruit, and vegetables were all well shown, and the Committee, with their courteous Chairman, Mr. Linnaeus Cumming, and the Secretary, Mr. Arthur Mason, must be congratulated upon the success which attended their efforts to provide a satisfactory and representative exhibition.

BATH FLORAL FETE.—SEPTEMBER 5TH AND 6TH.

A MOST satisfactory Exhibition of plants, fruits, cut flowers, and vegetables was held in the Sydney Gardens, Bath, on Wednesday and

Thursday last week. Five spacious marquees were filled with exhibits, and in addition a building was devoted to stands of flowers, the vegetables being arranged on tables extending for some hundreds of feet along a terrace parallel with the railway which passes through the gardens. The entries were very numerous, and competition in some of the classes extremely keen. Altogether it was an admirable Show, but the heavy demands upon our space this week will not admit of a detailed report, and only a few of the leading features can be noticed. To the efforts of the Chairman of the Committee, Mr. J. Chaffin, and of the Secretary, Mr. B. Pearson, much praise is due for the satisfactory arrangements made for the convenience of exhibitors and visitors.

Plants.—Fuchsias, as usual, were excellently shown, grand conical or columnar specimens 9 to 10 feet high and 3 to 4 feet across at the base loaded with flowers had a most imposing appearance in one of the marquees, but owing to being arranged in double lines they could not be seen to their best advantage. Such specimens constitute a show alone, and nowhere else are Fuchsias now exhibited so well or so numerous, though they furnish a welcome change from the conventional stove and greenhouse plants that become such familiar objects to frequenters of horticultural exhibitions. The leading prizes were secured by Mr. G. Tucker, gardener to Major Clark; Mr. J. Lye, Market Lavington; Mr. Snell, gardener to Mrs. Counsell, Bath.

Stove and greenhouse plants were not quite so extensively shown as on some previous occasions, but Mr. J. Cypher, Cheltenham, was the most successful exhibitor, having neat beautifully flowered specimens in first-rate condition. Mr. G. Tucker and Mr. W. Jones of Newport, who followed in the class for twelve plants, also had some well grown examples. A globular specimen of *Schubertia grandiflora* from the last named attracted much attention, as it is rarely seen at shows. The flowers are large, pure white, and suggestive of a fine *Stephanotis*. With ornamental foliage plants Mr. Cypher was again first for large specimens; Mr. W. J. Mould, gardener to E. C. Bryant, Esq., Bath, and Mr. W. C. Drummond taking the second and third prizes in the order named. In smaller classes Mr. E. Wills, gardener to Mrs. Pearce, Southampton, and Mr. W. J. Mould were awarded prizes for foliage and flowering plants.

Ferns were largely represented, and a tent was exclusively devoted to them, constituting one of the most interesting features in the Exhibition. Colonel A. M. Jones and E. J. Lowe, Esq., two noted pteridologists, contributed liberally from their extensive collections of British Ferns, and they shared the majority of the prizes between them in those classes. Many rare and beautiful varieties were exhibited, and Colonel Jones in particular had a most elaborate collection of hybrid or cross-bred Ferns with their parents, and in some cases their descendants also. From this gentleman also came a large and beautiful non-competing group of Ferns occupying one side of the tent, and very conspicuous amongst the plants were the handsome varieties of *Scolopendrium crispum*, which formed a group at one end. Messrs. W. & J. Birkenhead, Sale, Manchester, also had a large group of healthy select British and exotic Ferns, which filled a stage extending the whole length of the tent on the opposite side from Colonel Jones's group.

Fruit.—A fine display of good quality fruit was provided, the substantial prizes offered having brought many competitors. With a collection of eight dishes (Pines excluded) Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, Warminster, secured first honours, showing three finely coloured bunches each of Alicante and Muscat of Alexandria, large Barrington Peaches, Hero of Loeking Melon, Moorpark Apricots, Washington Plums, Elruge Nectarines of rich colour, and Morello Cherries. Mr. W. Nash, gardener to the Duke of Beaufort, Badminton, was a close second; and Mr. A. Miller, gardener to H. W. Long, Esq., M.P., Rood Ashton, third. The class for twelve bunches of Grapes excited much interest, as though there were only two exhibitors the contest was a good one. Mr. Taylor, gardener to James Chaffin, Esq., Bath, was, after a short consideration, adjudged first honours for grand bunches of Alicante, Alnwick Seedling, Muscat of Alexandria (one bunch of enormous size), Gros Maroc of equally unusual size, Madresfield Court (handsome in bunch and berry but a little wanting in colour), and Black Hamburg. Some of these required a little more time to finish thoroughly, but they were magnificent examples of good culture, and well deserved the honours awarded for them. Mr. Pratt was second, showing Black Hamburg, Alicante, Muscat of Alexandria, Madresfield Court, Foster's Seedling and Lady Downe's, all of good size and colour, but not so large as the preceding. Mr. Taylor was again first with six bunches of Grapes, followed by Messrs. Nash & Gibson. The Black Hamburg and Muscat of Alexandria classes were well filled, Mr. J. Chalk, gardener to G. Read, Esq., Salisbury, and Mr. Coates, gardener to Mrs. Miller, Westbury-on-Trym, taking the lead in each class respectively. Peaches and Nectarines were numerous, first prizes being won by Mr. G. H. Richards, gardener to the Earl of Normanton, Somerley, Ringwood; Mr. W. Iggulden, gardener to the Earl of Cork, Marston House, Frome; and Mr. G. Pymm. Plums, Cherries, Melons, Pine Apples, and hardy fruits were all well shown.

Cut Flowers.—One large tent was wholly devoted to these, the display being much superior to anything of the kind hitherto seen at Bath. Gladioli, considering the season, were remarkably well shown. The first prize, for thirty-six spikes in not less than eighteen varieties, was won by Messrs. Kelway & Son, Langport, who had a grand lot, some of these being Dr. Benson, Dercyllus, Anthony Waterer, Orbit, Celestine, E. Scribe, and several fine novelties. Mr. S. Dobree, Wellington, was a good second, and Mr. G. S. Walters, Calne, third. With twelve varieties of Gladioli Mr. S. Tottle, Taunton, was first; Mr. R. H. Poynter, Taunton, second, and Mr. J. Mattock, Oxford, third, all having very

creditable stands. The first prize for twenty-four varieties of Dahlias was well won by Messrs. Keynes, Williams & Co., Salisbury, among these being perfect examples of W. Keith, Mr. Glasscock, Colonelist, W. Rawlins, Miss J. Ashby, Mrs. Kendal, Clara, G. Dickson, Mrs. Gladstone, and Harry Keith. Messrs. Heath & Son, Cheltenham, were second, and Mr. J. Nation, Taunton, third, both having capital stands of blooms. For twelve varieties Mr. T. Hobbs, Bristol, was a good first, the second prize going to Mr. S. Humphries, Kington Langley, and the third to Mr. H. Heermans. Single Dahlias were largely shown, the bunches in several instances being set up to the best advantage. For twelve varieties Mr. T. Truckle, gardener to T. Carr, Esq., was first; Mr. A. A. Walters, Bath, second, and R. Richards, Stapleton, third. Roses gave signs of having passed through much bad weather. Mr. Campbell, gardener to S. P. Budd, Esq., Bath, was well first for thirty-six varieties, among these being good blooms of Catherine Mermet, Captain Christy, Comte de Raimbaud, Star of Waltham, Mons. E. Y. Teas, Barthelemy Joubert, Heinrich Schulteis, Arthur Dickson, C. Lefebvre, and Marie Baumann. Messrs. Perkins & Sons, Coventry, were second, and Messrs. J. Cooling & Sons, Bath, third. The last named succeeded in winning the first prize for twenty-four varieties, Mr. Campbell being second, and Messrs. Perkins & Sons third. Mr. T. Hobbs was first for twelve varieties, Messrs. Heath & Son second, and Mr. W. J. Jones third. Several good stands of Verbenas were shown, Messrs. G. Cooling and Sons being first, Mr. J. Weston, gardener to the Rev. C. C. Layard, second, and Mr. J. Mattock third. With Zonal Pelargoniums Mr. J. Mattock was first, Messrs. Cooling & Sons second, and Mr. Cole, Bath, third. A remarkably fine lot of both German and French Asters were staged. With the former Mr. G. S. Walters was first, Mr. W. J. Jones second, and Mr. A. A. Walters third. For twenty-four French varieties Mr. W. J. Jones was first, Mr. Campbell second, and Mr. T. Evry third. The first prize for a collection of twenty-four varieties of choice cut flowers was awarded to Mr. G. Hobbs; Mr. J. Gibson, gardener to Earl Cowley, being a close second, and Mr. R. H. Poynter third. Special prizes were offered for a collection of cut flowers of hardy or herbaceous plants in not less than twelve varieties, and several remarkably interesting exhibits were arranged. Mr. A. A. Walters was first, Mr. J. Howse second, and Messrs. Heath & Sons third. Mr. C. Winstone, Clifton, was awarded the first prize in the class for hand bouquets, and fully merited it. Messrs. Perkins & Sons were second, and Mr. W. Brooks, Weston-super-Mare, third. For a table ornament, Mr. J. Cypher was well first, Mr. W. Jones being second, and Miss Lily Durbin third.

Vegetables.—These were crowded out from the tents, and had to be staged in the open air. In every class the competition was close and good, and rarely has such a capital lot of vegetables been seen together this season. The best collection of twelve varieties was shown by Mr. W. G. Pragnell, Sherborne Castle, who had excellent dishes of Veitch's Matchless Carrots, Autumn Giant Cauliflowers, Wright's Grove White Celery, Rousham Park Onions, Snowball Turnip, Giant White Runner Beans, Veitch's Prodigy Peas, Globe Artichokes, Ellacombe's Parsnip, Tender and True Cucumber, and Sutton's Satisfaction Potato. Mr. G. H. Copp, gardener to W. E. S. Erle-Drax, Esq., Sherborne, was a close second; and Mr. T. Wilkins, gardener to Lady Theodore Guest, Henstridge, a good third. Special prizes were offered by Messrs. Sutton and Sons, Reading, and for these there was a strong competition. Mr. G. Copp was a good first, having Sutton's King of the Cauliflowers, Duke of Albany Pea, Sutton's Seedling Potato, Wright's Grove White Celery, Perfection Tomato, and new Red Intermediate Carrot, all in first class condition. Mr. T. Wilkins was second; and Mr. S. Haines, gardener to the Earl of Radnor, Coleshill, third. Messrs. Webb & Sons also provided the prizes in a class for a similar number of varieties, and for these again the competition was very keen. Mr. G. Copp was first, staging in this instance very fine Webb's Snowdrop Potato, Sensation Tomato, Improved Banbury Onion, Duke of Albany Pea, Grove White Celery, and Webb's New Defiance Carrot. Mr. A. Miller was a very good second; and Mr. S. Haines third. For three varieties of Tomatoes Mr. J. Fortt, but it was doubtful if these could rightly be termed distinct. Mr. W. Strugnell, gardener to A. R. Bailly, Esq., Frome, was a close second, his varieties being very distinct and well shown. The best dish of Sutton's Perfection Tomato was shown by Mrs. W. Osborne; the second prize going to Mr. Richards, and the third to Mr. H. Prodgors.

Miscellaneous.—The non-competing exhibits comprised a magnificent group of cut flowers from Messrs. Sutton & Sons of Reading, representing hardy and half-hardy annuals, with Begonias and other plants. Such an effective display is rarely seen, and it attracted quite a crowd of visitors. Messrs. R. Veitch & Son, Exeter, had a large group of miscellaneous plants, as also did Messrs. R. Smith & Co. of Worcester; and Messrs. G. Cooling & Sons, Bath, had a beautiful collection of Tea Roses and Dahlias, the former uncommonly fine for so late a period in an unfavourable season.

OUTDOOR GRAPES.—These were so late in setting that it is doubtful if any will ripen this year. Where not badly affected with mildew they may ripen sufficiently to be utilised for wine-making. In any case it is unwise to neglect the Vines, as this may lead to a failure again next season. The laterals should be freely thinned, and those reserved stopped at one or two joints beyond the bunches. Also reduce the number of the latter where at all thick, this materially benefiting those left on the Vines. Neglect to thin out the wood and bunches, and neither will ripen. Stop the strongest young canes at a length of about 4 feet, and the weaker ones according to their vigour, all lateral growth being stopped at the first joint.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Earliest Forced House.*—The leaves are off or nearly so. To induce as complete a rest as possible the ventilators should be kept open constantly, and if the lights be moveable they may be withdrawn for a time. This will prevent undue excitement of the buds and have an invigorating tendency, especially as the border will become thoroughly moistened by the autumn rains. If the roof lights have been removed as advised in former calendars, they should not be replaced, but if they cannot be removed see that there is no deficiency of water at the roots of the trees, for though the impression prevails that dryness at the roots accelerates ripening of the wood, it is fatal to the development of the buds. The border should never be allowed to become dry at any time, but a much lessened supply of water will suffice when at rest than during growth. When the leaves have fallen the trees may be finally pruned. Only the strong growths that have not the points well matured should be cut back. In all cases be careful to cut back to a wood bud, not being deceived by a triple bud, as these in some instances form triple fruit buds, notably *Grosse Mignonne* and *Noblesse*. Ordinary attention having been given to disbudding, laying in no more wood than is necessary for the succeeding year's fruiting and for the extension of the trees, and removing fruited and other unnecessary parts after the fruit was gathered, very little pruning will be required. Thoroughly cleanse the house, and if the foliage has been infested with red spider or insect pests, dress the trees at once with an insecticide, as red spider will secrete itself in the rough portion of the bark and in the woodwork, applying the dressing thoroughly but carefully with a brush. If the trees have been badly infested it may be necessary to repeat the application before they are secured to the trellis. Remove the old mulching or loose surface soil, and supply fresh loam, having an addition of bonemeal and wood ashes in equal proportions to the extent of about a twentieth part. Partial lifting of weakly trees will be necessary, which should be done before the leaves have fallen, and in the case of trees that do not ripen the wood well, the roots should be carefully lifted and relaid in fresh compost near the surface, understanding that the drainage is perfect.

Succession Forced Houses.—Trees that ripened their crops in June will soon be casting their leaves, and should be treated similarly to those in the earliest forced house. Those that ripened their crops in July and August will now have the buds plumped, and the wood being ripe the roof lights may if moveable be removed so soon as the leaves give indications of falling, or towards the close of the month. If the wood does not ripen well keep the house rather close by day when there is sun, and open the ventilators fully at night. Any weakly trees that do not plump the buds may be assisted with liquid manure. Do not neglect the trees from which the fruit has been recently gathered, thinning out growths not required for future bearing, removing the bearing wood of the current season, ventilating freely, watering inside borders as may be necessary, and occasionally syringing the trees.

Late Houses.—Trees swelling their fruit will need the borders moist and mulched, and those with the roots in outside borders must not be neglected should dry weather prevail, and if carrying heavy crops weak liquid manure should be supplied. When all the fruit has been gathered remove the shoots that have carried the crop, and if the wood is not in a favourable condition as to ripening, gentle fire heat with a free circulation of air will be advisable; this more particularly applies to the late varieties. The midseason Peach trees will ripen the wood if the autumn be favourable, but if wet and cold they are benefited by gentle warmth and a free circulation of air.

MELONS.—Plants swelling their fruit will require considerable attention to guard against canker. Free ventilation, a little air being admitted constantly, with careful attention in watering and sprinkling, is necessary at this time of year, and affected parts should be rubbed quite dry with quicklime. Repeat the lime applications as may be necessary. Cracked fruits will need to be guarded against by the reduction of the moisture both at the roots and in the atmosphere. The temperature should be maintained at 70° to 75° by day artificially, which may fall to 65° in the morning. The house will need damping morning and afternoon when the crops are swelling, but only on bright days must the syringe be employed over the foliage, and that early in the afternoon. Earth up the roots of the later plants directly the fruit commences swelling, and feed with liquid manure or waterings through surface mulchings of sweetened horse droppings. Plants in pits and frames must be sparingly watered, and when necessary afford it early, so as to have the foliage dry before nightfall. Renovate the linings to finish off the crops directly the heat is found to be waning, and employ a covering over the lights on cold nights.

CUCUMBERS.—The temperature should be maintained at 65° minimum and 75° maximum from fire heat, with a rise of 10° to 15° from sun heat. Remove unhealthy leaves and old growths, stopping and training the others as may be necessary. Employ the syringe sparingly, only damping the foliage on bright days so that it may become dry before night. Damping will require to be done in the morning and again in the

evening. Pot seedlings as they become fit, and keep them near the glass to insure sturdy growth, pinching out the growing point of those required for covering low trellises at the second rough leaf; others train with a single stem, securing to a small stick, rubbing off the laterals to the extent of stem required to reach the trellis. Be sparing with moisture to plants in pits and frames, maintaining the temperature above indicated by linings renovated as required, closing early, and employing a covering of mats over the glass on cold nights.

PINES.—Young plants that have been liberally treated show at this season luxuriant growth, and as the influences inducing this are decreasing both in force and duration, it will be necessary to take steps to prevent the growth becoming soft and attenuated. A drier atmosphere should be maintained in order to consolidate the growth, employing fire heat when unfavourable weather prevails. Syringe occasionally early in the afternoon on sunny days. When water at the roots is necessary, give a plentiful supply of weak liquid manure at the same temperature as the bed. Keep the bottom heat steady between 80° and 90°. Attend well to the ventilation, closing the house at a temperature of 80°, maintaining the night temperature at 65°. Encourage plants on which the fruit is swelling with heat and moisture, the night temperature ranging from 70° to 75°, and in the daytime from 80° to 90°, closing at 85°. Plants for starting into fruit early in the ensuing year should be selected from those which were started last March, and be brought together about the end of the month, where they can be rested for about six weeks.

PLANT HOUSES.

Gardenias.—Cuttings for next year's plants should be inserted singly in small pots at once. Select soft-growing shoots for this purpose, but not weak growths. If they are inserted in sandy soil and kept close and shaded they will not be long before they are rooted. If a few large plants are needed select some of the best of those that are now a year old, and place them into 8 or 9-inch pots. Pinch the shoots from time to time, and the foundation for large plants will be laid. With this object in view the grower must be prepared to forego the blooms that the plants would otherwise produce. With good treatment two-year-old plants should be 3 feet through them, and in condition for yielding a large quantity of bloom. If the earliest plants that have been in an intermediate temperature are pushed forward in brisk heat they will soon form flower buds. Give plants that have about completed their growth more air for a time, which is more than ever necessary in a season like this to ripen the wood, for this is the secret of good flowers and plenty of them.

Cyperus distans.—For groups in rooms, halls, in fact any form of decoration, this is one of the most ornamental plants that can be grown. It can be propagated by division, but the easiest and quickest method is from seed. This plant seeds freely. The seeds are small and of a light brown appearance when ripe. It is only necessary to dry them for a few days before sowing. They germinate as freely and quickly as the seeds of ordinary grass. When the seedlings are large enough they should be pricked an inch apart in boxes and grown in heat until they show signs of crowding, then be placed singly in 3-inch pots. They must not be grown too warm or they will draw up weakly. If seed is sown now sturdy plants will be ready early in the year for 5-inch pots. They soon push growths from the base, and by July will produce five or six flower stems, when they are very effective. This plant is very liable to red spider, and therefore must not be grown too warm or stood upon a dry base. They need abundance of water.

Dracaenas.—All kinds, whether greenhouse or stove, that were raised from roots early in the year, should be placed without delay, if not already done, into 5-inch pots. The surface of the pots should be planted with *Selaginella* and *Panicum variegatum* intermixed. The latter should only be used for those that are retained in a warm house until they are needed for use. It is necessary to use rooted cuttings of *Panicum*. When the moss is established the plants will be better in an intermediate than a stove temperature.

Adiantums.—Plants that have been picked closely and kept cool for a few weeks should be placed into a temperature of 65°. They will quickly commence growth, and the temperature may then be gradually lowered to 60°, and will yield large quantities of fronds in the best of condition for cutting during the winter. As the fronds develop allow plenty of light to reach them, and give air daily to harden them.

THE BEE-KEEPER.

ADVICE ON BEES—A REVIEW.

"THANKS, Mr. Editor, for the advice given in your valuable journal. Since I abandoned the straw hive and the brimstone pit I have had a considerable quantity of honey."

The above may not be the exact words, but they certainly convey the meaning of many letters which appear in contemporary journals. More honey by abandoning the straw skep and brimstone pit! Did ever anyone hear such nonsense? The greatest takes of honey ever recorded were from straw hives; and as for the brimstone pit,

I have repeatedly shown that where bees are managed in a proper manner for profit they will increase, and what else can be done with the surplus than brimstone them after every bee-keeper has his proper number, and has learned how to maintain it and increase it, as it should be where profit is the aim? I can readily see where surplus bees can be saved under the present general system of management and mismanagement, but defy anyone to prove that either the straw skep, or the brimstone pit with all its horrors, tends to decrease the yield of honey. Mismanagement in many ways does this, and when failure takes place, as it does oftener than otherwise, the Editor again sagely remarks, "Your own fault," but cannot point the way to success. Let us take a serious view of two of the latest advices—namely on

UNCOVERING SUPERS AND CONTRACTING HIVES.

To uncover a super so as to lower the temperature of the hive at any time unsettles the bees and lessens their industry. Their work is instead of comb-building going on during the night time, to attend to keeping the brood warm and to daub the super over with propolis, and to have every chink filled with it, the result being an almost cessation of honey gathering because of the want of combs, which are generally made during the night, but with cooled supers can only be made during the day, while those that are so made are much discoloured by the extra crowding of bees necessary under the circumstances. Stupid as the above advice is, what are we to think of contracting a hive of ten frames to that of six? a size only about one-half a hive should be. But what is to be done with the four frames removed teeming as it should with brood we are not told. That will probably be a mystery to the adviser himself. I trust no bee-keeper will ever follow that foolish advice, but rather increase the size of the body of the hive at this important time as well as keep supers always well covered, so that a uniform temperature is always maintained.

We have had hives when provided with empty comb below gather 20 lbs. in weight daily. Had such hives been contracted instead of expanded they would not have gathered 5 lbs. daily, and yet this is the advice given by the wise men of the day to their unfortunate and misguided brethren who, if able to help their bees to gather honey, would also be in a fair way to make money. On these subjects I have often touched, and thrown down the gauntlet but none has accepted the challenge of—A LANARKSHIRE BEE-KEEPER.

BEEES IN THE WRONG PLACE.

I AM writing to ask you your opinion about some bees that have swarmed or rather made their home under the floor of my bedroom. It happened in this way. Twelve months ago last June a small swarm was seen to enter the air grating between my bedroom floor and the kitchen ceiling (which is under the floor). They seem to have gone in about 2 feet between the two joists. I did not attempt to get them out last year, but this year they have so increased that they become a nuisance, and what is more, being close to my front door, my children are not safe to go in and out. This last few days thousands of bees have been in and out. I believe they had honey a short time ago, but my impression is that they are being robbed by others, as some of them do not seem to know their way in, and they always seem so spiteful. What I want to do is to destroy the bees entirely, but how to do it am at a loss to know. I shall have to cut out the grating no doubt, as the bars are only wide enough apart to admit a bee. Any information respecting how to get rid of them will be thankfully received. We have plenty of bee-keepers about here, but none of them seem to know how to get the bees out, or what to advise me to do. If I pasted something over the grating and kept them in, how long would they live in that state, or would they die and cause a smell?—H. COSTER.

[In the above case the first thing to do is to ascertain the exact locality of the bees. This can be done by pushing an iron rod through the grating until it comes into contact with the combs, or by listening where the sound of the bees comes from, either by laying the ear to the floor or on a stick resting on it. After the right spot is ascertained, have a bee-keeper in attendance, and a tradesman with a gimlet and keyhole saw cut the flooring on each side beyond the combs, then by lifting it carefully the same boards can be laid again, or if desirable cut close to the joists where the combs are (as they will not be in more than one space), then they and the bees can be lifted out easily and transferred to a frame hive. The floor will be little the worse by this manipulation if the work is done properly.]

If the floor cannot be interfered with the bees can be brimstoned, and the safest way to do this in case of fire is to close up the grating except one aperture, blow in the brimstone smoke with bellows until the work of destruction is completed, or close the entrance entirely and bore a hole in the floor near the bees and puff smoke until the bees are killed; the small hole can be plugged up and will not injure the floor. There are chemicals that would destroy the bees if confined, such as cyanide of potassium, but this is dangerous. In such a dry place the bees would be thoroughly desiccated and no smell would arise from them, but a closer grating would be required to put in the wall, or the combs, unless removed, would attract other bees, and the trouble might continue for years to come.

Very likely the surmise about robbing is correct, and your letter unconsciously gives valuable advice. The spitefulness of bees is greatly increased when they find honey or sugar other than from flowers, and the nonsensical system of stimulative and outdoor feeding has the same effect. Bees in search of such sweets are very vicious, and sting readily a long way from their apiary. By closing the grating entirely the bees would undoubtedly die after some weeks or months, but that would be a cruel method of killing them.]

TRADE CATALOGUES RECEIVED.

Smail & Co., 22, Lime Street, London.—*Catalogue of Dutch and other Flower Roots.*

W. Drummond & Sons, 58, Dawson Street, Dublin.—*Autumn Catalogue of Dutch Flower Roots.*

Charles Turner, Royal Nurseries, Slough.—*Catalogue of Bulbs, Carnations, &c.*

Harrison & Sons, Leicester.—*List of Spring Flowering Bulbs and Roots.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Rose in Greenhouse (Subscriber).—You ought to have mentioned the name of the Rose that you erred in pruning. Perhaps the best thing to do now is to nip off the soft points of the shoots and let the other parts have all the sun and air you can to facilitate their maturation.

Small Worms in Soil (C. O. S.).—Letters arriving on Wednesday morning cannot be fully answered in the current issue. Give clear lime water, it will not injure the plants, and may be otherwise of service.

Dahlia British Emperor (W. R. Pierce).—The blooms were quite flattened in transit, but appear full and richly coloured. You should have sent specimens to the National Dahlia Show, or one of the meetings of the Royal Horticultural Society. The next will be held on the 25th inst. The Secretary's address is 111, Victoria Street, Westminster.

Twigs Falling from Yew Trees (J. A.).—The numbers of small fruiting twigs that appear to have fallen from the trees have perhaps been nipped off by squirrels, which are very mischievous at times. If there are no squirrels we are unable to account for the severance of so many healthy twigs, and the cause must be sought for on the spot.

Tulips for Sale (Weybridge).—We do not know the name of the sweet-scented yellow single Tulip to which you refer. The sweetest Tulip we remember is the Yellow Rose, but the flowers are double. The Duc Van Thol Tulips are the earliest, and thousands of them are sold in London about Christmas time. Others for sale may safely be chosen from catalogues according to the colours required and prices, the cheaper sorts answering as well as the more costly, the white Pottebakker, Chrysolora, Vermillon Brillant, with the red and yellow Keyzers Kroon are much grown, as are many others.

Peach Leaves Scorched (G. T. E.).—The Peach leaves appear spotted through the sun acting powerfully upon them whilst wet. Keeping the house close during the prolonged wet and dull weather would tend to make the leaf tissues thin, and on bright weather succeeding dull they would be unable to endure the sun, nor can such leaves perform their office of elaboration and assimilation. The older leaves

are cast as useless, whilst the younger, from being formed under more favourable circumstances, are retained. Their condition is entirely due to too close and moist an atmosphere.

Peristeria elata (*W. Bucks*).—You do very well in flowering so many Orchids in your "general utility house." *Peristeria elata* does not flower freely in a young state, but when it has attained sufficient strength it will flower freely, providing it is kept perfectly dry at the roots during the resting period. The flowers are produced from the side of its large pseudo-bulbs. If your plants are strong they ought to flower provided you ripen sufficiently their pseudo-bulbs. Possibly your house is rather too cool for their maturation. The *Tetramiera* should do well in the house, providing you suspend it in a light position from the roof. It is not difficult to grow and flower, and the conditions that suit *Sophranites* will suit it very well. If anything, it needs more sun to ripen it sufficiently. The flowers will be examined and named another week.

Potatoes Red Inside (*T. Shergold*).—Between the core and skin of a Potato is a sort of dividing line, generally about one-third of the half diameter from the surface or skin, and it is in this part that the red line in the specimen sent us appears. If the skin be very bright or deep in colour the internal line is proportionately so, but if the skin colour be pale, that of the internal line is fainter, if indeed there be any distinguishing colour worth note. Tubers formed at the surface are deeper in colour than those formed immediately beneath the soil. The lines are very decided in the surface tubers, but in those formed where due attention has been given to earthing with ameliorated soil there is no trace of colour in the tubers. The presence of colour is, therefore, due to the nearness or otherwise of the tubers to light. The colour is very decided in the cooked Potatoes, but disappears to a great extent after they have parted with the steam or water evaporated from them. This is a very interesting subject, and is due in both instances, in a great measure, to the presence or otherwise of light.

Tithe in Kind (*J. Burton*).—Curiously the same post that brought your inquiry as to when tithes ceased to be paid in kind brought us a book on the subject. It is entitled a "Key to the Tithe Question," by Rev. W. M. Hawkins, and is published by John Haddon & Co., Bouverie Street. We have not read it, but can see at a glance that it contains matter with which many persons cannot be expected to agree. We however cite what you want to know, and to which no one can object. "The tithe-tax was paid in kind down to the year 1837. The tenth pig, calf, cheese, milk, egg, sheaf, chick, Apple, Plum, &c. This was an exceedingly clumsy and unsatisfactory arrangement. It caused no end of ill feeling, strife, and conflicts. People are living now who have seen the farmer's men and the parson's throwing the turnip crop at each other, on the ground that the farmer had not fairly divided the crop, and was trying to cheat the parson. In the year 1836 an Act was passed to commute the tithe in kind to a money payment. In many instances this had been done by private arrangement from time to time, but after 1836 it was obligatory. The following is the introduction to the Act, written by John Meadows White, Esq., the solicitor attending on the Bill, published 1836:—'The object of this Act is to convert all the uncommuted tithes in England and Wales into a corn rent-charge, payable in money according to the value of a fixed quantity of corn, as ascertained from year to year by the average price of corn for the seven years ending at the preceding Christmas. The mode of making this conversion is, first, to find the gross average money value of the tithes of each parish for seven years ending Christmas, 1835; secondly, to proportion the amount of that value upon the lands of the several tithepayers; thirdly, to ascertain how much corn could be purchased with such amount; one-third of it to be laid out in Wheat, one-third in Barley, and one-third in Oats, at their average price ascertained by the weekly official returns of the price of corn for (in 120 markets) the seven years preceding Christmas, 1835; fourthly and finally, in every future year, to make payable the price of the same quantity of Wheat, Barley, and Oats, at the average prices, founded on a like calculation of the returns for the seven years ending at each preceding Christmas.'

Indian Figs—Cochineal (*Foreman*).—You are quite right in saying the fruit of *Opuntia vulgaris* is so called, but it is not that species that supports the cochineal insect. *O. vulgaris* has been naturalised in the south of Europe, where, in Sicily, it has spread over expanses of volcanic sands and ashes where not a particle of vegetable soil exists. The fruit is about the size of a Fig, and red on the inside; it is very much relished by some, but varies in quality according to the climate in which it is produced. The Sicilians grow it extensively, and esteem it one of their most valuable esculents. It forms an important article of diet with the inhabitants of that island during three months of the year, though strangers generally consider it insipid. In the countries where it grows, the Prickly Pear is, on account of its rapid growth, much used for the formation of fences round lands and dwellings; and the quickness with which it grows, and its long stout spines, speedily render it such a formidable enclosure that neither man nor beast can penetrate it. *O. Tuna* also makes strong fences; and when the island of St. Christopher was divided between the English and the French, three rows of the *Tuna* were planted, by common consent, between the boundaries. Sir J. E. Smith states that the long and slender stamens of the flower are very irritable, and that, if a quill or feather is thrust through them, in the space of two or three seconds they begin to lie down gently on one side, and in a short time become recumbent at the bottom of the flower. The fruit yields a rich carmine pigment, which is used at Naples as a water-colour. *O. cochinillifera*, or *Nopal*, is the plant on which the cochineal insect

feeds and breeds. It is in Mexico where the production of cochineal is carried on to the greatest extent, but it is also produced in the Canary Isles and in Java. The insect is the *Coccus cacti*. A number of the females are preserved during the rainy season; after the rains have ceased they are distributed over the plants; and, having deposited their eggs, speedily die. The eggs are hatched by the heat of the sun, and give rise to innumerable insects, the males of which are only in the proportion of one to a hundred or two hundred females, and, being provided with wings, they move about and fecundate the latter. After this period, the females, which before moved about, attach themselves to the plant, and increase rapidly in size, so that in the end their legs, antennae, and proboscis are scarcely discernible, and they appear more like excrescences on the plant than distinct animated beings. They are now gathered by scraping them off by means of a blunt knife, or brushing them off with a quill, a feather, a squirrel's or deer's tail, a few being left to continue the race. They are destroyed by dipping them in hot water, or by the heat of a stove. In the former case they are afterwards dried in the sun.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. Wilson*).—1, *Monarda didyma*; 2, *Centaurea montana*; 3, *Alstroemeria aurea*; 4, *Stenactis speciosa*; 5, *Actaea spicata*; 6, *Campanula Trachelium*. (*Reader*).—You should have sent a few particulars about the plants, no one can be certain of the names without some information. No. 2 resembles an *Aristolochia*; No. 3 the *Samphire*, *Crithmum maritimum*. No. 1 we do not even guess at.

COVENT GARDEN MARKET.—SEPTEMBER 12TH.

MARKET quiet, with little alteration. Plums lower.

FRUIT.

LANDLORDS' FARMING.

By the removal of superfluous hedges and the filling in of ditches we avoid the expense of keeping them in order, and really gain a considerable area of land in a farm of two or three hundred acres. A well-planned farm, with trim hedges, and every field clean as a garden, such as we see in the Lothians, is a pleasant sight, and such farms may be regarded as patterns or examples of neatness. But before all things we must keep economy and practical utility in view. Every fence or hedge is a source of expense, and therefore there should not be one more of them than is positively necessary. In Suffolk every hedge has its parallel ditch, often of a depth of 6 or 8 feet and half a rod wide. It is only an exceptionally strong current of water in winter that could render such ditches necessary, and two or three of them should suffice for the superfluous rain water of an ordinary farm. We are gradually filling in all superfluous ditches and clearing away the hedges.

In cultivation and cropping there should be no difference between the practice of landlord and tenant. Both have the same object in view, and there can be only one method by which that object may be attained. Thorough drainage, tillage, pure seed, timely cultivation, all must be of the best. But there must be no expenditure of time or money for the sake of mere appearance. We do not require anything upon a farm for mere show, but just sound useful animals, implements, and buildings. We know more than one home farm with its magnificent homestead upon which several thousand pounds has been spent, much of it needlessly. Plain, unpretentious buildings, which lend themselves to the convenience of, and real wants of the farmer, are what we require, and there should always be an engine-house, or covered shed for horse gear, for motive power for pumping, grinding, chaffing, and corn threshing. In certain extensive repairs of homesteads which we have had in hand for the last three or four years, not a penny has been spent upon anything like ornamental work. Take, for example, a homestead of which the repairs were finished recently. The farmhouse, an old picturesque monastic building, with walls 2 to 3 feet thick, had so faulty a roof that it had to be re-tiled, the woodwork was painted, and that was all that was done to the exterior; all interested suggestions of dressing the brickwork, a facing of stucco, colouring, &c., by the builder being quietly ignored. A moderate expenditure of paint, paper, and whitewash rendered the interior comfortable, and there was an end of the work. The barn, stables, piggeries, cow and cattle sheds, were simply restored to a sound condition, the yard enclosures, fences, and gates repaired, and a thorough coating of tar given to them and all exposed woodwork.

Buildings so restored to what is known as tenantable repair are done in the mutual interest of landlord and tenant. We often have reason to regret finding so many thatched buildings at old homesteads, which involve landlord and tenant in a periodical outlay for repairs, the landlord paying for the work and the tenant supplying the straw. Whenever it is possible corrugated iron is now used in preference to thatch, slate, or tiles, but it must not be forgotten that the rafters of an old roof are frequently unsuitable for covering with corrugated iron. A sound roof and floor are alike important for every farm building, and there can be no doubt that floors of asphalt or Portland cement kept thoroughly clean are an excellent preventive of swine fever.

It is in the animals of the farm that a landlord should do what is possible to set an example to his tenants. As a landlord's representative we do what we can in this direction,

and unquestionably very much can be done for the improvement of ordinary live stock on a farm. Perhaps sheep are the most important, because they are the most profitable, and we find it answer best to keep select half-bred ewes, and to cross with Hampshire Downs. We have just purchased some excellent lamb tups of that breed at £5 a piece, using one for each fifty ewes. Of pigs, we find it answer well to have cross-bred animals, a medium Yorkshire and a Suffolk giving us excellent pigs. As we have said before, we regard pure bred Tamworths as likely to prove most suitable for the London market, for which porkers of 50 lbs. weight and not fat are required. Of cows a cross-bred animal between a Guernsey and Shorthorn is that which gives stock alike superior for the dairy or butcher. We know Guernseys are not easily to be had, but this difficulty is to be overcome, and it is quite worth while to take sufficient pains to secure a cross that has proved to be so profitable as this.

WORK ON THE HOME FARM.

Hardly a day passes without rain, and harvest work drags its slow length along. Wheat is being carted, and many stacks are finished and thatched, but the grain is not really hard, and very little threshing will be done till after Christmas. It is something to save the corn at all in such unsettled weather, and so far, we believe, we shall have a bright, full sample of Wheat when we do thresh it. Barley is sadly discoloured, and good malting samples will be rare and costly; fortunate indeed will be the farmer who has them. Those who have a large breadth of Wheat will very likely find it answer better than Barley. We are now fast getting down the latter crop, for it is ready and must come however unfavourable may be the weather. All sorts of reports are rife about harvest work and prospects, many of them being very nonsensical. It is undoubtedly a difficult season, and work makes slow progress, but we do not find it more costly than it has been in other years. If we in the southern half of Great Britain despair of a successful harvest, what do northern farmers say whose corn is still green and full of growth? Yet every field and every crop affords evidence of first-class practice, and a stout effort to overcome adverse climatic influences.

If only we had a favourable change of weather the bulk of the corn should be in stack in the course of another fortnight. In any case much of the Barley will require care after it is mown, for the young layers have in many fields almost overwhelmed it, and it will have to be turned and exposed to sun and air to harvest it. Much care is required for this work in such unfavourable weather. Already have we heard of heating in Wheat stacks, nor can it be wondered at, for the bottoms of the sheaves contain so much green growth of weeds that heating is inevitable where stacking is done early. Yet what are farmers to do? If the Wheat is left out in the fields till the weeds are dead there is no small risk of sprouting grain, and it is just a choice of evils. If Wheat can be got into stack in a suitable condition in any favoured locality it will probably command a high price.

HAY-DRYING MACHINE.—Would you kindly favour me with the address of the inventor of the hay-drying machine. I think his name is Gibbs.—W. M.—[We do not remember the address desired. Perhaps some of our readers may be able to supply it.]

REMARKS.

2nd.—Overcast and showery all day.

3rd.—Overcast in the morning, bright till 3.30, then heavy rain to 4.30, and damp afterwards.

4th.—Cloudy early, fine bright day, dull evening and night.

5th.—Rain in the small hours, cloudy all day.

6th.—Dull and drizzling till noon, then fine and bright.

7th.—Generally bright, with occasional showers.

8th.—Bright morning, fair afternoon, spots of rain in evening.

A showery and rather dull week. Temperature about the average.—G. J. SYMONS.

GUMMING IN FRUIT TREES.

GUMMING differs from canker in being attended by a discharge, the sap of trees where gumming is present abounding in astringent constituents. In canker the parts affected are rarely ulcerated or accompanied by a discharge, the sap containing a quantity of free acid. Canker, however, is a form of extravasated sap, mainly confined as regards plants cultivated for their fruit to varieties of the Apple and Pear. If there be no discharge in canker there is an enlargement of the vessels of the bark at the commencement of the malady. The attack is almost invariably accompanied by a swelling, largest in the Apple, and to a lesser extent, yet always present in an attack of the disease on the Pear. When Elms and Oaks are affected sometimes no swelling occurs, and in true canker of the Peach it is not preceded or accompanied by swelling of the affected parts. Extravasation, therefore, in canker is internal, and there not being any discharge it is proposed to exclude it from this investigation.

Gumming is confined for the most part to the Peach, Nectarine, Plum, and Cherry. Almonds and Apricots are also affected by gumming, and so also are many other trees whose exudations are gummy or resinous. Whatever may be the predisposing cause of the rupture of the sap vessels and the resulting discharge, the substance formed is gum quite as much so as gum arabic or gum tragacanth, only differing in character with the producing subject, though many of the resins and gum resins are not produced by disease. The disease known as gumming is, according to scientists, highly contagious, and is caused by a fungus named by Professor Oudemans *Coryneum Beijerinckii*. The fungus by its mycelium develops a ferment, penetrating the cells and transforms the contents, particularly the starch granules, into gum. One peculiarity of the ferment is its penetration of living cells—viz., those of cambium, and changing or modifying their protoplasm, forming tissues with new properties. The tissue so formed sooner or later secretes the ferment and changes the cell contents into gum. A singularity of the disease is that the fungus causing it cannot penetrate the bark. Laceration, at least abrasion, of the bark must take place before the germs can enter. That or those are common injuries arising in Nature and culture. "But," asks Plowright, "how do the spores which are undeveloped in the viscid gum gain access to them? They cannot be blown there by wind is obvious. If the gumming occurs upon the upper branches (which is rarely the case) of course they may be washed down by rain or syringing; but how do they spread from tree to tree? Obviously, they must be carried—most probably by insects." Unquestionably. Why not ants? They usually swarm about trees liable to gum, and they quickly find out any abrasion or lacerations of the bark caused by trimming the trees, nailing or tying the growths, evidently relishing the juices of the trees so unsealed; indeed, they revel on plant and insect secretions.

Happily the disease never attacks healthy trees. Ants or insects of any kind may visit abrasions and lacerations without gumming resulting. The virus may be abundant in one tree without danger of its spreading next if it is healthy. The fungus seems impotent until the host plant presents a fitting nidus. It is not enough to introduce gum virus, abrasion and laceration are equally ineffective; disorganised tissue must exist before the fungus can spread. Plethora, or that state of a plant's excessive

vigour in which the sap is formed more rapidly than the circulatory vessels can convey it away, must have been induced, and when that occurs rupture is inevitable. Fungus may be brought by insects, and so gain free ingress by reason of the rupture. If so, is it a cause or effect? Scientists insist (and rightly) that if there were no fungus there would be no gumming, and it is the cause of the disease. Keep the fungus away, and what? The tree will make a clean and healthy growth, perfect fruit buds, storing food in well ripened wood for the insuring of good set, a satisfactory stoning, and perfecting of a profitable crop of fruit. The fact is the other way, for the fungus can no more be kept from attacking a tree in a condition favourable to its existence than a healthy tree can be kept from effort at reproduction. The fungus, therefore, is not to the cultivator a first, but an after consideration, consequently it need not cause anxiety when the curriculum of treatment is not such as to create disorganisation of the host plant's tissues—a necessity of the fungus which scientists, if I understand their meaning rightly, do not question. Fungoid disease can only subsist on food essential to its perfecting, which depends on destruction or change of the elements appropriated to its use. If the scientist pins his faith to the fungus as the sole cause of the disease it is allowed that the disease is more likely to attack trees under certain conditions, and its virulence corresponds in degree with the elements or material available for transforming into gum. On attack, a tree in ill health will suffer more from the effects of the disease than one more healthy. In combating the disease the steps taken are preventive and remedial. The first are directed to sanitation and other precautionary measures essential to the health of the tree liable to attack, or avoidance of the agent by which the disease is fostered.

A knowledge of the disease is of primary importance in assigning predisposition and inherent tendency a place. Predisposition may arise from various causes, but the chief is over-luxuriance, whether induced in trees favoured by Nature through soil and climate, or culturally by soil too richly manured. Soil exerts considerable influence in the predisposition of trees to gumming; the least disposition to the disease is on the oolitic formations, and greatest on alluvial. Siliceous soils favour the disease more than clays. Inherent tendency is obviously resolute into the agency by which perpetuation or reproduction is effected. The disease is common enough on natives of the genus *Cerasus* and *Prunus*, induced perhaps by a period of moist warm weather followed by cold, the sap being then in excess of the evaporation, and the circulatory organs become disorganised, the sap stagnates and contracts, and rupture follows on a return of milder, milder weather. Culturally, plethora is induced by location and condition of soil, and by cultivation itself, of which instances may easily be observed in most gardens; but we must look a little closer if we are to make any real effort in eradicating the disease, and begin at the beginning.

The disease, as before stated, is common to wild as well as cultivated trees. The predisposition is natural, and the inherent tendency coherent. It prevails largely on Sloes and wild Cherries; indeed is common to all the species and their varieties, cultivated or otherwise, of the genus *Cerasus* and *Prunus*; therefore it is a necessity to remove these from the neighbourhood of an orchard or fruit garden, since the disease-producing insects and fungoids are fostered by them, consequently certain to spread to ill cultivated trees of kindred affinity. Perhaps no tree is more subject to lose large branches from disease than the common Laurel, which is very common in the immediate vicinity of fruit trees in private gardens, and many other species and varieties of the Plum and Cherry family are planted to form ornamental and sheltering belts or shrubberies about gardens, and not infrequently adjoining the fruit tree quarters. They are unquestionably useful as shelter, but it does not alter the fact that a whole fruit garden of flourishing trees may be ruined in a few years by the injudicious introduction

into an adjoining border or shrubbery of such questionable trees as Almonds, Cherries, and Plums. The blossoms are lovely, no doubt, but greater "sinners" in respect of gum it is not possible to find. They are forced into growth by the free root action of the stocks on which they are worked and the result is plethora, and concomitantly most, if not all, the insect and fungi diseases to which trees cultivated for their fruit are liable.

The stamping-out process needs carrying further. No stock should be used which is originated from stone, sucker, or layer of a diseased parent. That may be impracticable, but there is a difference between propagation from a stock that exhibits traces of disease and an apparently healthy one. It is not sufficient to make sure, so far as careful selection can make it, of healthy trees for stocks, equal care must be exercised in the selection of buds and scions. G. ABBEY.

(To be continued.)

TOMATOES IN WINTER.

OUTDOOR Tomatoes are particularly scarce this year, and all that are nearly ripe on the approach of frost will doubtless be gathered and suspended in warm houses. That fruits cut in a green state and ripened in heat are scarcely so good as those left on the plants till nearly or quite ripe I readily admit, and in any case it is advisable, where possible, to grow a few plants for fruiting during the winter and till more are raised and fruited next spring. Those who, like myself, anticipated a failure in the open, will have, it is hoped, taken more care of any plants they may have under cover, and also forwarded more in pots ready for placing under glass in close succession to exhausted Melons and Cucumbers. We had a few late-raised seedlings which, about the middle of July, were shifted into 13-inch pots and set in a sunny position. Early in August half of a Cucumber house was cleared and the Tomatoes introduced. The growths were thinly trained over the roof and all side shoots kept rubbed out. At the present time several fine clusters of fruit are set on each plant, and, all going well, plenty of good fruit will be cut from them throughout the winter.

Tomatoes, in common with winter Cucumbers, are all the better for having a good and early start, and rather than have to commence now with young plants newly struck, or seedlings, I would much prefer to put new life into a few old plants in pots. These may be freely cut back, this inducing the formation of numerous strong young growths, which soon arrive at a bearing state. A shift into fresh pots is not necessary nor advisable, but much of the old surface soil may be picked away from the roots, and good turfy loam, with old Mushroom-bed manure in equal quantities, and a liberal addition of superphosphate of lime, added. If the start has to be made with either cuttings struck in gentle heat or seedlings, they may first be potted off in pairs in 6-inch or rather larger pots, and from these, before they are drawn or root-bound, shifted into 12-inch or rather larger pots. A moderately good loamy compost, or say a mixture of two parts turfy loam to one of either leaf soil or old horse-droppings, best suits them, and they ought to be potted rather firmly, a good space being allowed for a top-dressing later on. In whatever manner the plants are prepared, or whether old or young plants, it is unwise to plant them in a rich mound of soil, as much heavier crops are obtained from plants in pots set on a bed of fairly rich soil. Either old Melon or Cucumber beds are capital sites for Tomatoes in pots, the latter being set nearly on the surface, or only just deep enough to bury any side drainage holes there may be. The roots soon take possession of the food supply in the bed, while the pots act as a check to rank unfruitful growth. Any without this available rich root-run will require much more liberal treatment in the way of top-dressings, plenty of water and liquid manure, and if well attended to in this respect will produce remunerative crops.

It is not from want of good attention, however, that many fail with winter Tomatoes, but rather from being over-zealous. They either give too much heat or too much manure, or perhaps the two together, the result being very rank or very abundant growth, accompanied with few or no fruits. Near to the glass the plants ought always to be grown, and thinly, and on no account should much manure be given at the outset. First get a good crop set, and then feed away to your heart's content is my advice and that of other experienced men. There is no real necessity to confine a plant to a single stem, especially when the roots have access to a bed of soil and manure underneath. On the contrary, several branches may be laid in provided each has good space and is kept free of all side shoots. These main branches ought to be trained fully 12 inches apart, and supposing the plants are set near the centre of a long

low roof, as in our case, the shoots may be taken both up and down from the same plants. When it is desired to grow Bouvardias, Poinsettias, forced bulbs, fine-foliaged plants, Ferns, or other plants under the Tomatoes, the main branches of the latter ought to be trained not less than 18 inches apart, and if rank foliage is formed this also should be slightly reduced in size, or everything underneath will be unduly shaded. In any case all superfluous growth should be removed as fast as it forms, but it is unwise to stop the leading growths while there is roof space that may be covered.

Many persons succeed in covering their roofs with fine healthy plants, every detail but one being well understood. Where they err is in maintaining a higher temperature than is needed or suitable for Tomatoes. Stewed up in a house more suited as far as temperatures are concerned to Pine Apples, the trusses of flowers are certain to be weakly and devoid of pollen, and a good set is an impossibility. The other extreme, or a greenhouse temperature, is also to be avoided. We find a fairly well heated house is needed, much the same amount of fire heat being given as ordinary stove plants are supposed to require. This, however, must be accompanied with air, little or much according to the external temperatures, some being left on all night in mild weather. This favours the production of strong flowers, and which if smartly tapped towards mid-day, or even syringed, rarely fail to set. At the present time not less than 9 inches of top ventilation is left on the Tomato house every night, but less will be given in colder weather or when we wish to forward the fruit more rapidly. I am no great stickler for very regular or even temperatures either by night or by day in the fruit houses generally, but always prefer to let them drop somewhat rather than heat the pipes excessively. I hold that the temperatures for Tomatoes may safely range from 45° to 60° by night with an increase in the daytime of from 5° to 10°. A house kept at these figures does not need to be damped down often, nor the plants syringed in order to keep down red spider. If the most troublesome pest, a small white fly known as *aleurodes*, is prevalent, nothing but frequent and gentle fumigations will rid the plants of it. When fumigating care must be taken not to use too much hot coal or coke in starting the smoke, and on no account should it be allowed to burn strongly, or all the flowers expanded and perhaps some of the buds will be crippled.

I have tried a considerable number of varieties for winter culture, but found none to set so well as the old Red and Dwarf Orangefield. Other corrugated or ribbed varieties generally set more regularly than the smooth round-fruited Tomatoes, but if good plants of any of the latter are available I would unhesitatingly start with them rather than wait longer for the more sure setters. Hackwood Park, Carter's or Sutton's Perfection, Dedham Favourite, Webb's Sensation, Hathaway's Excelsior, or any other favourite variety can be made to produce good crops of fruit, these being of excellent quality and certainly more handsome in appearance than the ribbed varieties. The smaller Plum-shaped varieties, though good croppers, are not nearly so profitable or so good in quality as the varieties I have named.—W. IGGULDEN.

AN EXPERIMENT WITH EUCHARIS

GRANDIFLORA.

I HAVE a good number of rather fine plants of this favourite flower, and when I took charge of these gardens last spring twelve-month I found the plants all in good health, and had apparently been well cared for by my predecessor. I, however, was told by my employer that six of the largest plants, purchased at an auction sale some years before, had failed to flower even once since they had been in his possession, though the other younger plants flowered fairly well. Of course, being a "new comer," I was asked the reason of the failure, and could only suggest a cause at that time. Some gardeners to whom he had shown them pronounced them a bad sort, as if there were worthless examples of this *Eucharis* in cultivation, a circumstance I had not before heard of. However, I found that the usual treatment failed to induce these six plants to flower, and therefore decided on the following experiment.

The plants were shifted from the stove to the temperature of an intermediate house, and in a fortnight to that of the greenhouse for a like period, then finally placed outdoors under the shade of some standard Apple trees. An hour or two's sun reached them both in the morning and afternoon. There they remained for two months, or till the end of August. The pots stood upon boards laid on coal ashes, so that the little water they had could freely pass away, and beyond the leaves losing some of their dark green colour I could not perceive any injury arising from this somewhat severe treatment; but certainly the plants did not grow, although the weather was warm and dry. In the meantime I had been preparing a house for winter Cucumbers, in which was a bed of

manure and leaves for bottom heat. When this was ready the plants were taken there and for a time placed on the bed, and afterwards half plunged in it. They were carefully watered and given liquid manure twice a week, also syringed daily. After a few days it was surprising to see how the plants revived, and it was not long before I had the satisfaction of seeing flower spikes appear. Altogether there were twenty-one spikes of four flowers each, and nine of three flowers, or thirty altogether. This summer the plants have been treated in a similar way, but with two weeks less time outdoors owing to the cool and damp weather, and they have even flowered better, for they have produced thirty-seven spikes of bloom, all large and perfect flowers.

I attribute the cause of failure, in the first place, to the plants being overpotted in their young state, the size of pots being what are called sixes; and secondly, from their not having a perfect and lengthened period of rest, a condition much more difficult to secure with plants in large pots than in smaller sizes, and I think it has been well proved that the *Eucharis* will flower more freely and at regular periods when the pots are both full of bulbs and roots, even if the latter are almost in a cramped condition, provided the plants are well supported by a suitable amount of heat, moisture, and stimulants; but in this case I concluded that nothing less mild than an enforced cessation of growth, brought about by the treatment described above, having due regard for the health of the plants, would attain the object aimed at, which proved to be successful. I should like my readers to bear in mind that I do not put this before them as a mode for general adoption, because the *Eucharis* can be successfully grown and flowered without it, but it is well to know that this plant, though a heat-loving one, will bear something different than the orthodox treatment, and, as in this instance, with satisfactory results.—THOMAS RECORD.

SMALL BORDERS FOR VINES.

On page 218 "W. S." records interesting experience on growing Vines successfully in small borders. That large borders formed of "elaborate mixtures" have proved satisfactory to the makers of them, healthy Vines and fine Grapes resulting, goes without saying; yet it is questionable if there are not as many failures as successes if we take a broad glance of the subject. There can be little doubt that a great deal of money and labour have been expended in making Vine borders that might have been saved with advantage to the owner, gardener, and Vines. No one can travel far or inspect many gardens without being conscious of that fact, though he may and will come across excellently grown Vines and splendid Grapes now and then, the outcome of care in border preparation and good general management, especially the latter, because it is certainly true that one gardener will grow far better Grapes on Vines in what is regarded as an inferior border than another will when the most costly and elaborate provision is made for their roots.

Some soils are naturally unsuitable for Vine culture. They may be too dry and poor on the one hand, or heavy and wet on the other. But the poor can be made rich and the heavy porous by suitable additions, without clearing the entire mass away to a depth of 3 or 4 feet, and a width of 5 or 6 yards, filling the whole huge chasm at once with turfy loam carted a distance of perhaps two or three miles or more, with other mixtures considered essential for the purpose in view. The latter plan may answer, has answered, and it certainly ought to answer, but it has nevertheless often failed. It can scarcely be doubted that tons of soil have been carted out of gardens and tons more brought in, while that introduced has not been so good for the purpose as that turned out. The new may answer for a few years or it may not, for it is quite a mistake to imagine that all kinds of turfy loam remains so, for the turf decays, leaving often a close bed of silt. A narrow border of good sound wearing soil is, as a rule, much better for Vines than is a needlessly deep and wide bulk of "turfy loam," so much of which is essentially and quickly perishable.

It must be known to many that large new borders made at great labour and cost have not been satisfactory. I have assisted in making some and in clearing them out again, the experience teaching a lesson that was not entirely lost. In one instance a "splendid" border was made 4 feet deep, 7 yards wide, and 60 long, all the old soil wheeled out and new brought in. It would have been better if the old had not been touched, or at least if a barrowful of it had not been removed. This was proved to demonstration, for a Vine was "stuck in" at the end of the house in the natural soil, a narrow strip 2 feet wide between the wall and the walk, and that Vine produced more than thrice the weight of Grapes than any other Vine in the house did over a series of years, and it was notorious that those on Vines in the regular border shrank seriously while the other did not. Soil

that will grow a heavy crop of Potatoes of the first quality will grow good Vines and Grapes, provided it is kept fertile and the Vines properly watered and tended; and the narrower the borders are in reason the more are the roots under control and the better they can be supplied with the right kind of nutriment for absorption.

One or two instances of superior Grapes being produced by Vines in narrow borders occurs to me. Some fifteen years ago Mr. James Douglas grew excellent Grapes at Loxford Hall. I remember inspecting them with much pleasure, and have a clear recollection that the best crop of the best Muscat Grapes was produced by a Vine that had been planted in a walled-in space, perhaps a disused tank. I forget its exact nature, but remember the dimensions of the enclosure were 5 feet long, 3 feet wide, and 3 feet deep. The Vine was trained horizontally along the base of the rafters, and three rods taken up the roof. There was not a great bulk of soil it will be conceded, yet the crop of Grapes on the three rods excelled that produced by any other Vine with ten times more space for the roots. How long the confined Vine remained bearing so well I have no means of knowing, but it could doubtless have been kept in a satisfactory condition for many years. If Mr. Douglas sees these lines he will not dispute their accuracy, and he may perhaps tell us how long the Vine was profitable.

When Mr. Denning was in charge of Lord Londesborough's garden at Norbiton he grew as good Black Hamburgh and Muscat Grapes as were to be found in most gardens, and much better than in many. I remember being impressed with the narrowness of the borders, those in two of the houses, if not more, not exceeding 3 feet in width, yet the Vines reached the top of an 18 feet or 20 feet roof, producing first-class Grapes for I do not know how many years. Rich strong soil it may be supposed was provided in the narrow borders. What it may have been below I am not able to say, but this I know, I never before nor since observed so much sand on and near the surface of a Vine border. When it was moved it was found to be quite full of white roots, not fat and thick like the underground stems of couch, but small and multitudinous. It was evident that the sand, possibly by the force of resistance, caused unusual subdivision of the roots. "Vines like sand," observed the cultivator, "and do not often have enough of it." Whether they like it or not, there is this to be said about it, that something they undoubtedly do like, in the form of liquid or solid manure, can be given freely where sand abounds without souring the soil; and there is very little doubt that a liberal addition of sharp sand to Muscat Vine borders that are composed of close heavy soil would improve them considerably. In the case in question three things were so apparent that they could not be ignored—small borders, much sand, and fine Grapes.

In the Royal Horticultural Society's gardens at Chiswick the best Grapes are grown in a border that was not made with new soil after clearing the old out. That method would have been costly, and it is practically certain if it had been carried out the Vines would not have worn so well as they have and be in the satisfactory condition they now are. The natural soil was not removed, but some fresh, a thickness of 5 or 6 inches perhaps, spread on it and worked in in trenching, as if in preparation for a fine crop of vegetables. That, with surface dressings of rich manure in summer for keeping the roots in the right place, and affording support when they were the most active, and it was most needed, have enabled increasingly valuable crops of Gros Colman Grapes to be grown—not huge exhibition bunches—but just the samples that realise good prices in the market. The border is perhaps 6 or 7 feet wide. The Vines have been bearing for some years, and are this year in as good condition as they have ever been, if not better, and they would soon be much better still if they had more room for extension. They are crippled, as the garden is generally, and it must be still further starved if the managers of the Society, whoever they may be, are content to go on losing money over that precious drill hall at Westminster.—SPECTATOR.

NOTES ON GLADIOLI.

AT THE CRYSTAL PALACE.

It has been asserted by some writers that the present season is, as far as the *Gladiolus* is concerned, no later than ordinary ones, but the Show at the Palace sufficiently proved how erroneous this was. Neither Messrs. Harkness & Sons of Bedale or Mr. Campbell of Gourock, both of whom generally exhibit so well there, were able to be present; indeed the latter grower wrote to me to say that he could not possibly exhibit before the Manchester Show on the 21st, while as far as my own flowers are concerned, I know that while I had the greatest difficulty in getting my eighteen, from the fact that my flowers were not one-tenth of them in bloom, my difficulty last year was to

save that number, as they were all gone out of bloom. There were but two exhibitors in the nurserymen's class, and one of these, Messrs. Kelway & Son, did not compete, although I believe their flowers had been entered for competition. Mr. Burrell had thus all the field there to himself, but he would have required a very strong exhibit indeed to have run ahead of him. There is a size and solidity about Mr. Burrell's flowers that one looks for in vain elsewhere, and shows the excellent quality of the soil in which he grows his bulbs, and also the suitability of his climate. His stand, while comprising many named varieties of French origin, also had a number of seedlings of his own, some of which were of peculiar beauty, and quite equal to the best of the French sorts. Of these latter he had *Primatrice*; *Pactole*, an excellent spike of this beautiful yellow variety which it is not easy to catch in such good form, as it has a tendency to open its flowers irregularly; *Flamboyant*, with large scarlet flowers; *Atlas*, a very long spike of light coloured flowers; *Bicolore*, a very striking variety, the upper petals brilliant rosy salmon colour, and the lower petals ivory white; *Celimene*, orange red, flamed with vermilion red; *Enchanteresse*, a splendid new French variety, very large flesh-white flowers, and a small feather of violet (this is without doubt the finest flower of recent years, and so highly did the Judges think of it that they awarded it a first-class certificate); *Grand Rouge*, a magnificent flower of intense scarlet, very like the old flower *Meyerbeer*, but very much larger and earlier in flowering, being one of the early section, and *Meyerbeer* one of the latest; *Rossini*, a fine old flower, and one of the most staying flowers that I know, dark red amaranth in colour, with white spots; *Archduchesse Marie Christine*, rather a loose flower; *Mabel*, a very beautiful well-formed flower, white, with brilliant carmine streaks; *Cervantes*, bright rose streaked with carmine, white line on petals; *Colbert*, cherry red, tinted orange; *Démosthène*, bright rose flamed carmine, white stripes; *Crepuscule*, a grand spike of lilac rose carmine, flushed with carmine. Besides these he had some excellent seedlings of his own, one, *Snowdon*, without doubt the finest white in cultivation; in fact, there has always been a scarcity of pure white *Gladioli*. *Madame Desportes* is of such a delicate constitution that no one can keep it. *Ondine* is too small for present taste; the same may be said of *Norma*. *Shakespeare* is good, but too early for September show, but *Snowdon* is very far in advance of any that we have; it is very like in form, size, and substance to *Enchanteresse*, but is of the purest white instead of creamy white, and is unquestionably destined for a premier place amongst *Gladioli* growers. Then there was *Nobilis*, a very fine flower of excellent qualities; *Ruddigore*, brilliant scarlet, very good; *Dorothy*, violet, shaded with lilac; *Pleasaunce*, beautiful soft rose, something like *Delila*, but deeper in colour.

Mr. Kelway's lot contained, comparatively speaking, but very few named varieties beyond those of his own raising. He had also several new ones which he had put up for certificates, but unfortunately he had not entered them, and so they were passed by. Amongst his flowers I noticed Mr. Baines, orange carmine, with carmine stripe on the lower petals; *Agonis*, salmon pink, flaked at the edges with vermilion, creamy-yellow centre, good flower; *Mannis*, orange red with violet tinge; *Lord Rothschild*, scarlet crimson shaded with purple; *Mrs. Langtry*, white, tinted with purple; *Rembrandt*, cerise, flamed carmine; *Bacon*, scarlet, dark violet centre; *Cabel*, very like *Mabel*, perhaps it was a mistake in writing the label; *Alcon*, creamy white. Many of the spikes had simply numbers to them, so that it was impossible to say what they were. There were four exhibits for amateurs only, and in only one of them, the first prize for eighteen, were the varieties named. The stand consisted of *Mabel*, *Grand Rouge*, *Rossini*, *Marquis of Lothian*, *Princess Maude* (Kelway), *Prince Henry* (Kelway), *Tamerlane*, *Murillo*, *Nercede*, *Crépuscule*, *Colbert*, *Démosthène*, *Giganteus*, *Opale*, *Pasquin*, *Pactole*, *Ordine*, and *Adolphe Brongniart*. I think the careless way in which flowers are so often staged nowadays is much to be reprehended. It must be remembered that they are exhibited for the benefit of others as well as of the exhibitor, and if they are (what I believe they are) in most cases seedlings, then I think that ought to be stated.

It will thus be seen that my contention is true, and I am very much afraid that owing to the lateness of the season a vast number of spikes will never be opened at all. Such are the vicissitudes to which we are exposed in our climate.

AT THE AQUARIUM.

Here the exhibits were fewer than at the Palace, but the prizes were peculiar also. They do not invite the amateur, for the only prize is for a collection of *Gladioli* spikes, no number indicated, and hence the owner of a great number has an advantage which eclipses the amateur, however good his flowers may be. It is hardly to be supposed that an amateur would venture to enter, and only one did, and was rewarded

for his pluck; but when placed with thirty-six alongside of 150, of course he has to sing very modestly his praises. He had some good flowers, but the interest centred in Mr. Burrell's splendid group. Nothing could be finer than this display. I have already commented on the size and excellent quality of his flowers, and as the season advances his flowers seem to increase in beauty. As I have already commented on some of his seedlings. I may here notice those which were exhibited here, and which seemed to me of excellent quality. *Mrs. E. B. Lindsell*, a fine flower of great substance, with a well developed spike, somewhat in the shape of *Orphée*, but larger and brighter in colour. This was awarded a first-class certificate. *Cygné*, a very lovely flower, of creamy white with a yellowish spot in the centre, most chaste and beautiful. *Laretta*, a flower somewhat in the style of *Mabel*. *Asphodel*, another of the fine white flowers which Mr. Burrell has been successful in raising. It is somewhat in the style of *Ondine*, but larger. *Phyllis*—this is a most exquisite and novel flower, ground colour a creamy or lemon white, with a lemon-coloured spot in the centre, which shades off into the most delicate pale feathering, totally unlike any flower that I know. Amongst the named flowers *Abricoté* was much noticed for its clear bright apricot colour, with heavy marking or shading. One is grieved to think that even this chance of seeing some of Mr. Burrell's beauties is at an end, if, as we hear, the Aquarium is to be pulled down.—D., Deal.

GRAPES SCALDING.

In principle Mr. Young agrees with what I have written on this subject, but he characterises my statement as "fancy" that Black Hamburgs, and I may include all other varieties of Grapes, will scald as badly as *Lady Downe's*. It is no fancy on my part, but a fact that I have proved repeatedly. I showed the conditions under which scalding was almost certain to take place, and the precautions necessary were given to enable those for whom the article was written to guard against evils that might destroy their Grapes, and the main, or chief, cause be overlooked. I am justified in believing that Mr. Young "fancies" that it is next to impossible to scald the berries of Black Hamburg and other early and midseason varieties, or that he denies what I state as a fact from an insufficiency of experience. After the bold assertion that it is "fancy" to state that Black Hamburgs will scald, he evidently has grave doubts on the subject, for he places a limit to the statement he makes. If they scald up to midsummer it is the result of bad management, and yet he takes "ordinary" precautions to ward off this evil in the case of the late Grapes under his charge. If they scalded what would it be but the result of bad management? All have not houses of modern construction with ventilators at the top that can be left open without great risk of some bunches being spoiled by rain, or that will open from end to end. Many old structures have one or more lights secured at each end, and no means of opening them. It was to structures of this nature that my remarks were mainly directed, and the precautions pointed out are absolutely necessary to prevent the berries of Black Hamburgs, *Foster's Seedling*, or any others being injured.

It is an easy method of procedure to leave the ventilators open at the top and base all night to guard against scalding. Such action may be tolerated when the cost of production and the value of the crops are not placed side by side. It is the reverse of economy to leave the house open and maintain the desired temperature by the aid of fire heat. Expenses of this nature are not warranted at the present price of Grapes, and if they are to pay for growing, the cost of production must be kept down, and no more fire heat used than is really necessary. I quite agree with what your correspondent says about keeping heat in the pipes.

There is one other point that I cannot allow to pass. Mr. Young says, "to prevent the berries of *Lady Downe's* scalding, no moisture must be allowed to settle on them." A difficult task, but this will do no harm providing it is not condensed in such quantity as to run down the berries and injure the bloom. How do those cultivators manage to keep their Grapes from scalding who employ the syringe to the foliage twice daily until the Grapes commence colouring? I do not believe in such a practice, because it is liable to injure the bloom, but nevertheless it is practised by more than one large grower for market, and yet their Grapes do not scald, nor are more liable to scald from this cause than those who strictly avoid such methods of culture. Mr. Young may "fancy" that there is a difference between moisture falling on the berries from this source and the moisture the berries naturally condense if the temperature falls too low. In dealing with the latter I can say that moisture condensed on the berries does no harm if it is gradually evaporated, as the temperature of the house rises and means of escape for it are provided.

It is easy to contradict a statement but not so easy to prove that it is wrong, and if Mr. Young "fancies" that Black Hamburgs will not scald, the obligation falls upon him to substantiate his views by proof.—WM. BARDNEY.

WHEN reading the interesting article on this subject by Mr. Bardney, I arrived at the same conclusion as Mr. Young—viz., that his fancy had carried him too far. But as this was so unlike Mr. Bardney's practical

writing, I concluded he would oblige us by an explanation. I now see Mr. Simpson comes forward to endorse Mr. Bardney's remarks. Perhaps it is possible to scald Black Hamburgs, but it would require gross carelessness to accomplish such a feat. This is not so with Lady Downe's. I do not remember entirely escaping scalding with this variety for the last nine years. In some seasons only a few berries were touched, but sometimes I have seen them scalded so as to spoil the appearance of the bunches. The past season we have escaped very well, but not entirely scatheless; but I have not seen an instance of Black Hamburg scalding. I have ample proof that both varieties grown in the same house will not scald as suggested by Mr. Bardney's remarks. We have one Vine of Lady Downe's in an early house; I mean a house that ripens its crop in May. It is planted principally with Hamburgs but they never scald, while the former does so regularly, though not to a great extent; still the fact remains. Another house ripening in June has also one Vine of Lady Downe's, but I never saw a berry of Black Hamburgs scalded, while Lady Downe's scalds more or less every season.

Mr. Simpson considers Black Hamburgs grown with very little fire heat are just as liable to scald as any other Grape. This I cannot agree with, and will give a case in point. I am well acquainted with a range of vineries that used to be managed as succession houses, the first crops ripening in May and the last in September. Two were planted mainly with Black Hamburgs, one with Muscats, and the other with Lady Downe's and Black Alicante principally. This garden having changed hands through death in the family, and the present owner having little or no taste for gardening will scarcely allow any fuel for the heating of this range, so the Grapes are now grown almost without heat, none being used till the crops were nearly finished off, so I think I can fairly claim to have a case where little fire heat is used. The four houses all started naturally, and have all finished excellent crops of medium sized bunches. The Muscats are not very well coloured perhaps, but this is the case where fire heat has been employed. Not a Black Hamburg berry has scalded, but I see the Lady Downe's have scalded in several parts of the house. Now, this range has been treated exactly alike, and I think it proves conclusively that there is no comparison between the two varieties as regards scalding. I was very pleased to read Mr. Young's ideas on "fixed temperatures." This is one of the old gardening fads that are not yet obsolete. I am quite convinced Grapes can be and are grown as perfect by Mr. Young's method as by the fixed temperatures insisted upon by some head gardeners. If the truth could be arrived at, these "fixed temperatures" are the cause of far more evils than can fairly be attributed to a rise or fall of a few degrees.—JAMES B. RIDING.

NEW DAHLIAS.

A LARGE number of seedlings were staged at the Crystal Palace Show, especially of the Decorative or Cactus, Pompon, and single types. The seedling show varieties appeared to lack development, as if more time were required to manifest their characters. But one first-class certificate was awarded in the Show section, that for a charming and distinct Fancy named Matthew Campbell, exhibited by Messrs. Keynes, Williams & Co. of Salisbury, the ground colour bright buff shaded with apricot and striped with crimson; fine petal and outline; an excellent addition to the Fancy varieties. A Show variety named William Jackson, shaded crimson, with bright purple edge, appeared too much like other varieties in cultivation. Of new Show varieties, Mr. C. Turner had Glowworm, bright scarlet, and somewhat reflexed, like W. H. Williams; Mary Anderson, very like Mr. Gladstone; and Corsair, buff shaded with gold, the reverse pale purple. Mr. G. Harris, of Orpington, had a few also, but not sufficiently developed to judge of their worth.

Of new Pompon varieties some charming flowers were staged. Messrs. Keynes, Williams & Co., received certificates for the following flowers—Little Ethel, white, slightly tipped with dark purple, good petal and outline, medium sized, very distinct and pretty; Fairy Tales, delicate primrose, fine petal and shape, very soft and pleasing; Whisper, bright yellow deepening to gold at the base, shell-like petals, and perfect outline; and Eden, deep bright shaded crimson, a small, compact, and admirably formed flower. Others of this type from the same firm were—Little Darkie, bright maroon, small, good shape; Red Indian, deep bright red, excellent petal and shape; and Eurydice, blush, tipped with purple, very pleasing. The same award was made to Mr. J. T. West for Pompon Dolly Keith, white, the centre yellow tipped with white; a flower likely to appear in variable character, but a very pleasing addition to the class. Mr. C. Turner had a first-class certificate for Pompon Rubens, maroon crimson shaded with bright crimson; a small and attractive flower of decided merit; Innocence, in the way of Keynes' Little Ethel, and very similar to it; Admiration, and Juliette, yellow tipped with orange-red, also came from Slough.

Of the Decorative class Messrs. Keynes & Co. received a first-class certificate for Panthea, a very bright pale reddish cerise flower of the Juarez type. They also had Amphion, yellow flushed with cerise, fine and distinct; and Honoria, pale bright yellow. The same award was made to Mr. J. T. West for Beauty of Brentwood, pale shaded purple, with bright pale purple on the edge; a purple Juarez. Mr. T. S. Ware had William Rayner, yellow, shaded with cerise and tinted with purple; Sydney Hollings, maroon shaded with purple; and Professor Baldwin, a pale orange scarlet Juarez. Messrs. H. Cannell & Sons had several new varieties. A first-class certificate was awarded to Yellow Juarez, pale primrose yellow, good and distinct; Lilian Aberly, yellow, with

margins of white, distinct, but staged in poor character; Sir Trevor Lawrence and Lady Ardilaun were also shown.

New single Dahlias were numerous, and in not a few cases they were simply counterparts of others in cultivation. Mr. T. S. Ware received first-class certificates for R. C. Harvey, yellow, shaded with salmon, and with a red ring round the eye, distinct and of fine form; Florrie Fisher, white ring round the eye and edged with purplish mauve, fine form; and Mr. Ramsbottom, pale shaded cerise, very distinct and pleasing. Kate, orange-maroon, is a bright and attractive flower. Mr. T. W. Girdlestone received first class certificates of merit for The Mikado, having a yellow ring round the eye, then a broad zone of deep scarlet, edged with primrose, distinct and fine, and Daisy, white, broadly edged with mottled rosy pink, pretty and distinct. Messrs. J. Cheal & Son had the same award for Queen Victoria, the florets white with side margins of crimson, and Duchess of Albany, silvery white, pink, and orange-brown, a Fancy Dahlia among the singles, very distinct. The same award was made to Mr. Henry Glasscock for Gertrude, a charming variety having a yellow ring round the eye, then a zone of white and a broad edging of pale rosy purple, shading to silvery white on the margin.—FLORIST.

PEAR-SHAPED APPLES.

ONE of the most curious examples of changes in fruit that has come under our notice is represented in the engraving, fig. 28. It will be seen what appears to be a Pear and an Apple growing from the same stem, or one blossom producing a round and another a Pear-shaped,

FIG. 28.—TWINS.

fruit. The twins are figured with exactitude. Both fruits are Apples alike in colour, texture, and flavour, and several others of the same nature have been produced by the same tree, some of which are before us. The specimens were sent to us by Mr. Spencer King, publisher of the *Suffolk Chronicle*, and were gathered from a seedling tree in the garden of Mr. S. Gower, Fitzroy Street, Ipswich.

Mr. King, in writing to us on the subject, observes:—"The tree bore Apples last year for the first time, but no twin fruits were noticed. They might have been there, but not observed. The tree is a seedling, but what of or how sown nobody knows. There is no other tree of any kind on the ground. Mr. Robert Garrod, a well known fruit grower, and brother-in-law of the raiser of the tree, says that there were this year certainly a score of these twins, as well as many other bunches of round Apples, and that the specimens I sent you were a fair sample as to size. If he can procure a larger specimen of the round kind he will, and I will send it on to you." We were subsequently favoured with other specimens, both round and Pear-shaped, with the following supplementary note:—"I send another, larger, specimen of the seedling Apple. The Pear-shaped ones did not only grow like the specimen I first sent you, but also singly and in couples. In fact, the two kinds

grew 'just anyhow.' The owner fearing to lose the crop gathered them early, and they do not appear to have attained full size."

The fruits have unfortunately been gathered too soon, and have shrivelled in consequence without the flavour being developed. It is evidently an early dessert Apple. Mr. Garrod considers it resembles the "Margeton," some fair specimens of which we shall be glad to see with the object of determining their identity; in the meantime we advise the owner to take care of his sportive seedling, protect the blossoms from frost next spring if necessary, and we shall be glad to know of the nature of the succeeding crop of fruit.

THE MANETTI STOCK.

How strange Mr. Murphy's praise of the Manetti as a stock reads on page 251 of the Journal. Personally, I long since came to the conclusion that except for manufacturing yearly Rose plants upon—particularly for late budding—the Manetti is worse than useless, for if most Roses cannot live without it they will not live with it in many soils, and I even think some good Roses have gone out of cultivation chiefly through it; Olivier Delhomme, for instance, and Marie Baumann hate it.—S. S.

SPORTS.

"Y. B. A. Z." gives some information as to his experience of Merveille de Lyon sporting. It is not at all unusual where a number of this Rose is grown, as is the case here, to see pink flowers growing on plants here and there. More than this, I have seen several times Rose blooms one half white and one half pink. I should say that these blooms are generally a little imperfect. Last summer being very dry, I noticed a great number of the blooms were pink, but I think in all cases the blooms this season have returned to the proper colour—viz., white. My general experience of Merveille de Lyon is, that it is very similar to Lady Mary Fitzwilliam and the new Lady Alice this far, that where we plant twenty-four Merveille de Lyons we shall probably get one or two Baroness Rothschilds, and where we plant a dozen Lady Marys half of them will be Lady Alices early in the season, and the other half will be ditto later on.—D. GILMOUR, JUN.

MANETTIS AT NEWTOWNWARDS.

Mr. Murphy mentions my name in connection with his article on page 251, and seems to be labouring under the impression that if Roses do well on the Manetti the first year, or from the bud in a genial climate, that the Manetti must be the proper stock to grow Roses on. It is notorious that Manetti Roses will make a grand growth and bloom well the first year with the nurseryman. Poor consolation to the buyer, who finds them fail when he gets them. It is notorious, too, that after the first year the growth and the blooms together grow "small by degrees and beautifully less," "until death closes the painful scene." I could go on pitching into the Manetti over several sheets, but I fear the editorial pen might strike some of it out. I will, therefore, content myself with two facts and a prophecy. Fact one—Nearly all the leading amateur prizetakers are dead against Mr. Murphy's stock. Fact two—My experience of the Manetti extends over many years and over many thousands of plants. The Yankees say "Never prophesy unless you know," but in spite of this I believe and prophesy that twenty years from now the Manetti will not be known in the leading nurseries.—D. G.

ROSES IN WINTER.

(Continued from page 243.)

I LIKE Roses on their own roots, but should not think of thus working up a stock of Niphotos for planting. Without doubt it will do better on the seedling Briar and grow with greater luxuriance. Those worked close upon the root are preferred, so planting or potting is impossible without burying the union; deep planting is then avoided, and the consequences that might follow such a practice.

If I grant, for the sake of argument, that plants either on their own roots or suitable stocks become exhausted when planted out earlier than those grown in pots, then I should advise the former system of culture in preference to the latter. I do so because in the end it would be the most economical, and the greater quantity of blooms and their superior quality would more than compensate for recruiting, or even the renewal of the plants and borders. If I were to attempt, which is not necessary, to draw a comparison of the cost of production in each case, the balance would undoubtedly be in favour of planting out. If the strain of forcing plants in pots and the treatment necessary to keep them as healthy as possible did not enfeeble their growth, why do so many growers have two batches and plant them outside alternately? Without entering into details, such practice points unmistakably to the conclusion that has already been arrived at.

If we glance at a batch of plants under pot culture, is the treatment

they must annually receive calculated to keep them in luxuriant health? When they are placed into large pots and established in them, how long would they remain in a satisfactory condition at their roots if the soil was not partially renewed annually? Let the plants alone at their roots, and the soil in a very limited period will not encourage robust growth, without which blooms of the first quality and in such quantity as to render them remunerative cannot be produced. Repot them annually, and healthy strong growth will certainly be insured provided other necessary treatment is right, but it cannot be accomplished satisfactorily without mutilating the roots to a serious extent. As far as I can judge, the treatment that must be accorded to plants in pots is of such a nature as to bring them into an exhausted condition in a third of the time that would be the case with those planted out.

I have proved that Roses planted out will last for at least a dozen years without the renewal of the plants and borders. The evil to be avoided is overfeeding, and more plants fail from this than any other cause. Strong doses of liquid soon poison the border, and the renewal of it and the plants is a certainty within a very limited time.

If exhausted plants are to be recruited, they should not be allowed to decline too far before they are operated upon. If they are neglected until they reach the last stages of their existence, then the rubbish heap is the best place for them, restarting with young plants. With those planted out, when the border needs trenching up and partially or wholly renewing, as the case may be, perhaps the best course is to have strong plants in 9 or 10-inch pots ready to take their place, so that no serious break in the supply of blooms will occur. But the old plants can be restored to health. These should be lifted in June after they have made a fair quantity of firm wood and show signs of resting. As many fibres as possible should be preserved, and the plants potted quickly. If they can be placed in a shady position outside, and well syringed two or three times a day to keep their foliage fresh, they will soon commence root activity. When this takes place they will not be long before they start into growth, by which means they quickly become established. The border in the meantime should be renewed and the plants placed in it again by planting them without breaking the balls. They will continue making weak growth, and must be thoroughly rested during the winter. They must be pruned hard back in January, and if allowed to start slowly it is surprising what strength they will attain within a year from the time they were lifted. To recruit plants in pots that have been forced early, the balls should be reduced to at least two-thirds by carefully working out the old soil from amongst the roots. They should be placed in smaller pots, and afterwards shifted as required. After reducing the balls and repotting, the plants should be plunged in a shady place at first. During the winter prune them closely, leaving only a few inches of the old stems above the soil, and if allowed to come forward in a cold house or frame they will push shoots of the most vigorous description. If the old stumps were not visible at the base, they would within a year have the appearance of robust young plants.—WM. BARDNEY.

PLANTING AND TRANSPLANTING STRAWBERRIES.

ALTHOUGH Strawberries are easily grown, they are very often carelessly cultivated, this entailing a waste of labour as well as of land, and resulting in poor crops and deficient fruit. Some varieties will endure more ill and careless treatment than others, but all are more or less impaired by improper treatment. Many growers of Strawberries make no provision whatever to protect and select the runners, nor even to treat those they obtain with the care that is necessary for producing fine plants and fruit. A very usual custom, even in some otherwise well-regulated gardens, also in market gardens, is to gather the fruit and tread down the runners, at the same time spoiling most of them, and apparently caring for none. When the runners are lifted the work is often done roughly, the young plants thrown into a basket, then often allowed to stand in the sun for a considerable time drying the roots. This check at the outset is fatal to the production of a satisfactory crop of fruit. Sometimes basketfuls of runners are placed in a shed for several days, and more mischief is done in dressing them by cutting off many leaves. No good leaf should be removed from a Strawberry plant. After all this manipulation and mutilation, the plants are either laid in rows as thickly as they can be packed, or planted permanently with a common dibber, the roots in both cases being pressed tightly together. This entirely prevents free growth, and substantial fruitful plants cannot result from the process. A plantation of Strawberries thus carelessly made never yields a fair or even half a crop.

Strawberry beds are too often allowed to become a mass of runners and weeds, and to remain so until the autumn, if not till the following spring. The labour in cleaning the plantation is then considerable, and the ground is filled with seeds for raising more weeds to choke the Strawberry plants. All this is preventable by the timely application of a hoe, and at less than a twentieth part of the expense incurred through dilatory action, while a gain of 100 per cent. follows correct treatment. Weeds in the soil and

weed-growers are great stimulants towards depression. The foregoing is not an overdrawn picture, but has been witnessed in many places; it is, indeed, the rule rather than the exception in some districts, both in private and market gardens, and is ruinous. Let anyone try an experiment between the foregoing and the following plan, and I am certain that he will never revert to the slovenly method again.

Strawberry plants carefully selected from specially prepared plants, and planted with their roots fresh, and placed in the ground in their natural position in well-prepared land after a winter crop, or even after an early summer crop, such as early Peas or Potatoes at the end of July or early in August, make more headway than plants inserted in spring or the autumn previous, and are often far larger by May and June following, and bear a much greater crop of superior fruit than can be had from old, exhausted, weed-choked plantations—indeed thrice the value of fruit can be had by this plan from a given plot of land, and with a far less exhausted soil and freer from weeds, with a tithe of the labour the other system entails.—W. T.

NOTES ON GLOXINIAS.

THESE invaluable summer flowering plants appear to revel in a sunless season, judging from the numerous well grown plants that have been seen at recent exhibitions. In this neighbourhood there are several gardens in which Gloxinias are well grown, and the prizes offered at the late Frome Show brought together a highly meritorious collection, the plants being most vigorous and healthy, and furnished with blooms remarkable for size and variety. The best lot of these plants I have inspected are those in possession of E. R. Trotman, Esq., Frome, and they are highly creditable to his gardener, Mr. Bridgeman. The plants are now flowering for the third time, and were obtained from seed supplied by Messrs. Cannell. They are grown in a large lofty vinery, and are not subject to much heat at any time. They occupy a position round the front on a slate staging, and from the high elevation of the roof abundance of light is provided. On inquiry as to the treatment they received in the manner of feeding and soil, I was told various artificials have been adopted, but diluted stable drainings appeared the most stimulating. Sulphate of ammonia is used by some, and it has been experimented with here, but was found to injuriously affect the leaves, causing them to assume a rusty appearance. The soil was composed of peat, loam, and sand in equal parts; but it may be well to mention the fact of the loam being of so light a character and of very good quality, leaf mould, which is of considerable importance generally, is dispensed with. They occupy pots 7 inches in diameter, and forty blooms on a plant are sometimes expanded at one time, and on many plants thirty flowers could be counted at the time I saw them. The strain is a good one, the colours being varied and the blooms remarkably large. To maintain a good number of the very best a packet of seed is sown each season. When the plants attain a flowering size the best are selected and inferior ones thrown away, an excellent plan when high quality is desired. Good strains of Gloxinias may be obtained now from most seedsmen, who cannot long afford to keep inferior stocks. February and June are very good dates for sowing; the seeds and plants from either, when carefully attended to, can be flowered the same season.—W. S., Frome.

NOTES FROM A HERTS GARDEN—REFLECTIONS.

SOIL a stiff loam, subsoil clay. Formation peculiar, baffling description; suffice that in this particular spot chalk exists at 80 feet beneath the surface, which can but remotely affect the present vegetation. The original soil, as seen in adjoining land under permanent pasture, is 12 to 15 inches in depth of workable material with a clay subsoil more or less stony and impervious to water. Out of such land an area of about 4 acres had some time been selected as the site of a kitchen garden. Its exposure is south, inclining somewhat sharply in that direction, and less so westward. North the ground rises to a height of about 65 feet, clothed in park-like order with majestic Oaks. The highest point of the ridge is 396 feet above sea level, consequently the part used as a kitchen garden has an elevation of about 330 feet at the upper part, and 300 at the bottom. About 2½ acres are enclosed by walls 10 feet above ground, but the south and north walls are double the length of the others. The sun is at right angles with the north and south walls at about eleven o'clock, therefore passes the assumed meridian at eleven o'clock instead of twelve o'clock. Some forty years ago the garden was drained, and the drains are still thoroughly efficient. Some of the clay was burnt to hard particles, and these form a layer mixed with clayey stuff about 6 inches thick over the undisturbed subsoil. The least burnt or crumbly portion was mixed with the top 18 inches of the soil. Chalk has been applied to portions, probably the Strawberry quarters, and ashes to other parts, to improve the working of the soil. Lime does not appear to have been used, but it is present in the soil through occasional dressings of gas lime as obnoxious or destructive of slugs.

Altogether there is a depth of 2 feet to 2 feet 6 inches of strong loam which does not appear to have been stirred deeper than a foot within a generation.

Outside the walls are the customary slips, and there are walks of 7 feet 6 inches in width, both inside and outside, so as to admit of a horse and cart for manuring, &c., and a liquid manure cart also when deemed expedient. The inside is divided into four quarters by cross walks equally wide, and along their sides are borders planted with fruit trees of various kinds, both on dwarfing and on free stocks, remnants in most instances of renovation, though some have collapsed and been replaced. The walls, I may further premise, are utilised for fruit-growing, both under glass structures heated and unheated, and exposed, of some or all of which I shall have, from time to time, some observation to make or experience to record; and the first is that the land generally in the locality is, as evidenced by the herbage and the cattle that browse thereon, and as described by Mr. W. F. Emptage at the recent Fruit Conference at St. Albans, "some of the finest land in the whole world." It grows by the aid of London "muck" in a dry season one and a half to two loads of prime hay per acre, and in a wet season two to two and a half loads per acre (1887 and 1888 being representative of a dry and wet season respectively). I shall now remark that, considering the present marketable value of beef, mutton, and hay through proximity to the metropolis, their production is the best possible use to which such land can be put in the present state of agriculture. To convert land suitable for permanent pasture or meadow (supplying the home markets directly with the primest hay, beef, and mutton at remunerative prices and upholding of the national prestige) into vegetable and fruit gardens is a misapplication of natural resources. Is it not absurd to seek to apportion all the best of pasture and meadow land into allotments and fruit farms? Surely there are gardens enough to meet every demand, so far as our climate admits, by the home grower of fruit and vegetables if cultivated up to their capability of production. What of the orchards that present a spectacle of stunted, weather beaten, cankered moss and lichen-covered specimens, lovely in blossom and picturesque, with crab-like fruit in autumn, a picture none but an artist would call sublime?

An orchard of suitable trees, certain of cropping and of bringing remunerative prices in the market, would be the means of helping the farmer in a season like the present, only it seems nobody this year has a paying crop of any description of fruit; either the trees are fruitless or spoiled by the wet. That is just where the "rub" comes in. The crops of fruit in this country are not certain on account of spring frosts, blight, or drought; or if they hold on despite of wind and weather something is sure to happen to prevent the cultivator realising anything like the profits paraded before the world. But when failure comes we are told "We have been practising on wrong lines—planting standards on grass when we ought to have planted half-standards and cultivated the ground between." But when this plan fails we were wrong again, and "ought to have gone in for bushes, pyramids, espaliers or cordons," and instead of growing many have been content with few sorts suited to the locality, certain croppers, and excellent imported produce. Just the things are those everybody wants to get hold of—something that can be grown profitably. Fruit Conferences tell of want of fruit and vegetable supplies; the thing that puzzles all is finding the goose that has ceased laying the golden eggs. At the St. Albans Fruit Conference I notice by the newspapers that Mr. Emptage characterises trenching as damming fruit culture in that district, and at the Crystal Palace Conference Mr. Bunyard looks upon deep cultivation as the salvation of the fruit industry. Which is right? Could not the Royal Horticultural Society solve the problem? Why not devote an acre, or 5 acres for that matter, to the cultivation of fruit for profit, an account being kept of the first and after cost, and have it free of access to all? It would only serve its purpose for a particular locality. Then why not have fruit gardens in different parts of the country in connection with the parent Society as a guarantee of management and result? Experimental gardens could not fail to give a great incentive to fruit culture.

The influence of an exhibition of an acre of fruit trees on the old lines—i.e., orchard—another on the cultivated system as standards or half-standards, with under and between crops, and an acre of bush, pyramid, espalier, or cordon trees, would practically demonstrate the systems, and do more to guide others than all the conferences that ever took or will take place. What is wanted is not talk but practice. Definite information in respect of the capabilities of the soil, the most desirable crops to grow, and the most approved method of cultivation, something tangible whereby to arrive at a solution of the problem, which puzzles everybody just now (and ever did by what I can glean of man since Adam), what to put in the market that will return a fair per-centage on the capital invested, industry employed, and enterprise

with energy displayed. Conferences only mystify would-be cultivators. Well may the public look askance at savants not agreed, and when doctors differ who will step into the breach? Here is a chance for the Royal Horticultural Society to regain its prestige and earn the everlasting gratitude of the country.

I have been led into this discussion by reading the reports of the Fruit Conference in the newspapers. To find a statesman cudgelling farmers and labourers—horn tillers of the soil—into seeing something in fruit and vegetable growing that will assist them to stem the current of depression is most suggestive—of what? Well, what you like. I know it is only by the efforts of individuals that good can come, and so far as I can see it never came but in one way—viz., in cultivating the soil so as to produce a maximum of useful products with as little outlay as is practicable.—UTILITARIAN.

SEASONABLE NOTES. DISBUDDING.

CULTIVATORS of plants for the production of large blooms will now be busy "taking" the buds as fast as they form. This phase of the culture of Chrysanthemums for the purpose named is perhaps the most important of the details required in producing the best results. No person can go far wrong if he retains all the flower buds now showing, removing the growth shoots as soon as they can be handled, because to allow the growths to extend, taking out the bud instead, then waiting for the last bud which will form at the extreme point of the shoot, would not result in success, if I except perhaps one or two cases of incurved varieties—notably the Queen family in the extreme south of England. To have good blooms of the Japanese varieties the buds as showing now must be retained. The best time of the day to remove the growths is early in the morning, when the dew is on the leaves and shoots, rendering the growth more succulent and easier to take off than it is in the middle of the day, when the leaves are dry and the shoots soft, as they are with the sun shining. There is a danger at that time to injure the flower buds. The best way to proceed is to hold the stem near the top securely in the left hand, and with the right give the lateral shoots which spring from just below the bud a sharp bend in a downward direction, when they easily snap off. If a suspicion exists that the bud has been damaged one growth should be allowed to remain near the point of the branch for a few days, as the bud, if at all disfigured, cannot possibly develop into a perfect bloom. If it is thought best to remove the bud and allow the shoot to grow it will produce a bloom even if a small one. By the removal of all lateral growths at each node which burst out during the temporary check given to the plant by the formation of a flower bud the whole energy of the plant is concentrated to the flower bud at the point of each branch. Three blooms to each plant is the orthodox number allowed. Much better it is to have this number of good quality than to attempt more and have them small. When the exhibition table is reached this will be found to be good advice.

SECURING THE BRANCHES.

The branches as they extend should be securely tied to their supports. Neglect of this detail at this season is often attended with serious results, such as the breaking of the shoots just below the buds, which are at that particular point very soft, and in most varieties they are liable to bend; added to this the weight of water lodging among the leaves during showery weather often cause the points to snap off. Birds seem to be very fond of alighting on these points, which if at all bent by their own weight are almost sure then to break. The shoots grow so fast at this stage that almost daily attention is necessary to keep the ligatures in proper order. If the stakes are rough through the bark being upon them or knotty the ties do not slip up as growth proceeds, consequently the shoots buckle and in time snap off. This often happens with the good or scarce varieties. Generally the plants this year are not so tall as in some past seasons, owing possibly to the sunless cold spring. The plants in consequence did not make that free growth from the time they were rooted as is their wont under more favourable weather.

WOOD RIPENING.

The wet sunless summer has been all against ripening the wood as growth progressed. This must have been much felt by those persons residing in the northern counties of England or in low-lying flat districts. Those on breezy hills are certainly favoured this year in this respect. I should not be surprised to see many large loose blooms this season from unripened plants. Soft sappy stems cannot produce flowers of the same depth and firmness as plants do which are grown throughout the season under more favourable conditions. The stems require solidifying as growth proceeds. No artificial treatment can make up for an

insufficiency of solar rays. Particularly is this felt in the incurved section. To make the most of favourable weather the branches should be trained as thinly as possible for gaining the desired end—properly ripened wood.

WATERING AND STIMULANTS.

Watering the plants has been an anxious operation this season. During such showery weather as that experienced, applying water to the roots when required has been difficult to perform. For days together the plants received more rain than was good for them, causing in some instances a loss of the lower foliage. After a spell of wet weather it is wise to allow the plants to approach dryness somewhat before applying water to the roots as a counteraction to the soddened state of the soil in the pots. Care should be exercised in the use of stimulants in such weather as has prevailed for fear of rendering the branches gross in character. Until the buds are freely swelling it will not be wise to give the plants much aid beyond a little soot water for keeping the foliage of a good colour. After the buds are freely swelling stimulants may be given, varying the kind as often as circumstances will allow. Liquid manure made from sheep or cow manure is efficacious. The soaking from the manure heap, too, is good. The various kinds of artificial manures recommended are no doubt all good if the directions accompanying each are faithfully carried out, but where such is not the case it is useless to blame the manures.

INSECT ENEMIES.

Insect pests are numerous this season. The palm in this direction must be given to the earwigs. I never saw them so numerous, it not being an uncommon occurrence to find thirty and forty inside of a 2½-inch pot containing a small portion of moss, this being a good trap for them. Stems of Broad Beans cut into lengths and placed among the leaves are also useful. The chief damage earwigs do to the plants is injuring the buds while in a young state; if these are disfigured then it is useless to expect perfect blooms, as any injury done to the young bud is certain to develop later on. Caterpillars upon the leaves are also troublesome this season. Nothing but searching at night and handpicking will clear the plants of these.

MILDEW.

Mildew is now very conspicuous on the leaves of some varieties. Frequent dustings with sulphur—that of a brown colour is best—on the affected parts will keep this in check if taken in time, otherwise more severe measures must be had resort to, such as syringing the plants thoroughly with a liquid preparation made in the following manner:—Place 2 lbs. of sulphur and 2 lbs. of lime, which has not been slaked, in ten quarts of water, and boil for twenty minutes. For syringing on the plants use two wineglassfuls of the mixture to four gallons of clean cold water. A thorough drenching of the foliage should be given, using the jet, which causes a single stream to be poured on the plants. By placing the forefinger of the left hand over the orifice the liquid can be directed at will during the operation.

DECORATIVE PLANTS.

Bush plants of single, Pompon, and Anemone Pompon varieties grown for the use of the conservatory to flower in masses will need strict attention now for keeping their foliage in good condition, this very much enhancing their appearance as decorative plants. It often happens that these plants are grown in small pots for the sake of convenience as to space. Capital objects may be had in 7-inch and 8-inch pots if the necessary attention be given the plants. The principal part to be considered is timely attention in applying water to the roots. Alternate applications of liquid manure may be given to the plants now. If larger blooms be wished for, only the buds now forming at the points of the branches should be retained, removing the others. A few points on each plant will suffice to secure larger blooms of these sections, while the remaining branches may be allowed to flower profusely. *Sœur Melanie* is one of the best sorts to grow for a profusion of pure white flowers. As an edging to a group in the conservatory or elsewhere this variety is capital, as it generally carries more foliage than most sorts.—E. MOLYNEUX.

THE ROMANCE OF SEED-SOWING.

(Concluded from page 217.)

BESIDES these four methods of dispersion, previously referred to, there is one other occurring in a few cases and deserving of notice. I refer to movements of the plant itself—i.e., of some portion of it.

Dandelion, after lying horizontally among the grass while ripening its seed, rises to an erect posture, thus enabling the wind to act on the parachute-like pappus surmounting the fruit. On the other hand, many plants by their movements provide not for dispersion of seeds by wind, but for burial of them in the soil. The small white Subterranean Clover (*Trifolium subterraneum*) of our commons and downs is a good example. Here, instead of the large number of florets seen in a head of purple Clover and others, only about three of the bunch become well-developed florets with pods; the rest remain abortive in a sense—i.e., they are developed into a number of short fibres, each having four or five divisions like the fingers of a hand, but of course very minute.

These palmate fibres together form a small green knob in the centre of the flower head. The whole plant lies close to the ground, except that at blossoming time the three florets stand erect to secure fertilisation by the bees. This accomplished the stem lengthens and turns

downwards, the palmate fibres are developed, and, being central, on touching the earth they bury themselves with a screwing sort of movement, thus working a hole into which the three pods, which have by this time bent downwards, are drawn and effectually buried. Under the plant safely stores away its pods full of seeds, which ripen underground during autumn and grow up in spring. The plant, growing only on ground quite closely cropped by animals, in this way secures reproduction by burying the pods safely out of harm's way. It sacrifices some of its flowers in order to make natural gimlets, which dig a grave for the three seed-bearing ones!

Many other plants, possessing the usual aerial pods, have also subterranean ones, usually shorter and with fewer seeds, the smaller number being an advantage, as they the more easily flourish when trying to germinate close to one another, while in the aerial pods a larger number of seeds evidently secures a better chance in the scattering process. Of these plants we find examples in some species of Vetch, Vetchling, and Cress. In American Earth Nut (*Arachis hypogea*), the "nut" so called—in reality a pod—is buried while still unripe, and later on underground develops its two seeds. If the burial for any reason be not made, the pod withers and no seeds are produced.

Some cases exist in which movement of the seed itself, after it has left its capsule, either scatters or buries it. The seed of Wood Sorrel (*Oxalis*) ruptures its testa or coat, expelling the body of the seed with violence. The Stork's-bills, belonging to the Geranium order, possess seeds which develop a hairy, twisted "awn," which, under given conditions, principally of moisture, unrolls and pushes the seed down into the ground, the awn itself being kept fixed by surrounding herbage. *Stipa pennata*, a pretty European Grass, has seeds with a corkscrew rod and long feather springing from their apex; the whole arrangement is over a foot long, and in moist weather the unrolling of the rod acts as in the Stork's-bill seeds, the feather probably serving the purpose of carrying the seed first of all to its resting place. The elaters, contractile filaments forming part of the spores of the Horsetails, act in somewhat similar manner by fixing the spores to the earth, and in some water weeds the spores are furnished with vibratile cilia or fine hairs, enabling them to move in the water spontaneously, and so disseminate themselves.

We have now seen the various agents and contrivances by which weeds are placed in favourable situations for growth, and we cannot fail to be struck with the wonderful adaptation and ingenuity of many of them. That the wings, or the hooks, as the case may be, are not mere accidents or ornaments, as some would have us imagine, but exist for the purposes named, is, I think, fairly established by looking at the kinds of plants on which they are found, and considering their stature. Sir John Lubbock, in a most interesting paper in the "Fortnightly" for April, 1881, gives us the two following statements (I quote them in outline only):—

I.—"Roughly speaking, there are some thirty genera, belonging to twenty-one different orders, having seeds or fruits with wings. They are all trees or climbing shrubs, not one is a low herb. That is, they all occur in situations where the wind has free access to them. If the wings were merely accidental, why do we not find them on low-growing shrubs and plants?"

II.—"There are about thirty English species where dispersion is effected by hooks, causing the fruits or seeds to adhere to the coats of animals. If these hooks were simply ornamental, or present by accident, why do we never see one such hooked fruit on a water plant or a tall tree? What is the actual fact? Out of these thirty not one is aquatic, not one is over 4 feet high, not one grows at a level below that at which seeds would be likely to get entangled in the fur of animals having reference to the usual size of British Mammals."

Thus approached, the "keys" of Ash and Sycamore circling through the air, the silvery down of Thistle and Dandelion, the rich deep crimsons and purples of our woodland fruits all have meanings for us; we behold in all of them additional evidences of the great truth of natural selection, by means of which, through countless ages, the Great Designer has slowly and certainly evolved the myriad forms and colours of fruits and seeds that call for study and attention; and we look with wonder and delight on them all, as, with perfect adaptation of construction to purpose, fruit and seed are sent forth far and wide on their beautiful mission of regeneration and abounding life.—H. W. S. WORSLEY BENISON, F.L.S. (in the *Journal of Microscopy*).

GOOD PEACHES AND NECTARINES FOR WALLS.

THERE are several of the late big Peaches of excellent quality when grown under glass, but without some assistance to bring them to maturity I consider it quite useless attempting to grow them. It is very true in favourable seasons a healthy tree, if growing in a good position, may ripen its fruit fairly, and the grower thus have an opportunity of placing on the table a passable dish of Peaches late in the season. But this is, according to my experience, a very rare occurrence. The fruit generally becomes woolly, bitter, and decays at the stone. I have tried to assist their ripening on several occasions by gathering the fruits and placing them in heat, but have never succeeded satisfactorily, and they after all have been only fit for making tarts of. Mr. Gladstone, Lady Palmerston, Walburton Admirable, Princess of Wales, and Salwey are some which never ripen well here, and we intend to replace them with some others that ripen somewhat earlier in the season. Our best, both as regards cropping regularly and quality, are Alexander

Noblesse, Old Noblesse, Bellegarde, Stirling Castle, Grosse Mignonne, Crimson Galande, Barrington, Early York, and Hale's Early; and all of these with the exception of Crimson Galande I know are excellent for forcing. It may be said I have left out the best of all Peaches, viz., Royal George. For indoors we have none to surpass it for cropping and quality, while outside it has so terribly suffered from mildew with us, that I doubt whether or not it should be included in an outside collection. À Bec, Condor, Dymond, and Belle Baucé I have added to my list, and I fully expect in the first three to have something good. Dymond is now bearing a few fruits, and I like its appearance immensely. For very early use either Waterloo or Alexander should have a place, both of which ripen fully three weeks before Hale's Early but the latter I prefer for quality.

With regard to Nectarines, Lord Napier is the first to ripen, and give great satisfaction for size, quality, and cropping. Humboldt seldom fails annually cropping heavily, and is grand for colour and flavour, in fact I consider it one of the best if not the best Nectarine grown. Elruge is a certain cropper both in and out doors, and is well known as one of the best, while Pineapple and Pitmaston Orange are all that could possibly be desired. Albert Victor and Victoria do not ripen satisfactorily here, and the fruit splits when quite green and hard.—H. MARKHAM *Mereworth Castle, Maidstone*.

CHISWICK GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.—We understand that the members of this Association have decided to hold a soirée at the Vestry Hall, Chiswick, on October 17th, the proceeds from which are to be devoted to the Gardeners' Orphan Fund, and is hoped that the efforts of the Committee will meet with the support of the gardening community in Chiswick and the surrounding districts. Tickets for the soirée, 1s. each, may be obtained on application to the Secretary of the Association, Mr. J. Barry.

— FLEMISH BEAUTY PEAR.—Mr. J. Hunter sends us a fruit of this variety grown under glass at Lambton Castle. It is 11½ inches in circumference and 4 inches long exclusive of the stalk; the skin is transparent and glossy, streaked and flushed with red, the specimen as combining size with colour being one of the most handsome we have seen.

— A LARGE bed of Madame Desgrange Chrysanthemum is one of the features of HAMPTON COURT GARDENS in October. This year the plants are a little irregular, and several of them appear to be producing growths differing from the original, but flowers on these are not expanded. A bed of G. Wermig is a sheet of soft yellow, this sport invariably flowering earlier than its white prototype. Mrs. H. Hawkins, the new golden sport from G. Wermig, is an acquisition of the season, and likely to be extensively grown in pots and borders.

— WE have received the schedule of the LEDBURY AUTUMN FRUIT SHOW, which is to be held on October 25th. Prizes are offered for collections of dessert and culinary Apples, also for single dishes of approved specified varieties of Apples and Pears, with a guinea prize for the heaviest Apple. Cider and perry fruits are also provided for, and there are two classes each for Grapes and Tomatoes. The competition, we presume, is open to all, though this does not appear to be stated in the schedule. Mr. Jesse Garwood, Ledbury, is the Honorary Secretary.

— APPLE GRAND SULTAN.—A few trees of this variety will be found useful where early dessert Apples are in demand. Worked on the Paradise stock, and grown either as upright cordons or bushes, they bear abundantly. The fruits ripen with us about the end of August, and for early Apples are well flavoured if eaten as soon as ripe; but they soon become "sleepy" and decay round the core, so that for private use two or three trees are sufficient. Their attractive appearance and pleasant scent would secure them a ready sale in the market.—J. H. W.

— A GOOD CATCH OF EARWIGS.—Mr. H. Osman writes:—"Having found something was eating the fruit on a Peach and Nectarine tree, I inserted about two dozen earwig traps—Broad Bean stalks, &c. I found yesterday on blowing the contents into boiling water I had caught a very great number. Therefore, to satisfy my curiosity, I counted them, and found 513, then seventy-seven in one trap,

which makes a total of 590 from the two trees. This number seems incredible, nevertheless it is a fact. Are any other readers troubled with such numbers? "

— THE CZAR PLUM.—This is a good culinary Plum, and a sure and heavy cropper. It ripens with us early in August, close after Early Rivers. We grow it as single cordons on a wall with an east aspect, and it never fails to bear a heavy crop of fruit. For market purposes it will be found as remunerative as Victoria, and would be cleared off three or four weeks before that variety was ready.—J. H. W.

— GARDENING APPOINTMENT.—Mr. R. Mitchell, for two years foreman at Gifford House Gardens, Rochampton, has been appointed gardener to W. Cunard, Esq., Orleans House and Lebanon Gardens, Twickenham. Mr. John Thomson, for the past six years head gardener at Dennis Hall, near Stourbridge, Worcestershire, has been appointed gardener to R. W. Wilbraham, Esq., Delamere House, Northwich, Cheshire.

— MR. G. CUMMINS, in sending a few very fine flowers of ANNUAL CHRYSANTHEMUMS, writes:—"These have proved to be valuable wet weather plants. They have not only grown vigorously, but have bloomed profusely all the season. I do not remember seeing a finer lot than I witnessed the other day at Putteridge Park, Luton, where these plants are used extensively in beds and borders. I enclose a few blooms to show the quality as grown there."

— MELON THE BLENHEIM ORANGE.—W. Iggulden writes: "I can fully endorse all that Mr. A. Young says in favour of this excellent Melon, and am glad to learn he succeeds so well with it. Mr. Austin used to grow it extensively at Ashton Court, and I have seen numerous very handsome fruit, both early and late in the season, there produced. This Melon, unlike many other varieties I could name, still retains all its original good qualities, and if there is any fault to be found it is its rather too vigorous habit of the growth at the outset. We cannot set a heavy crop on the first laterals, but the plants go on growing and setting fruit at short intervals throughout the season. If not eaten for a few days after the fruits are cut from the plants the quality is exceptionally good, and instances have come under my notice this season where Blenheim Orange in good condition has beaten the best green flesh varieties in competition with it."

— A COMPANION FOR BLENHEIM ORANGE.—The same cultivator says: "This will be found in Hero of Lockinge, another variety that has not lost its good reputation in any way. With us it is fairly vigorous, very free setting, and the fruits are of good form, very handsomely netted, and bright golden yellow in colour. This again is not fit to eat when first cut from the plant, and ought to be kept till the rind is soft, otherwise only about half the flesh is eatable. Hero of Lockinge and the foregoing are equally well adapted for either house or frame culture, and are the two varieties most extensively grown here."

— CLOVES IN POTS.—"S." writes:—"Anyone who has not grown the old crimson Clove in pots for early flowering would do well to do so, as well grown plants are extremely useful, affording flowers for cutting that from their rich perfume and colour are always welcome. A stock of plants is easily obtained when a few old roots are to hand. Layer at once the current season's growth. When well supplied with roots pot them two in a 5½-inch pot, using moderately rich soil. Stand them in a cold frame until new roots are formed, then an open position out of doors on a bed of coal ashes will suit them for a time; afterwards a cool house will answer for them, where they will flower."

— AN EARLY PEACH.—Peaches have been generally scarce and very late as an outdoor crop, but one variety I have noticed as being particularly good and early this year is the Waterloo. It is an American kind introduced into this country by Mr. Rivers. The tree under notice perfected its crop early in August, which may be considered very early for the dull sunless season experienced. It is planted against a south wall, and was fully three weeks earlier than Hale's Early, occupying a position close beside the first named. Those who contemplate planting any Peaches this autumn for outdoor uses would do well to bear the earliness of the above variety in mind.—W. S., Frome.

— EARLY FROSTS.—The present season has been one of the most variable and cold experienced for many years, and frosts of a slight character have been more frequent than many imagine, at least in this neighbourhood. Probably they have been noticed here through the close proximity of the river Froome and the low lying nature of the surroundings. But from whatever cause there was during August sufficient frost to affect tender vegetables, such as Vegetable Marrows

and Runner Beans. On the mornings of the 9th and 10th of the present month the mercury stood at freezing point, and hoar frost was plainly visible on the ground. But so far no apparent injury is perceptible from the low temperature on vegetation generally.—W. S., Frome.

— NEW MELONS.—A correspondent writes: "It is so rare now that Melons are certificated, only four varieties we believe having received such honours during the last three years (this showing a very wise discretion on the part of censors), that any new aspirant so marked for public approval is quite worthy of special mention. Mr. William Palmer's Thames Ditton Hero, honoured last week, had been grown in a frame, for which system of culture this variety is especially valuable. It is a very free bearer and setter, having fruiting blooms at every lateral, often a pair together. The variety is of good flavour and of a suitable size for table. It is the result of a cross between Scarlet Premier and High Cross Hybrid."

— AT the last of the monthly meetings organised by BELGIAN HORTICULTURISTS AT GHENT the following awards were made:—Certificates of merit to *Cypripedium niveum*, Stonei, and *Harrisianum superbum* from Messrs. Vervae & Co.; *Tricopilia* species from the same firm; *Odontoglossum grande superbum* from M. James Bray; *Dracena norwoodiensi* from M. Desmet-Duvivier; *Maranta inconfira* from M. Alexis Dalliére; and to the following new seedling *Coleuses* from M. Edouard Pynaert—M. Paul Dutrie, Madame C. Van Geert, Mdle. Rosa Rooses, Comte de Grünne, Etoile de Gand, Souvenir de Jersey, and Souvenir de Guernsey. Honourable mention to *Cypripedium Javanico-superbiens* (for novelty), *Lilium auratum superbum* (for floriferousness) from M. Bernard Spae; and *Adiantum Weigandi* (for cultural merit) from M. Liévin Spae.

— THE IRISH EXHIBITION.—Lord Arthur Hill requests the insertion of this paragraph, with a view to aiding the industrious peasantry of Ireland. Though not a gardening subject we willingly comply for such a purpose:—"Lately there has been a great increase in the articles, such as lace, embroidery, underclothing, painting, knitting, wood carving, &c., sent over to the Old Irish Market Place by poor peasants in Ireland. In most cases this work is the senders' sole means of support, and it is most desirable that it should not be returned to them unsold. Visitors to the Irish Exhibition would be giving material help and encouragement to these peasants by going to the Old Irish Market Place, and making some purchases, however small. The inmates of many a humble cottage in Ireland will have cause to be thankful during the coming winter if the work they have sent to the Exhibition is sold."

— THE following is sent to us for publication:—"In view of the imminent REVIVAL OF THE FLORISTS' TULIP, Messrs. Stuart & Mein have just completed the purchase of the famous collection of Mr. David Barber, Stanton-le-Dale. The collection contains several thousand bulbs of the best varieties in existence, many of them never having been offered for sale to the public. Mr. Barber, who has several times won the champion cup and other prizes open to all England, is one of the last of his generation of enthusiastic Tulip growers. He is upwards of seventy-three years of age, and for a period of upwards of forty-three years he has gathered together and grown his favourites. It is satisfactory to record that this famous collection has come to Scotland, and we are sure that nothing will be left unaccomplished that skill and enterprise can do to make the collection equally famous in this country."

— THE following summary of METEOROLOGICAL OBSERVATIONS FOR AUGUST, 1888, is supplied by Mr. Joseph Mallender, Hodsock Priory, Notts:—"Mean temperature of the month, 57.5°. Maximum on the 9th, 81.1°; minimum on the 18th, 38.3°. Maximum in the sun on the 9th, 132.7°; minimum on the grass on the 16th, 33.9°. Mean temperature of the air at 9 A.M., 58.4°. Mean temperature of the soil 1 foot deep, 58.4°. Total duration of sunshine, 133 hours, or 30 per cent. of possible; we had five sunless days. Total rainfall, 2.06 inches. Maximum fall in twenty-four hours on the 28th, 1.16. Rain fell on thirteen days. Average velocity of wind, 8.3 miles per hour; did not exceed 400 miles on any day, and fell short of 100 miles on four days. Approximate averages for August—Mean temperature, 60.2°. Rainfall, 2.52. A cold rather dull month, but not wet until near the end; in fact, if not for the heavy fall on the 28th it would have been a very dry one."

— GROS MAROC GRAPE.—Your correspondent "W." asks, page 246, "Are there not two forms of this Grape in cultivation?" The same

thing has struck me several times lately. We have four Vines of this Grape growing in a Muscat house, three of which are oval-berried, while the other has rounder berries. So far as I am able to judge they are all raised from eyes. Dr. Hogg gives the oval-shaped form as the true type in the "Fruit Manual." As "W." remarks, it is a very handsome Grape, producing fine bunches and berries. With us the smaller bunches are better finished than the larger ones, but its good qualities are decidedly external so far as my experience goes. It is subjected to the necessary amount of fire heat to ripen Muscats in September, but its flavour is never more than third-rate. It does not keep in good condition after November with us. In fact it is held in such little favour here that it will be entirely discarded, for only good flavoured Grapes are appreciated.—JAMES B. RIDING.

— SHANKLIN, ISLE OF WIGHT, HORTICULTURAL SOCIETY.—Mr. C. Orchard writes:—"One of the most successful affairs I have seen to augment the funds of a Society took place at Shanklin last week. It will be remembered that on the day the Show was held it was fearfully wet, and consequently the visitors were deterred coming to the Show and visiting the very beautiful grounds of Rylstone, the seat of Mous. Spartali. On Tuesday, the 11th inst., they were given another opportunity. The Treasurer, H. Gibbs, Esq., and the Committee organised a procession through the town, when many of the characters from the recent carnival at Ryde took part, headed by two bands of music. They paraded the town, and on arriving at Rylston found the grounds, also the dwelling house and the beautiful summer chalet, splendidly illuminated with coloured Chinese lanterns; these, with the coloured fire that was provided amongst the shrubs and in the dells, gave it quite a fairyland appearance. Fifty pounds in sixpences were taken at the gates, and although it is estimated there were quite 3000 persons there, it is satisfactory to know that there was scarcely a flower or a tree damaged."

— THE ENGLISH APPLE AND FRUIT-GROWING COMPANY.—The prospectus of this Company, which has been expected for some time, is now published. The capital proposed to be raised is £50,000 in shares of £1 each. The Directors of the Company are Messrs. C. J. Heald, Brighton; A. F. Barron, Chiswick; J. Cheal, Crawley; J. Roberts, Gunnersbury; with power to add to the number. A contract has been entered into to purchase nearly 300 acres of land in Kent suitable for fruit-growing, the price for which is £7375. £1000 worth of shares appear to be allotted to the promoters, but will not bear a dividend till the ordinary shareholders have received a dividend of 5 per cent. on their shares, nor will the Directors receive any fees until a dividend has been paid. Power is reserved to the Company to plant, raise, grow, purchase, and sell fruit and other trees, plants, flowers, or any market garden and agricultural produce, and to act as brokers and commission agents in the disposal of fruit and crops of every description; also to erect buildings, provide machinery, &c., in furtherance of the objects in view, and to preserve fruit by boiling, bottling, canning, drying, cooling, candying, and other methods of storing and preserving fruit, together with all other provisions that the wit of man can devise for rendering the undertaking successful. Messrs. Sampson Morgan, Emptage, Rawson, Gladstone and others may be expected to invest largely in shares in the Company, since they have endeavoured to show that fabulous profits are to be derived from the cultivation of fruit in this country; but, seriously, a well managed system of fruit-growing and distribution ought to be fairly if not highly remunerative. Mr. Richard Dean is the Secretary of the new Company.

— THE COLD STORAGE OF FRUIT.—As the experiments continue, it may not be without interest to briefly report progress. At the last meeting of the Committee, held on the 13th inst, John Lee, Esq., presiding, examples previously placed in the chill room were examined. The temperature of this room ranges about 35°. Figs, quite ripe when placed in store on August 30th, had kept surprisingly well; the dark coloured fruits appeared quite unaltered, but two of the lighter coloured were spoilt. Plums from Chiswick, stored at the same time, were as good as ever. Of a dozen outdoor Peaches, eight were in good condition, two fair, and two spoiled. Peaches and Nectarines grown under glass at Sawbridgeworth, also Oullins Golden Plums, placed in store at the same time (the 30th ult.) were in fine condition. Peaches from Messrs. Cheal & Sons, stored on August 31st, were in good condition, but a Melon with them was quite spoiled. Bradshaw Plums from Chiswick, placed in store at the same time, were unaltered, but Tomatoes, except a few yellow fruits, were spoiled. This is the second failure with Tomatoes, and they do not appear to be able to endure the cold. Many of the Cherries—a bad sample stored wet on August 8th—

were still sound, and it was thought that those which failed were crushed or injured at the outset. It is the opinion of the Committee that for keeping purposes the fruit must be free from blemish. Some of the Cherries (red) in the freezing room (temperature 21°) were quite hard; others (black) being yielding to the touch but frozen inside. Some Cherries taken from the chill room a fortnight ago and steadily thawed were good and well flavoured the following day after a cool sojourn of twenty three days, and there are doubtless others that have now been in the chamber forty days equally good. Can northern friends oblige by posting a few Gooseberries and Currants to Mr. D. Tallerman, Cold Storage Company, Leadenhall Market, 79½, Gracechurch Street, London? They will be gladly accepted and fairly tried. They should not be over-ripe, and packed to arrive without being bruised if possible. Peaches are best enclosed in tissue paper before being packed in boxes with wadding. All fruit is best stored in closed boxes as if for transit, as when exposed Cherries at least lose their bright fresh colour, and it would probably be the same with other fruits.—J. WRIGHT.

SEASONABLE OUTDOOR FLOWERS.

SUCH seasons as the present one teach us many lessons as to the best plants for unfavourable weather. For the guidance of amateurs I have jotted down the names of a few I have found suitable in the past season.

Leucanthemum maximum is a capital border plant growing 4 feet high; its deep green foliage forms a splendid base for its Marguerite-like flower heads, which are freely produced. They last long in water when cut, and readily mix with other flowers and grasses, and as a rule they are much prized by the ladies. This plant will grow almost anywhere where it is exposed to light; a strong soil suits it capitally. It is so thoroughly hardy that a large stock can be obtained in a short space of time by dividing the roots either in the autumn or spring.

Rudbeckia laevigata is rather uncommon in gardens. Where a graceful plant for either cutting or the decoration of the borders is a consideration, this *Rudbeckia* stands in a foremost position, its bright yellow flower heads and deeply cut leaves form a welcome contrast to brighter surroundings of more highly coloured flowers. This plant grows from 4 to 5 feet high, and flowers freely for at least two months.

Aetna spicata is well suited for the herbaceous border where plants 4 feet high are required. It grows in an upward direction, bearing long stout flower stalks, which branch into other shorter ones at intervals. Its creamy white blossoms show to advantage over the broad green leaves, which are produced freely. When once established this plant grows rapidly, but at first when in a weak state is a "miffy" plant.

Harpalum rigidum is another easily grown plant, reaching a height of 3 feet, sometimes more. Where yellow flowers are in request this *Harpalum* is one of the best, as it grows freely and flowers profusely, and is easily increased by dividing the roots.

Matricaria indora fl.-pl. is at the present time flowering abundantly, and has done so for the last eight weeks. A stock of plants is easily raised by inserting cuttings in sandy soil in a cold frame during the present month, choosing those cuttings which have not flowered, cutting them in 3-inch lengths. Allow them to remain in the frame until April, when they may be removed to their permanent position in the borders. Plants annually raised are preferable to the older plants, as the latter being so large require much space.—M.

LILIUM NEPALENSE.

AT the last meeting of Royal Horticultural Society's Committee one of the most distinct *Liliums* was exhibited that has been seen for a long time. *L. nepalense* has been heard of before, but flowering plants have not been previously seen in England, and Messrs. H. Low & Co. are to be congratulated on their valuable acquisition. The bulbs were received from a mountainous district in the East where the temperature falls below freezing point, and though the plants exhibited were only bearing solitary flowers, the same as plants from small bulbs of most *Liliums* do, yet the collector of *L. nepalense* reports that he has seen sixteen flowers on one stem. Therefore with more vigorous plants an increase in the number of flowers may be expected in this country. In both Paxton's and Johnson's Botanical Dictionaries *L. nepalense* is recorded as having been introduced into England from Nepal in 1825. In Dr. Wallace's work on Lilies it is said to have been "introduced in 1855, but not in cultivation in Europe at the present time" (1879). From this work we cite the following in reference to the re-introduced species, the remarks being taken from Baker's synopsis of the genus.

"*L. NEPALENSE*.—D. Don, Wern. Trans. iii., 412 ; Prodr. Nep. 52 ; Wallich, Pl. Asiat. Rer. iii., 67, 291, Cat. 5078 ; Kunth, Enum. iv., 267. — *L. ochroleucum*, Wall. in hb. Lindley.—Bulb, not known to me ; stem, 2 to 3 feet high, straight, slender, smooth ; leaves, 30 to 50 in number, scattered, of a shining green colour, ascending, smooth, lance-shaped, acute or linear, the lower ones 3 or 4 inches long, 6 or 9 lines broad in the middle, distinctly 5 to 7 nerved, the upper ones shorter and distant from each other ; flowers, solitary, or few in an umbel, slightly

of 7000 to 9000 feet above sea level, from Gurwhal and Kumaon to Nepaul. Wallich, Thomson, Jacquemont, &c."

The figure in Elwes' Monograph must presumably have been drawn from a dried specimen, and differs in colour from the flowers of Messrs. Low's plants, which is rich maroon only slightly broken, and the segments clearly tipped with greenish gold. The character of *L. nepalense* is represented in the engraving (fig. 29), and the plants and bulbs will doubtless be taken good care of by their possessors.

FIG. 29.—*LILIUM NEPALENSE*.

fragrant (pedicels with bracts at the base in a whorl of reflexed leaves), or few in a loose raceme, the lower pedicels ascending, 2 or 3 inches long, nodding at the top ; perianth, 4 or 5 inches long, broadly funnel-shaped, whitish-yellow, more or less tinged with purple on the inside, often marked with scattered dots ; segments, oblancoate-clawed, bluntish in the expanded flower, falcate in the upper third part, 6 to 12 lines broad at two-thirds of their length from the base ; stamens, shorter than the perianth by one-fourth ; anthers, narrow, 6 or 7 lines long ; pollen, yellow ; ovary, 9 to 12 lines long together with the style, a little longer than the stamens ; capsule, ovate, 2 inches long, obtuse-angled. Temperate regions of the Western and Central Himalayas, at an elevation

HYDRANGEA PANICULATA GRANDIFLORA.

JUDGING from the absence of this effective *Hydrangea* from the majority of gardens it is doubtful if its great decorative value is sufficiently appreciated, or the method of culture for having it in the best condition generally understood. Planted in shrubby borders where the soil either is, or is soon apt to become, exhausted, and the plants pruned in the bush form, they are in a measure effective ; but to see the huge trusses in all their beauty the plants should be grown in deeply worked and well enriched soil, cut down to the ground annually, and the beds well dressed with manure, then the vigorous growths and

magnificent trusses cannot fail to arrest attention in September. *Hydrangea paniculata grandiflora* is well grown at Chiswick, and some

grown together, can scarcely be lacking in effectiveness. Cuttings of half-ripened wood strike readily in sandy soil under handlights, and

FIG. 30.—HYDRANGEA PANICULATA GRANDIFLORA.

fine trusses were exhibited last week in the hall at Westminster. One of them, much reduced, is shown in the engraving, and it will be conceded that a number of such trusses on a plant, or a number of plants

well grown plants are attractive in pots early in the season, but the usefulness of this *Hydrangea* grown and treated as a hardy herbaceous plant is now more particularly alluded to.

THE APPLE AND ITS CULTIVATION.

Read by Mr. Hugh A. Pettigrew at a Meeting of the Young Men's Improvement Society, in the Castle Gardens, Cardiff.]

THE Apple (*Pyrus malus*) botanically belongs to the natural order of Rosaceæ, an order which contains all the best of our fruits, such as the Pear, Peach, Plum, Cherry, Strawberry, &c. It is found growing in a wild state in most of the temperate countries of Europe. But, like our grains and vegetables, it is not known from whence the first cultivated Apple came or who introduced it. The fruit is considered by authorities to be one of the healthiest grown in temperate climates.

There are several ways of propagating the Apple, but the most common is that of budding and grafting. The wild Apple, or Crab stock, is the best to bud or graft on, and for this purpose the fruit of the Crab is gathered in autumn, and stored in heaps outside mixed with sand to decompose. In the spring the seeds are sown in beds, and in the following year the plants are lifted and planted in nursery rows. In about three years after sowing they are large enough to be budded or grafted. Budding is generally practised by nurserymen, but those plants that fail to take are grafted in the following spring.

There are several stocks used for grafting the Apple on besides the Crab. There are small-growing varieties called the English Paradise, and the French Paradise or Doucin; varieties worked on these stocks never grow into large trees, and come into fruiting sooner than those grafted on the Crab, which is called the free stock on account of its vigorous growth. But I am inclined to think there are very few varieties now worked on the real Crab stock, as nurserymen generally procure the refuse from the cider press, which contains the seed of the cider Apple, and pass off Apple trees raised from these seeds as worked on Crab stocks.

Orchard trees should be planted at the distance of 30 feet apart each way. They should have clean stems of 6 feet before branching, and not be more than three years old from the time of budding. Trees that have stood in nursery rows for years, and have been pruned repeatedly to keep their heads within bounds, when lifted have scarcely any fibrous roots, and after planting become stunted and fail to make any growth for several years, whereas young vigorous trees planted at the age mentioned start into growth at once, and soon become large and fruitful. In planting, the pit should be made large enough to hold all the roots without being cramped, and a strong stake driven into the centre of it to tie the tree to. It should not be placed deeper than it was when growing in the nursery rows. It should be placed close to the stake, and the roots spread out on all sides, then covered with the finest of the soil, finishing with the rougher, then made firm and mulched with manure to exclude air and to keep down evaporation. In securing trees to stakes, which is important, means must be adopted for preventing abrasion of the bark.

The principal culture of these trees consists, after the first few years, in cutting out all the useless and cross branches, and top-dressing the ground with good manure to keep them in a vigorous and fruitful state. As young cattle and sheep are generally grazed in orchards and often injure the bark of the trees, I advise all, when making a new plantation to protect them with barbed wire cages, similar to those that are used here for protecting the avenue trees. They are much cheaper and answer the purpose better than any other kind of protection that I know. So much for the orchard.

In the kitchen garden Apple trees are planted and treated quite differently. The trees here are planted by the sides of the walks, some 6 to 8 feet from the Box edging, and 12 feet asunder or more to suit the quarter they are planted in. I have recommended that the orchard trees be three years old from the time of budding, but for planting in the garden I prefer maidens, or plants of one year's growth from the bud, to those of four or five years' growth, for the same reason that they will grow much faster than the older trees, and can be trained to the form desired much easier than those mentioned. To form pyramids they should be carefully planted and mulched, and the first year cut down to within 18 inches of the ground. The following year they will produce three to four shoots; the centre one should be retained to form a leader, and if vigorous left 18 inches long, and the other shoots which are to form the base or framework of the tree cut back to 1 foot in length; but a great deal depends upon the strength and ripeness of the wood. In all succeeding years the leading shoot will produce from four to five branches, and the central one of these should always be retained as a leader, leaving the others if well placed to fill up the sides of the tree. In pruning 1 foot or more should be left of the shoot according to its position and strength every year, and if possible it should be cut at a strong leaf bud which points outwards, and all the branches that cross each other or points towards the centre should be cut clean out

until the tree has attained its full size and shape, after which the trees may be spurred in regularly every year at pruning time to form fruit buds. I do not believe that stopping and pinching the young shoots during the summer adds to the productiveness of the tree; besides, it is impossible in large gardens where there is a great collection of trees to find time to do so.

I do not advise root-pruning to be practised except in cases where the roots have penetrated a cold, wet subsoil, in which the trees produce strong, rank, unfruitful wood. When such is the case, and the trees young, they should be lifted entirely, the strong roots cut back, and the fibrous roots spread out near the surface; but when the trees are large it is advisable to dig a trench some 3 or 4 feet distant from the trunk all round, cut back the strong roots, and add some good soil to encourage fibrous roots to grow near the surface. The foregoing remarks have special reference to the trees worked on the free stock.

Apples worked on the Paradise are generally grown as bush trees, espaliers, or cordons, and can be planted much closer together. They produce a few fine fruit when well grown, but the trees do not live so long nor produce the same quantity as either standards or pyramids, nor have they the same noble appearance. Their principal advantage is for amateurs with small gardens, where a great variety may be grown in a small space. They are pruned and trained somewhat after the style of Gooseberry bushes, open in the centre, and attaining the height of 6 or 7 feet.

Espaliers are trained on wire trellises, something similar to the way we train Pear trees on walls—they may be horizontal or fan shape, according to the taste of the cultivator. Cordons may be trained either single or double on wires on the edge of garden walks, or near the base of low walls, a foot or more from the ground. These trees are easily protected from frost or birds, which is one of the advantages claimed in favour of their culture, but they can never produce a sufficient quantity of fruit to make them popular with market gardeners.

I have said nothing yet about the insect pests or the diseases to which the Apple tree is subject. The canker is the most difficult to deal with. Some varieties of the Apple are more subject to it than others. When planted in low damp situations the trees get covered with moss and lichen. They are also subject to attacks of American blight, and this, in my opinion, is one of the principal causes of canker, but there is great diversity of opinion upon this. When once a tree is attacked with canker it is almost impossible to cure it. Moss and lichen can be destroyed by dusting the trees with newly slaked lime on a damp morning during the winter months, and American blight can be kept down by frequent syringings of petroleum mixed in water in the usual way, a glass of petroleum to a gallon of water. It should be kept in perpetual motion when being applied.

GATHERING AND STORING FRUIT.—Fruit for storing should never be gathered until it is perfectly ripe, which can be easily ascertained by cutting an Apple through the centre and examining the seeds; if they are found to be black they may be gathered with safety and stored in proper places.

I have often wondered why Apple trees have not been planted in our hedgerows. If landlords were to plant a certain number of the best and most suitable varieties in the hedgerows of every farm, and make an arrangement with the farmer to have them properly pruned and kept in good condition, also to replace any that died or met with accident, I have no hesitation in saying that they would produce enormous quantities of fruit; and further, that this system, if generally adopted, would in the course of twenty years become a source of wealth to the country, of which the farmer and the landlord would have a good share.

POTATOES IN 1888.

It may be thought early in the season to write about the Potato crop, but unfortunately the state of it even now is so pronounced as to fully indicate its condition, and that may be briefly described as very bad; indeed it is the most peculiar Potato year I ever experienced. I do not as a rule approve of monstrous Potatoes. They are not half so good as medium-sized tubers for the table, but for exhibition it is necessary to have them rather large and showy, and I grow a few every year for competition. These are produced in much richer soil than the general crop, and at the beginning of April last some were planted in compost that ought to have produced huge tubers, but in the best soil they have not gained the size generally attained by those in the ordinary quarters, and the latter are very small. In fact, all the Potatoes, like the Apples and Pears, are much below the average in size, and they will not grow any more now, as the leaves and stems have died down. Many of the early and midseason sorts have been quite withered in the stems since early in August, and now most of the late ones are in the same condition. This applies to gardens over a wide district, and

I notice that many of the field crops are all but stemless. This I regard as a peculiarity of the Potato crop of 1888. I never knew them to lose their stems so early and so completely before. It may be partially due to disease, but not altogether, as I notice some varieties which are very little diseased have lost their stems as much as those which are nearly wholly diseased. It seems to me that the excessive wet, cold, and absence of sunshine has caused the stems to perish so freely. Potatoes will not swell without a healthy stem and green leaves. Has this dying of the stems prematurely been general all over the country? It certainly has in our county, and while on a little judging tour lately I noticed the same thing in at least six other counties. The question will naturally arise, How will it affect the Potatoes? It has done so already in the smallness of them, and I am also of opinion it has interfered with the quality. Some varieties that were excellent on the table last year are the reverse this season, being soapy in texture and inferior in flavour, and I do not see any prospect of their improving. Further, the early dying down of the stems is certainly not in favour of the tubers maturing thoroughly for seed, and I fear the evils of this season will show themselves in an objectionable form in the crops of 1889.

I am greatly in favour of using no tubers for seed excepting those that have developed freely and matured thoroughly, but these will be difficult to find, and great care should now be taken that the tubers for seed are selected from the best ripened rows. We do not dig up all our Potatoes and select the seed tubers after the best have been picked out for use, but a few rows are left intact for seed, and this is a good way of securing fine planting tubers. In the month of June, when many of our early Potatoes were dug for use, two rows of each were left for seed, and as these were developed and partially ripened before the bad weather set in, we are sure of having a quantity of good early seed at least; but it is the midseason and late varieties that will be difficult to secure, and it is these that attention ought to be directed to now. The stems of these died down so fast that the ripening of the tubers did not keep pace with them, as is generally the case, and this year a ripe, or seemingly ripe, stem is no indication of a ripe root. We have proved this, as in digging some to see what the result of the decayed stems was, we found the skin quite loose on the tubers, and a slight friction brought it off. This is proof that they were not ripe, and I would not dig and store Potatoes in this condition, as they would not keep well, and although they may not mature much more if left in the ground the skin will be sure to become firm, and this is an advantage.

The disease is more general and severe this season than it has been for seven years. Last year we lifted several tons of tubers, and a hat box would have held all the diseased ones we could pick from them, but this year half of some sorts are diseased; others are not so bad, but all are affected, and a well known gardener was telling me the other day that three parts of his crop was destroyed. It is therefore a year when disease has to be taken into account, and there is no resisting it. Some amateurs in the neighbourhood cut all the stems off level with the soil so soon as the leaves began to spot and wither, and I think these are now the worst diseased. Others trod the ground very firm over the top of the drills. That was useless. In short, the murrain has run its course, and we are as helpless to resist it as if such a thing as curing the Potato disease had never been suggested; but we ought to do our best with the sound tubers, and advantage should be taken of dry days to dig and store the crop. Do not attempt to gather them as they are turned out, but throw them on the surface on a fine morning, where they can be exposed to the sun and wind to dry. This is a good stride towards their successful storing, as unless they are stored dry they will not keep well during the winter. It is also of the greatest importance that the bad tubers be separated from the good, and the best time to do this is when they are spread out on the land after digging.

The best place for storing Potatoes when newly lifted is in a dark but airy shed, and if they have to be placed in a light shed for a time they should be covered with straw. This is better than sheets or mats, as these retain the moisture too much. We shall this year store Potatoes for use that would have been given to the pigs last year as being too small for the kitchen.—A KITCHEN GARDENER.

COMMERCIAL FLORICULTURE AND AMERICA.

[Read before the Massachusetts Horticultural Society by Mr. W. J. Stewart of Boston.]

(Concluded from page 218.)

Is it surprising that horticultural exhibitions, pure and simple, appear to be losing ground? The time when people would crowd into a hall and gaze with open-mouthed wonder on a table covered with dishes of Pears, and Radishes, and Apples, or rows of bottles filled with a variety of flowers, is past and gone. Commercial floriculture gives the people a free exhibition every day throughout the winter in the florists' windows on Tremont Street such as in the horticultural exhibitions of a few years ago was never dreamed of. The same is true of fruit. The Italian fruit-stands on our street corners, with their loads of Strawberries in April and May, and of Peaches and Water Melons in July, would have been worthy of an admission fee twenty-five years ago. Even Orchids as rare novelties have seen their best days. The commercial florists have their eyes on the Orchids, and they are doomed. They will not long be the flower of the few. Not all of the work done by the florists, however, has been in the direction of art or good taste. We have seen floral designs, so called, which were nothing but hideous monstrosities; and such things have given the critical a fair foundation for wholesale denunciation of the whole business. Perhaps the

best way to remedy this state of affairs is to educate the public to a higher appreciation of work that is really artistic.

Floral designs need not be monstrous, and many even that are formal can be made beautiful in the hands of a true artist. Here is the opening for the successful floral exhibition of the future. At the recent Orchid Show held in New York, the most noticeable feature and that which went farthest towards making it a success was the manner in which the grouping was done. Everything was arranged with an eye to artistic effect, so that altogether it made one perfect and harmonious whole. Luxuriant banks of Ferns filled the shady corners, while beautiful Pitcher Plants hung above. Orchids which grow naturally in the air were attached to old mossy branches overhead, while under the shade of Palms and Tree Ferns whole colonies of Cypripediums peeped forth from verdant banks. After seeing such a picture, no one would think of going back to the old style of exhibition where each contributor sets up his own row, and the result is a lot of loose ends and detached groups without harmony or system, and what might otherwise be a grand and beautiful display is completely spoiled for lack of a comprehensive plan and a master hand to carry it out.

Within the past three years a remarkable movement has been taking place among the florists. They have not only a national society which is already a magnificent organisation, but they are uniting in different cities all over the country into Florists' Clubs, so called. What is the cause of these simultaneous movements, and what will be the result? I think the cause is principally that the commercial florists find that the horticultural and agricultural societies and similar organisations, from their very composition and nature, cannot adequately represent or serve the best interests of so large and progressive an element. The gentleman of leisure with his few dozen of pet Raspberry bushes will carefully pick off a couple of quarts of fruit and bide him to the city; occupying his whole Saturday forenoon with arranging them in a dish on a table, and watching with jealous eyes the dish of his neighbour alongside. Another will buy a couple of baskets of Verbenas in the spring, take them home, and plant them in his little front garden, and when they come into flower he too will start for the city with his Verbena flowers, which he will stick into a row of bottles, and then hang around to see whether the committee will not recognise his self-denial by placing upon his exhibit a considerate one dollar gratuity. But commercial florists have no time or inclination for such trifling. It is too far behind the times. Regarding essays and discussions, there are so many questions that are all-important to the commercial florist of 1887 that he cannot afford to divide the time with the market gardener, the farmer, and the fruit grower.

When the Massachusetts Horticultural Society was organised floriculture was but a babe in this country. There was nothing to be made from it pecuniarily. Its members had but little in the way of precedent or example to encourage them, and it mattered not whether they were carpenters, farmers, or dry goods dealers; they were welcome so long as they thought enough of horticulture to use their money and their efforts for the good cause. All honour to them. They builded better than they knew; and what more can be wished for the new organisations than that at the close of an equal period of time they may be able to point to a record of usefulness equal to that which is the pride of the Horticultural Society? If it had not been for this and kindred societies commercial floriculture would not have been what it is to-day. But, as the child when grown to robust stature leaves his father's home and strikes out to make his mark in the world—as the thriving offshoot from the potted plant, finding its quarters cramped, must be taken away and put in a place where its ambitious vigour can find room to work, so the commercial florists, as they feel their strength and as they begin to know their needs, strike out for themselves in order that they may devote all their time and their best energies to those questions which most concern their own welfare. They do not by this action sever the ties that bind them to this paternal home. They will be seen and heard here, and you will find them all the better sons for having got away from their leading strings and proved their own strength.

They are now taking a lesson in self-reliance and independence—not as individuals, but as a body. The influence which can be exerted by such a union of interests, and the pressure which can be brought to bear wherever and whenever it is necessary, were shown in Congress last winter, when an oppressive bill to double the postage on seeds was withdrawn, chiefly through the efforts of the Society of American Florists. There is plenty of work for them that has not yet been touched. The disgraceful practice of sending out goods under false names, which has flourished in so many quarters, must be attacked with vigour and fought relentlessly until this stigma is removed from the reputation of American dealers; and the travelling impostors who have been going over the country unmolested for years, with their gaudy pictures of flowers the like of which never grew, will soon find the place too hot for them.

The florists are at last beginning to think and act for themselves, and substantial benefits cannot fail to follow for them and for the public. It has been a long struggle for them. Hard work all day and often all night, without a holiday and with scarcely a Sabbath that they can call their own—this has always been, and to a certain extent always must be their lot. These men who have reversed the seasons and have turned dreary winter into a long summer day, whose vocation is to make the home brighter, to add to the beauty and joy of the bridal festival, to cheer up the sick room, and to lessen the loneliness and desolation of the funeral, have come up from very humble beginnings. What they now have has been well earned, and the business of which they are to-day

proud has come not by chance or good fortune, but is the result of application, perseverance, and patient toil.

HORTICULTURAL SHOWS.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

At the autumn Show of the above Society, held in the Waterley Market, Edinburgh, fruit as usual formed the principal feature, the number of classes provided therefor being seventy-six. For plants there were fifty-three classes, six of which were confined to trade growers; cut flowers were provided for to the number of thirty-six classes, nine of which were for nurserymen; and for vegetables twenty-three, the latter being, perhaps, better represented than any other section of horticultural produce. The Council also offered prizes for bees and honey; but the exhibits of these were of a very limited character. Coming more particularly to the several sections, that devoted to fruit was found to be generally poorly filled, and although with a few outstanding exceptions the quality was like the quantity—below the Edinburgh standard. For the prizes offered for four collections of fruit there were only nine staged altogether. For twelve dishes Mr. Hunter, Lambton Castle, Durham, was the only exhibitor, and received the first prize for a good collection, in which were three good clusters of Black Hamburgh, three Alicantes, one Gros Guillaume, and two of what were apparently Gros Colman Grapes. Two fine dishes of Peaches, Apples, fine Marie Louise d'Uccle Pears, good Nectarines, Melons, &c., were also staged. The same exhibitor was also first for eight dishes of fruit, comprising a fine Smooth Cayenne Pine Apple, good Gros Colman (?) and Duke of Buccleuch Grapes, Best of All Melon, extra Brockworth Park Pears, fine Princess of Wales Peaches and Elrue Nectarines, and a dish of fine Worcester Pearmain Apple. Mr. McKelvie, Broxmouth Park, Dunbar, was second, and Mr. McIntyre, The Glen, Peebles, third.

For a collection of twelve dishes of open air fruit Mr. Fairgreive, Dunkeld Gardens, was easily first with good Apricots, Williams' Bon Chrétien and Jargonelle Pears, Hales' Early Peach and Early Louise Peaches, Victoria and Kirke's Purple Plums, Morello and Late Duke Cherries. Mr. Low, gardener to J. Paton, Esq., Viewforth, Stirling, was second. For a collection of twelve dishes of orchard house fruit Mr. Hunter was the only exhibitor. The most noteworthy dishes were some remarkable Beurré Diel and Pitmaston Duchess Pears, each said to weigh 32 ozs. to 35 ozs. each, very fine Queen Apples, and Warner's King and Ecklinvilles, with Peaches, Nectarines, Plums, and Figs.

A first prize of £10 was offered by Messrs. W. Thomson & Sons for eight bunches of Grapes, and this and the other good prizes offered by the Society brought out the only really brisk competition, six growers staging. The premier ticket was finally placed on the Grapes exhibited by Mr. McHattie, gardener to the Marquis of Lothian, Newbattle Abbey. These were large clusters averaging 4 to 5 lbs. each, and consisted of extra fine Black Hamburgh, Madresfield Court of high quality, magnificent clusters of Muscat of Alexandria, and very fine Duke of Buccleuch. Mr. McKinnon, gardener to Viscount Melville, Melville Castle, Lasswade, was a very close second with smaller better finished bunches, which might have very well been placed first by a different set of judges. Alicante, Gros Maroc, beautiful Golden Hamburgh and Muscat of Alexandria, a little late, were the leading varieties staged. Mr. Boyd, gardener to A. Forbes, Esq., Callender House, Falkirk, was third, and Mr. McKelvie fourth, with Grapes better than the preceding, but spoiled by a crushed example of Golden Hamburgh. For four bunches Mr. McHattie and Mr. McKinnon held the same position as in the previous class, and with the same class of Grapes. For two bunches of Muscat of Alexandria Mr. McHattie was first with fine clusters, and Mr. McKelvie second with good examples. The last-named was first for two Black Hamburgh, extra fine, Mr. McHattie second, also fine. For one bunch of Muscat of Alexandria, Mr. Green, gardener to the Marquis of Tweeddale, Yester, was first. Black Hamburgh were a well filled class, Mr. Copeland being first. Mr. McKinnon was first with extra finely finished Black Alicante. Mr. Boyd had the first for Alnwick Seedling; Mr. Murray, Polmont, for Gros Colman fine, and Mr. McHattie for Lady Downe's. Mr. McKinnon had first for Madresfield Court, and Mr. Potter, gardener to Mrs. G. Moir, Carlisle, with extra fine Buckland Sweetwater was first in the any other class of white. Mr. Murray's Gros Colman was the finest "bloomed" Grape in the Show.

Of Pine Apples there were several good fruit, Mr. McIndoe, Hutton Hall, Yorks, being first with a very fine Queen. In the class for that variety Mr. McIntyre first for one Smooth Cayenne and also for two Pine Apples. Peaches formed a large and beautiful show, Mr. McLeod, Brentham Park, Stirling, being first with Barrington. The best Nectarines were fair examples of Humboldt, from Mr. Harkness, Broadmeadows, Berwick. Apples were generally small and green, with the exception of some fine orchard house fruit. To Pears the same remark applies. Of small fruits there was a large and excellent display.

Among plants the principal prizes went in the nurserymen's classes to Messrs. R. B. Laird & Sons, and Messrs. Ireland & Thomson for very fine tables. Mr. Grossart was first in the corresponding class for gardeners. For six flowering plants Mr. Patterson, Millbank, staged examples of *Ericas obbata*, *retorta major*, *tricolor* Wilsoni and *Marnockiana*, *Lapageria rosea*, and *Statice profusa*. The same exhibitor also took the prizes for *Ericas* with small well-flowered plants. For four Orchids Mr. Currer, Eskbank, took first, having a fine *Cattleya Dowiana* with five blooms, a large *C. Gaskelliana*, *Miltonia spectabilis*, and *Cypripedium Spicerianum*. Mr. Grossart second. For one Orchid Mr. Brotherston, gardener to the Earl of Faldington, Tynninghame, East

Lothian, was first with *Phalaenopsis amabilis* with a strong spike. Mr. Currer second with a fine *Cattleya Gaskelliana*. A good *Renanthera Lowi* was also exhibited by Mr. Laing. The six Ferns with which Mr. Grossart secured first prize and a challenge cup were fresh good plants.

Of cut flowers the display was limited, and generally below the average in quality. No *Gladiolus* were shown by nurserymen; several lots were staged by gardeners, but with the exception of the first prize twelve all were inferior. Dahlias were very fine in both sections, Hollyhocks poor. Some very fine cut *Chrysanthemums* were also staged, but the great feature of this section was undoubtedly the Roses, more particularly those staged by Messrs. Cocker & Sons, Aberdeen, this firm taking first both for thirty-six and for eighteen blooms. The blooms were large, young, of beautiful shape, and exquisite colouring. Particularly noteworthy were Her Majesty, Mrs. John Laing, Baron A. de Rothschild, E. Y. Teas, *Senateur Vaisse*, *Violette Bouyer*, Duke of Teck, and A. Rigotard. Mr. Dickson, Belfast, who was second for the thirty-six, had also a fine stand, but blooms older and hardly so fine as the "Aberdonawa." Mr. Croll, Dundee, was second for eighteen buds, with good examples. Mr. Henderson, Clermiston, had the best Roses in the gardeners' section.

Vegetables were largely shown, though to nothing like the extent of last season. For Messrs. Sutton & Sons, of Reading, prizes, seven exhibitors staged collections, every one of which were of superior quality. The best lot came from Mr. Low, Viewforth, Stirling, Celery, Leeks, Onions, Tomatoes, grand Carrots, French Beans, and Peas being especially noteworthy. Mr. Cairns, Jedburgh, held second place also with a grand collection. Mr. McKinlay third, and Mr. D. Logan, Coldstream, fourth. The best collection of salading came from Mr. McKinlay, Blackwood, Lesmahagow. Mr. Milne, Leith, second. Large quantities of fine Celery, Leeks, Peas, Cucumbers, Potatoes, &c., were staged in competition for the prizes offered for special sorts of vegetables.

Among the miscellaneous exhibits an attractive table of seedling Begonias was arranged by Mr. Donnie, Pink Hill. Messrs. Methven and Sons, Leith Walk, contributed a large table of stove and greenhouse plants. From Messrs. Dicksons & Co., Waterloo Place, a table of plants with various florists' flowers—Pentstemons, Pansies, Roses, and Carnations, among the latter of which were blooms of a new variety named Maggie Lauder, which was awarded a certificate. The blooms were much like Mary Morris in appearance. Messrs. Stuart & McIn of Kelso had a table devoted entirely to florist flowers, among which were some very fine Pentstemons, striped Antirrhinums, French Marigolds, &c. Messrs. Munro & Ferguson, St. Andrew Square, contributed a table of cut herbaceous spikes. Mr. Henry Erskine, George Street, Makart bouquets and beautiful crosses, wreaths, and bouquets which is a speciality of this establishment. From Messrs. Laing & Mather, Kelso, came a few dozen good Picotees and Carnations, and a large quantity of their new yellow and rose Carnation R. H. Elliot, a bright looking sort, which attracted much attention, and which was favoured with a first-class certificate. Mr. Campbell, High Blantyre, exhibited a large collection of fine Carnations and Picotees in all the best old and new varieties. The Show was very largely patronised by the public, the large market being several times inconveniently crowded during the course of the two days during which the Exhibition was open.

BRIGHTON.—SEPTEMBER 12TH AND 13TH.

For many years the Brighton Horticultural Exhibitions, under the management of Mr. Edward Carpenter, have afforded representative displays of Sussex gardeners' skill. The competition has by no means been confined to the county either, for the prizes offered have tempted exhibitors from a long distance. Plants, flowers, and fruits have been well shown, the last named being especially good at the September Exhibition. Nurserymen have contributed liberally with non-competing groups of plants, &c., but there has been one serious defect in recent years—the number of visitors has decreased, and the receipts have been correspondingly reduced. It is difficult to account for this. The site is an admirable one, for the rooms and gardens at the Pavilion can be made to accommodate an extensive display of the choicest and most delicate produce. The building itself is an interesting one and convenient of access. It is true the rooms are somewhat dark, but when lighted at night they have a beautiful appearance. It would seem that either the Show is not sufficiently advertised in the town or that the price of admission is too high, and perhaps it would be advisable to try the effect of a little more liberality in both respects.

Plants at the Show on Wednesday and Thursday last were not so numerous as usual, but one good-sized tent was allotted to them, while several collections were also staged in the Pavilion rooms. Messrs. Knight & Co., Hastings, had the best six stove and greenhouse plants, followed by Mr. Meachen, gardener to Mrs. Armstrong of Woodslee, both showing specimens of the usual character in these classes. Messrs. Knight & Co. were also first for six Heaths. In the amateurs' classes Messrs. Townsend, Meachen, Moody, Curry, and Collis won the chief prizes. Groups of Ferns have frequently been a beautiful feature at the Brighton shows, but this year only one was staged—namely, that from Mr. W. Miles, West Brighton, which fully merited the first prize awarded. Fuchsias, Pelargoniums, Tuberous Begonias, Orchids, Gloxinias, and fine-foliage plants were shown by Mr. J. Barnes, Alexandra Villas, Mr. Meachen, and Colonel Pepper, Milford Hall; groups arranged for effect coming from Major Way, Wick Hall Hove, Mr. Meachen, Messrs. Stringer & Co., and Mr. H. Head, who secured the prizes in the order named.

Cut flowers were abundant, bright and beautiful; Roses from Messrs. Perkins & Son, Coventry, Paul & Son, Cheshunt, and T. Bunyard,

Ashford, looking unusually fresh and good for the season. Dahlias of all classes, single Pompon, Show, Fancy, and "Cactus" were excellent, Messrs. Keynes, Williams & Co., Salisbury; Cheal & Son, Crawley; and Paul & Son taking the leading prizes. Asters, Gladioli, and collections of hardy herbaceous flowers also occupying much space.

Fruit was admirably represented, the general quality being superior to what could have been expected this season. For a collection of twelve dishes of fruits Mr. Ward, gardener to the Earl of Radnor, Longford Castle, Salisbury, was adjudged first honours, closely followed by Mr. C. J. Goldsmith, gardener to Mrs. C. A. Hoare, Kelsey Manor, Beckenham. Messrs. Ward, Baker, Godley, Osman, and Goldsmith shared the honours for black and white Grapes. Pine Apples, Plums, Peaches, Nectarines, Cherries, Melons, being largely shown by the exhibitors already named, with Messrs. Richards, Dunearn, Gilmour, and Mundell.

The non-competing exhibits were numerous, the local nurserymen contributing largely both of cut flowers and plants.

CHELTHENHAM.—SEPTEMBER 12TH AND 13TH.

THIS was generally considered the best and most successful Exhibition yet held by the County of Gloucester and Cheltenham Royal Horticultural Society. The Winter Garden is admirably adapted for horticultural displays, and thanks to Mr. J. Cypher and a few other plant exhibitors, and a great number of competitors with cut flowers, fruit, and vegetables, a grand effect was produced. Mr. W. H. Bridgewater proves a most efficient Secretary, and much credit is due to him for the admirable arrangements made.

In the most important plant classes Mr. J. Cypher had matters very much his own way, but it is doubtful if anyone could have wrested premier honours from him, so good was everything that he staged. His collection of six flowering plants consisted of large and fresh specimens of *Ericas Eweriana* and *Thompsoni*, *Clerodendron Balfourianum*, *Statice profusa*, *Bougainvillea glabra*, and *Paneratium fragrans*. The last named was a grand plant with nine immense spikes of bloom. Mr. J. F. Mould, Pewsey, was second, and Mr. Mackie, gardener to Mrs. Ruddie, Tewkesbury, third. For a collection of thirty plants in or out of bloom Mr. J. Cypher was well first, this grand bank of plants being quite a feature in the Show. It included several fine *Kentias*, *Latanias*, *Cycads*, *Crotons*, all in good health and colour, as well as many fine *Ericas*, *Clerodendrons*, *Bougainvilleas*, and other well-flowered plants. Messrs. Heath & Son, Cheltenham, were awarded the second prize for a creditable group, the third prize going to Mr. J. F. Mould. Mr. Mackie was first in the open class for six Tuberous Begonias, and Mr. H. Chapman second; and in another class for Begonias, not open to nurserymen, Mr. Enos Smith, gardener to Mrs. Pil rim, was first, and Mr. C. Hill, gardener to Mrs. McNeale, second, the exhibits being most praiseworthy in each instance. Mr. Lewis, gardener to Mrs. Lingwood, had a first prize for *Achimenes*, and also for Zonal Pelargoniums, Mr. Mansfield, gardener to Mrs. Gillilan, taking the second prize in the latter class. Fuchsias were poorly shown, Mr. Sparkes being awarded a second prize only. Mr. J. Cypher took the lead with exotic Ferns, Mr. E. Smith being a good second, and the last named was first for eighteen varieties of British Ferns, Messrs. Heath & Son second, and Mr. C. Lodge third.

There were several classes for cut flowers, in all of which the competition was close and good. Messrs. Heath & Sons were well first for twenty four Dahlias, Mr. T. Hobbs, Bristol, being second, Mr. W. Shaw, Kidderminster, third, and Mr. J. Humphries, Chippenham, fourth. Mr. G. S. Walters, Calne, took the first prize in both classes for Asters, Messrs. T. Evry, and Campbell, Bath, obtaining the remaining prizes. The best twelve varieties of Roses cut in loose bunches of three were staged by Messrs. Heath & Son, Mr. Hobbs being second, and Messrs. Jefferies & Son, Cirencester, third. Mr. G. S. Walters was well first for twelve spikes of Gladioli, and the exhibits of Mr. A. A. Walters, Bath, who followed, and of Mr. T. Spence, gardener to H. Moffat, Esq., Goodrich Court, the winner of the third prize, were also praiseworthy. In the class for twelve bunches of hardy herbaceous flowers Mr. J. Cypher made a grand display, and were easily first. All were cut with long stems and arranged most effectively in a bank of moss, a welcome innovation well worthy of general imitation. Messrs. Heath & Son were second, and Mr. W. Smith third. Very beautiful and attractive also was the ornamental basket of plants which gained Mr. Cypher the first prize. In this instance Mr. Wonson, gardener to Mrs. Thompson, was second, and Mr. C. Hill third; both having prettily arranged baskets.

Fruit was extensively shown, the quality generally being very good, and probably nowhere else would such low prizes, with the exception of one class, attract so much competition. An extra class was provided for a collection of nine dishes of fruit, from which Pine Apples were excluded, and this attracted nine competitors from various parts of the country. The first prize, value £10, was won by J. Dawes, gardener to M. Biddulph, Esq., M.P., Ledbury, who had fairly good Grapes and excellent Peaches, Figs, and other choice fruit. Mr. W. Child, gardener to the Earl of Coventry, Croome Court, Severn Stoke, was awarded the second prize of £5, the third prize of £2 going to Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, Derby, the exhibits in each instance being excellent. An extra prize of £5 was given to Mr. W. Pratt, gardener to the Marquis of Bath, Longleat, who, but for an unfortunate error in staging nine instead of twelve Plums in a dish, would have just won the first prize. The Grapes and Melons in Mr. Pratt's collection were very superior. For a collection of six varieties Mr. Child was first, Lord Wantage second, and Mr. Siddall third; and with four dishes Mr. Arkell, gardener to A. J. Shinner, Esq.,

was first, Mrs. Groves second, and Mr. A. James, gardener to the Rev. A. Coventry, third, all staging creditably. The prizes for Grapes were much too low. For instance, the first prize for six bunches of black Grapes in two varieties was only £1, and the least that ought to be done in the future is to double that sum and reduce the number of bunches to four. With greater liberality in this direction the Cheltenham Autumn Show would be one of the most noted in the country. Mr. C. Froud, gardener to the Rev. Canon Coventry, was placed first in all four classes for Grapes, and prizes were also taken by Mr. A. James, gardener to the Rev. G. Coventry, Mr. J. Dawes, Mr. Mackie, and Mr. E. Green, gardener to Major Bertie Roberts. There were also well-filled classes for Apples, Pears, Peaches, Nectarines, Melons, and other fruits, most of the prizewinners being found among the names already given. Altogether a capital show of fruit was on view.

Vegetables are always exceptionally well shown at Cheltenham, the competition in the classes for collections and also for single dishes being very keen and close. Mr. Arkell was first for a collection of nine dishes, and was remarkably successful in various other classes. Several prizes were also won by Mr. J. Turk, Mr. A. James, Mr. Tiley, Mr. J. G. Kitching, Mr. A. Cook, Mr. T. Evry, and Mr. Child. There was good competition for the special prizes offered by Messrs. Webb & Sons, Wordsley, for a collection of six varieties, Mr. Arkell taking the lead with very fine examples, among which some of Messrs. Webb's novelties were very prominent. Mr. T. Evry was second, and Mr. A. James third. For Messrs. Sutton & Sons' prizes the competition was equally good, Mr. Arkell again being first, Mr. Child second, Mr. Wonson third, and Mr. J. G. Kitching fourth.

GLASGOW AND WEST OF SCOTLAND.

THE autumn Show of this Society was held within the International Exhibition Grounds on the 12th, 13th, and 14th inst. Plants and fruit completely filled the grand hall, two large marquees erected in the grounds being devoted to cut flowers and vegetables. The entries were so numerous that a considerable number had to be put on tables in the open air. It is safe to say that no finer display has been seen in Glasgow since the "International" about sixteen years ago; indeed the Show was so large that it is only practicable to report the prizewinners in the open classes. The platform was decorated by Mr. R. Bullen, Curator, Royal Botanic Gardens, and was done admirably. Grand specimen Palms formed the background of the bank, finishing off at the lower part with *Adiantums* in perfect condition. An Orchid in the centre of this group, *Lisoechilus giganteus*, attracted much attention, this being the second time it has flowered in Europe, a specimen in the possession of Sir Trevor Lawrence flowering last year for the first time. At the opposite end of the hall, and surrounding the Royal Throne, Messrs. Little & Ballantyne, Carlisle, had a collection of *Crotons* and other fine-foliaged plants, grandly coloured specimens of *C. Williamsi*, *C. Queen Victoria*, *C. Warreni*, *C. Disraeli*, interspersed with nice plants of *Asparagus plumosus*—a charming arrangement that will not readily be forgotten. Messrs. Wylie & Lochhead kindly granted the use of this portion of the hall, and were well rewarded, as it was one of the most interesting features of the Exhibition. A large table of flowering plants and Ferns were on exhibition from Messrs. Smith & Simon. Messrs. Austin & McAslan contributed a similar table, as also a capital collection of Apples from their new nurseries at Cathcart; both collections were very highly commended. Mr. Wm. Kidd, gardener to R. B. White, Esq., Ardarroch, Garelochhead, exhibited a fine stand of *Allamanda* blooms and a beautiful stand of Orchids, including some finely coloured *Cattleyas*—*C. Gaskelliana*, *C. speciosissima*, and *C. Loddigiesi*. *Lælia elegans* *preciata* was very conspicuous, the labellum being very richly marked. Among other fine plants were *Cypripedium Spicerianum*, *Miltonia spectabilis*, and *Odontoglossums*, a very highly commended exhibit. An observatory hive, showing bees at work, came from Wm. & J. D. McNally, Glenluce.

PLANTS (open to all).—With a group of plants arranged for effect, space about 300 square feet, Messrs. J. & R. Thyne won the first prize with a tasteful arrangement. The only other competitor in this class was Mr. Jas. Bryson, nurseryman, Helensburgh. A more spirited competition took place for the ten specimen plants, six foliage and four in flower. Mr. Jno. Sutherland, Victoria Nursery, Lenzie, secured the first position. Among his best plants were *Davallia Mooreana*, 7 feet through, a magnificent plant; *Croton Chelsoni*, finely coloured; *Erica Marneokiana*, *Kentia Canterburyana* and *Fosteriana*, and a grand plant of *Gleichenia flabellata*. Mr. R. Grossart, Oswald Gardens, Edinburgh, was second; his plants were smaller, but very fresh. *Davallia filicoides* *plumosa* was very fine; *Erica retorta* *major*, *Anthurium Knighti*, and *Kentia Fosteriana* were also very good. Mr. Paton, Kilmarnock, had the third prize, his best plant being a huge specimen of *Cycas revoluta*.

For six stove or greenhouse plants in flower Mr. Hugh Millar, gardener, Auchinraith, Bothwell, was first; a magnificent *Phœnoeoma* was his best plant. Mr. Raeside was first with six fine-foliage plants, Mr. Geo. Neil, Greenhead Street, Newmilns, first for the best six exotic Ferns, and the same for three *Ericas*. Mr. Jno. Mathieson, gardener to J. L. Henderson, Esq., Westbank, Partick, had the best Palm. Mr. D. Wilson, gardener to Hugh Steven, Esq., Westmount, was again successful in carrying off the first prize for three Orchids, a good plant of *Oneidium macranthum* and two *Odontoglossums*, *Alexandra* and *odoratum*. Mr. John Sutherland had the best six Pitcher Plants, *N. sanguinea*, *N. Lawrenceana*, and *N. Henryana* being his best plants. For twelve table plants, foliage, Mr. Jno. McIntyre, Woodside Gardens, Darlington, was first with an exceptionally fine lot, Mr. R. Grossart

being first for six table plants in flower, and Mr. James Bryson first for six table plants, distinct varieties.

TABLE DECORATIONS.—The best decorated dessert table brought out five competitors. As the flower glasses and cpergnes were mostly on loan from the exhibitors in the "International" the effect of the tables was very much enhanced, these being all of the most costly description. The first prize was awarded to Mr. D. McIntyre, late gardener to C. W. Cayzer, Esq., Mansfield Street, Glasgow. The centre of the table was crowded and the flowers somewhat coarse. The second prize went to Messrs. McDougall & Sons, Buchanan Street: the arrangement was lighter with the exception of the centre stand, Messrs. J. & R. Thyne, St. Vincent Street, being third with an exceedingly beautiful arrangement. Orchids and Roses were the only flowers employed, relieved with the green of Asparagus plumosus. Large dinner knives had unwittingly been laid down, which completely marred the superiority of the table in other respects.

CUT FLOWERS AND BOUQUETS (open to all).—Twenty-four Dahlias, distinct varieties, the first prize went to Mr. W. Boston, Bedale; Mr. Nicholas Walker being second, and Mr. M. Campbell third. For twelve bunches of single Dahlias, Mr. N. Walker, florist, Gateshead, Low Fell, was first; Messrs. Laird & Sons, nurserymen, Edinburgh, second; and Mr. Campbell, nurseryman, Blantyre, third. Messrs. Alex. Kerr & Sons, Katemouth, Roxburgh, were first for six spikes of Hollyhocks, and first for six blooms. The spikes reminded us of exhibits twenty years ago, when the Hollyhock was shown to perfection. Gladioli were well shown by Messrs. McGredy and Messrs. A. Dickson & Sons, who were first and second in the order named, Mr. N. Walker being third. With twenty-four blooms of Roses Messrs. James Cocker and Sons, Aberdeen were easily victorious; Messrs. D. & W. Croll, Broughty Ferry, second; Messrs. Alex. Dickson & Sons third. Mr. John Sutherland, Victoria Nursery, Lenzie, was successful in carrying off the first prize for twenty-four blooms of Show Pansies, distinct, and also for twenty-four blooms of Fancy varieties. Messrs. M. Campbell and A. Lister were second and third for the Fancies, Mr. Alex. Ollar, Campeltown, being second for the Show Pansies. Carnations and Picotees made a grand display. The first prize was gained by Mr. W. Campbell, Blantyre, with twenty-four blooms of very superior merit, Mr. N. Walker, Gateshead, being second; Messrs. Aitken & Sons, Lenzie, third. Messrs. Perkins and Sons, Warwick Road, Coventry, were successful in the bouquet classes, taking first for a basket of assorted flowers, hand bouquet and bridal bouquet.

FRUIT (open to all).—Sixteen dishes of fruit, not more than four dishes of Grapes, distinct, Mr. Thos. Boyd, Callander Park Gardens, Falkirk, was first with a grand collection. His Grapes were in splendid condition, good bunches, and perfect in bloom; especially noteworthy in the collection were three bunches of Alnwick Seedling, three bunches of Muscat Hamburg, three of Black Hamburg, and three of Black Alicante Grapes, Queen and Smooth Cayenne Pines, Barrington and Lord Palmerston Peaches. Mr. J. McIndoe, Hutton Park, Guisborough, had to be content with second place, and Mr. J. McIntyre, Woodside, Darlington, third. Mr. M'Kelvie, Broxmouth Park, Dunbar, carried off the first prize for eight dishes of fruit, Pine Apples excluded, Shipley Apricot, very fine; Late Admirable Peach, Brown Turkey Figs, Kirke's Plums, Humboldt Nectarine, Best of All Melon, Alnwick Seedling and Muscat of Alexandria Grapes. Mr. P. W. Fairgrieve, Dunkeld, was second, and Mr. Donald McBean, Craigends, third. The leading prize for six dishes of hardy fruit was gained by Mr. P. W. Fairgrieve with grand dishes of Elruge Nectarines, large early Apricot, and Pond's Seedling Plum, &c. Mr. Brown, Abercainrey Gardens, Crief, was second, and Mr. A. Wilson, Auchincruive Gardens, Ayr, third.

Grapes, eight bunches, at least four dishes distinct varieties, Mr. Geo. M'Kinnon, Melville Castle Gardens, Lasswade, was first with grand bunches of Black Alicante, Muscat of Alexandria, Gros Maroc, and Alnwick Seedling. Mr. M'Kelvie second; Mr. W. Murray, Parkhall Gardens, Polmont, third. Mr. M'Hattie, Newbattle Abbey Gardens, Dalkeith, had first prizes for two bunches of Black Hamburg Grapes, two bunches of black Grapes any other variety, and two bunches of white Muscat Grapes, and twelve Figs. Mr. M'Kinnon, Melville, was also first for two bunches of Alicante, and for two bunches of white Grapes other than Muscat. Mr. W. Murray, Polmont, was first for two bunches of Gros Colman; the same exhibitor had the heaviest bunch of Grapes, Trebbiano, which was marked 19½ lbs. weight.

Mr. R. Grossart, Oswald Gardens, Edinburgh, had the best Queen Pine Apple. For any other variety, Mr. McIntyre, The Glen Gardens, Innerleithen, had the first place. Mr. McIndoe was very successful with single dishes of fruit, taking first prizes for the following—viz., one Melon, green-fleshed; twelve Peaches, six Apricots, twelve Plums, Gages; twelve Pears, three varieties, grown under glass; twelve Apples, three varieties, grown under glass. Mr. A. Wilson, Auchincruive Gardens, Ayr, was first with six Peaches, twelve dessert Apples, three varieties, grown in the open air, and twelve Plums, yellow, other than Gages. Mr. Walter Weir, Aekton, Wrexham, had the best scarlet-flesh Melon. For twelve Plums, red or purple, other than Gages, the first prize went to Mr. Geo. Gallacher, Kilkerran Gardens, Maybole. Mr. Hugh McDerment, Alva House Gardens, was the first with twelve Jargonelle Pears; Mr. Robt. Strathdee, Tarbolton, had the best twenty-four Apples, grown in the open air; and Mr. W. Boswell, 13, Albert Place, Stirling, had the best twelve kitchen Apples; and Mr. S. W. Fairgrieve, Dunkeld, the best dish of fifty Cherries. Mr. James Day, Galloway House, Garlieston, staged the best twelve Pears grown in the open air.

VEGETABLES (open to all).—For twelve Tomatoes, Mr. J. McIndoe, Hutton Hall, was first; Mr. Jas. Bryson, nurseryman, Helensburgh, second; and Mr. Jas. Brown, Abercainrey, Crief, third. A most spirited competition took place for the collection of vegetables, but our western champion, Mr. Donald McBean, Craigends Gardens, Johnstone, held his own. Very notable in his grand collection were Celery, Leeks, Carrots, and Beet. Mr. W. J. Low, Viewforth Gardens, Stirling, was a good second; his Onions were particularly fine, so was his Cauliflower and French Beans. Mr. Thos. Hogg, Aitkenhead Gardens, was third.

MISCELLANEOUS EXHIBITS.—A very grand display was made by nurserymen of cut flowers and vegetables of their own strains. Messrs. Dobbie & Co. of Rothesay had a large collection, the African and French Marigolds being large, of fine quality, and very highly commended. Messrs. Jas. Cocker & Sons, Aberdeen, had a magnificent collection of Roses and herbaceous cut flowers, neatly set up and all named, well deserving the highest commendation. Mr. M. Campbell, nurseryman, Blantyre, had a splendid display of Dahlias, Pansies, Begonias, and Carnations, the collection being very highly commended. Mr. Alexander Lister, Rothesay, was very highly commended for a choice collection of Pansies, a seedling named Robt. Craw receiving a first-class certificate; it has had four previous to this during the season. Pentstemons were particularly fine in this exhibit, as were also Antirrhinums, Marigolds, Dahlias, Asters, and Gladioli. The same gentleman also had a number of fine Leeks named Lister's Nonesuch, a variety that has secured many first prizes. Mr. Hugh Dickson, Belfast, had a grand collection of Roses, forty-eight trusses, tastefully set up and much admired, well deserving the highest commendation. Messrs. Sam. McGredy & Sons, Portadown, had a good stand of Roses, single blooms, very highly commended. Messrs. Laing & Mather, Kelso, had a first-class certificate for Carnation R. H. Elliot. Messrs. Munro & Ferguson, Abercorn Nursery, Edinburgh, had a similar award for Matricaria inodora fl. pl. (Snowflake). Mr. Johnstone, Renfrew, had a large exhibit of horticultural baskets, teakwood and pitchpine stakes, plant tubs, &c., all well finished, very highly commended.

During the three days the Show must have been seen by over a hundred thousand persons. The Duke of Cambridge honoured it with a visit on Friday. Mr. F. Gibb Dougall, the energetic Secretary of the Society, admirably discharged the very onerous duties of managing so large an Exhibition. A member of the Executive of the International Exhibition, Mr. McLellan, the much-respected Superintendent, took a warm interest in the Show. The marquees were erected in a lovely corner of the park surrounded by shrubs and flower beds. Mr. McLellan is entitled to the thanks of the Society and its patrons for this kindness.—KELVINGROVE.

HARDY FRUIT GARDEN.

LATE PRUNING.—In many instances little or no stopping or summer pruning has been given the wall trees, while in other cases extra early stopping has been followed by a strong second growth. To leave all these shoots on the trees till the winter is simply to allow so much of the trees to be wasted, as well as to hinder the ripening of the wood and the formation of strong fruit buds. Only those shoots required for furnishing unoccupied wall space should be reserved and the rest be spurred back to within three or four joints of their starting point, deferring the final pruning till after the foliage has fallen. Closely pruned even at this late date, there is a tendency in the case of healthy trees to either break afresh or else to form wood buds rather than fruit buds. This applies only to Pears, Plums, all Cherries other than Morellos, and Apples. All reserved or leading growths should be carefully laid in to their full length, as they can better be done now than in the winter, and besides loose branches are unsightly and may be blown off at any time. Morellos will fruit next season on the young wood formed this year, but this being of a pliable nature need not be laid in till the trees are pruned and nailed next winter.

APRICOTS.—These are very late in ripening, and only in the sunniest positions will the wood mature well. In very wet and dull seasons fixed glass copings, or a glass covering of some kind, are of good service in warding off heavy rains, and they also materially assist in forwarding both the crops and the wood. During the average summers more harm than good results from leaving a covering over the trees, but those who have not removed the glass from their copings this season will in all probability detect to an inch how far down the trees are benefited by it. That portion that has been assisted during both the growing and ripening period by the extra heat retained under the glass may be found abundantly furnished with fruit buds, while the lower half or rather more may be almost devoid of bloom. Such has been the case in former years, and, judging by the present state of the trees, will undoubtedly happen again. Where strong yet not very sappy growths can be laid in to their full length, these should be retained, and if they do fruit next season will be the means of putting new life into the trees. The finest fruit is produced on young wood, and this should, where possible, replace

the old wood with its knotted spurs. Stop all foreright shoots and those not required for furnishing wall space to a length of about 5 inches.

PEACHES AND NECTARINES.—It is very doubtful if the later varieties will ripen their fruit properly, these appearing to be very much farther out of their average period of ripening than were the earliest varieties. Hales' Early has stood out conspicuously, handsome dishes being available by the third week in August. Waterloo, Early Alexander, and Early York have also given good crops of well-coloured and fairly richly flavoured fruit, but Bellegarde, Barrington, and Grosse Mignonne are quite hard as yet. Nectarines generally are late and much disfigured by rains. Hunt's Tawny, Stanwick Elruge, and Balgowan are the best for open walls. Owing to the injury done to the young foliage by cold winds in the early part of the season the growth was much checked, and much of it cannot possibly ripen properly. It ought to be freely thinned, a few well-ripened shoots being much preferable to a greater number not well ripened in consequence of being crowded. The reserved shoots should be laid in to their full length, and in addition to getting the full benefit of the heat from the walls will also admit all the sunshine we may be favoured with to the ripening fruit.

RASPBERRIES.—These have made very strong canes this season, and many more than are needed. All the old canes ought to be cut out and the young ones freely thinned, and this will enable those retained for fruiting next season to ripen properly. Autumn-fruiting varieties are very late, and unless the bearing wood is kept well thinned the fruit will be unusually sour and watery.

FRUIT FORCING.

VINES.—*Midseason Houses.*—Vines from which the Grapes have been cleared should now be divested of their laterals down to the principal buds, which are to be retained for next year's fruiting, doing so, however, without injury to the old leaves, as upon their preservation depends the maturation of the buds, which should be plump and well ripened. Vines that have not as yet borne fruit may be treated in a similar manner, so as to secure by full exposure to light the hardening of the wood. A free circulation of air is necessary, and in the case of young Vines, or where there is the least doubt about the thorough ripening of the canes, fire heat should be employed. When the laterals have been removed the old mulching, if any, should be cleared off the borders, and a top-dressing given of turfy loam, with about a fifth of horse droppings and a sprinkling of half-inch bones, or preferably steamed crushed bones. If the roots have not penetrated the mulching remove the soil down to them, and add fresh compost. In the case of inside borders afford a moderate mulching, and allow those outside to have the benefit of October rains, and instead of adding manure to the loam mulch the surface with 3 or 4 inches of fresh horse droppings, covering with dry litter or bracken by the end of October or early November. In the case of borders only partly made a breadth of 2 feet may be added to the front, choosing a dry day for the operation, mulching with horse manure and covering as before advised. Every attention must be given to young Vines planted this spring or early summer, keeping the foliage clean, removing all laterals, and maintaining a warm well ventilated atmosphere until the canes are thoroughly ripe.

Late Houses.—The Grapes in these ought now to be fully ripe, but if not continue sharp firing, accompanied with a rather free circulation of air where there are Muscats and other late Grapes until the latter are ripe and thoroughly finished, when a gradual reduction of temperature must take place, otherwise the fruit will shrivel, a state of things that must be guarded against by not allowing the borders, especially inside, to become too dry. Outside borders will in most instances be quite moist enough, and should be covered with lights preferably, or some other means employed to throw off heavy rains.

Ripe Grapes.—Hamburghs and other descriptions of thin-skinned Grapes require frequent examination for the removal of decayed berries, damp being their greatest enemy. It should be prevented as much as possible by fire heat in the daytime, accompanied by free ventilation, allowing the apparatus to cool down before nightfall, as brisk night firing is not advisable.

Vines for Early Forcing.—There must not be any further delay in the pruning of Vines intended to ripen their fruit by the end of April or early in May. Vines in pots intended for early forcing must be pruned forthwith. Shorten them to 6 to 8 feet, and prune the side shoots closely. To prevent bleeding, dress the cuts with Thomson's styptic or patent knotting.

Figs.—Fig trees in pots which are subjected to early forcing should have the roots examined, and if it is not advisable to increase the pot room, remove a few inches of soil from the base of the ball, cutting back the roots, and give fresh fibrous loam, adding about a sixth of old mortar rubbish and a sprinkling of crushed bones, good drainage being provided. Remove the loose surface soil, and use the above compost in its stead, adding a fourth of well decomposed manure. Afford a good watering, and place the trees where they can have plenty of air, with shelter from heavy rains and frost.

Fig trees planted out should be kept drier at the roots, but avoid extreme dryness, a drier condition of the atmosphere also tending to promote the perfecting of the growths. As soon as the second crop in the latest house is all gathered the trees should be kept drier at the roots, and the house well ventilated in favourable weather. Any root-pruning or partial lifting should be done when the leaves show indications of falling.

KITCHEN GARDEN.

VEGETABLES AND THE WEATHER.—There is now every prospect of winter vegetables being in good condition, and growers ought to take advantage of the fine weather to see that their crops are in no way shaded by being grown too close or infested with weeds. Last winter vegetables suffered greatly; they were very scarce long before the spring crops were ready, and the failure of many crops may no doubt be attributed to shading and crowding in late autumn, when they should be fully exposed to the sun and air.

HARVESTING ONIONS.—All Onions should now be harvested. As a rule they are much smaller than usual this season, but this is no great fault, as small or medium-sized Onions usually keep better during the winter and into next summer than large ones. We have often divided our bulbs, storing the smaller for keeping and putting the large ones aside for immediate use. Dry the bulbs thoroughly; placing them under cover and sorting them afterwards will give employment on wet days. James's Keeping is still the best Onion for late use, and Bedfordshire Champion comes next to it, and care should be taken that these are not used before some of the earlier sorts.

PLANTING CABBAGE.—The July sown seed has produced plants that are ready for planting in permanent quarters. It is best to do this before they become crowded. We have planted some hundreds that are about 4 inches high. They appear small, but will grow very sturdy, and this is what is wanted for standing the winter and heading early in spring without bolting. Our spring Cabbages follow the summer Onions, for which the ground is well manured, and we do not manure again for the Cabbages. When the Onions are cleared off the surface is hoed and raked and the Cabbages planted without any further preparation. Drills about 3 inches deep are opened and the plants inserted in them at a distance of about 18 inches apart each way. The soil being very firm the plants make much more robust growth than if planted in recently manured loose ground. We draw the largest of the plants from the seed beds and plant them while the smaller ones are allowed to remain for successional planting.

EARTHING UP CELERY.—The main winter crop requires earthing up about this time. Celery takes upwards of a month to blanch, and sometimes more. Remove all small superfluous side leaves, tie the others together near the top, then apply the earth. Soil falling into the centre of the plants is ruinous to them. Break the soil on the ridges well, push it towards the plants with the spade, then place it close round each plant with the hands. This takes a little longer than pushing it in with the spade, but is all the better for the plants.

YOUNG CAULIFLOWER PLANTS.—Those intended to keep through the winter for planting out in spring for the first crop are nearly as large as the Cabbages. They are too close to remain in the seed bed, and the sooner they are transplanted the better. They must have a little protection in favourable localities, and a good deal in cold districts. It is, therefore, best to plant them in a frame or in a position where a frame can be put over them when severe weather comes. The soil in which they are planted should be moderately rich and very firm, and if the plants are inserted 3 or 4 inches apart they will have space to grow. If in frames keep them as close to the glass as possible, as if deep down they will be drawn, and many of them fail to produce proper heads in spring. We have wintered plants very successfully under handlights. They were transplanted in the squares about this time, but not covered until much later, as it is very important that the plants be kept hardy in autumn to bear the winter well.

LIFTING AND STORING POTATOES.—The fine weather has induced us to dig many Potatoes during the last week. We have lifted and stored several tons, and although below the average in size, they are not so badly diseased as we expected to find them. In light and medium soil they are remarkably free from disease, but in heavy soil at least half the crop is lost. The soil, however, is now very dry, and it falls away from the tubers so freely that there is no difficulty in seeing which are diseased and which are sound, and great care should be taken that the two are separated before storing. They must be quite dry, but if left in the sun too long they will be green and bitter. We store them in a dark place to which a little air is admitted.

PLANT HOUSES.

Medinilla magnifica.—Where this plant has been grown in the stove up to the present time, it should be removed to an intermediate temperature at once. The object is to prevent it starting again into growth. It should be fully exposed to the sun, and if possible a drier atmosphere maintained for it. Careful watering is necessary. This plant is very subject to thrips, which must be destroyed by a solution of tobacco water.

Softwooded Ericas.—With the present favourable change in the weather every attention must be paid to the watering of these plants. Be careful that they do not suffer by an insufficient supply of water at their roots, or early kinds, such as autumnalis, hyemalis, and others are certain to be blind. From the time the flowers are first formed until they show colour is the most critical period in the growth of Ericas. A check to the plants, whether by becoming dry or from any other cause, will bring about failure. The syringe may be freely used early in the afternoon of bright days. It will not be needed in the morning, for the lower night temperature to which they will be subjected while outside this month will insure them being heavily laden with dew in the morning. Water Epacris with the same care, and fully expose them to full sunshine, for upon the ripened condition of their wood depends their flowering well.

Azaleas.—Early varieties generally ripen, although the plants may have been grown under Vines and Peach trees. The plants, however, will be greatly benefited if they are stood out for two or three weeks. Expose later varieties to full sunshine, and let them have abundance of air. They will ripen rapidly with sun during the day, followed by a low night temperature consequent upon leaving the ventilators open. Be careful they do not become dry, and syringe those under glass liberally twice daily in bright weather.

Camellias.—Be careful with those that are only just forming their flower buds. Maintain a drier atmosphere, and give no more water than is really necessary until it is certain the buds are swelling, when the plants may be treated more liberally in respect to moisture. The object is to prevent their starting into second growth. Earlier plants should be swelling their flower buds rapidly. These should have weak stimulants occasionally, and abundance of water at their roots. The syringe may also be used freely twice on fine days.

French and Fancy Pelargoniums.—All the early plants of these should, if not already done, be placed into 5-inch pots, their flowering size, using good loam, one-seventh of manure, and sand pressed firmly into the pots. They must not be over-watered or they will make growth too rapidly. Keep them on the dry side, give abundance of air, and the growth will be of the sturdiest description. Cuttings that were rooted together in pots and pans place singly in 2½-inch pots in the same compost, and grow them under the same conditions. Old plants shake out and place in smaller pots. They may be kept close for ten days or a fortnight afterwards, and then given the treatment advised above.

Calceolarias.—Transplant all that need it into pans and boxes before the seedlings become crowded. Earlier ones may be transferred from boxes into 3-inch pots. The earliest of all if ready may be placed in 5-inch pots, in which they will do very well until the close of the year, when they can be again shifted if large plants are needed. Late sown plants kept through the summer in a shady position have now four or five strong growths that have issued from the base. Remove a few of the lowest leaves from such, pot the plants deeply, and they will quickly root from the stems, then with good cultivation produce heads of bloom 3 feet in diameter.

Bulbs.—Pot and box quantities of Hyacinths, Narcissus, and Tulips at intervals of three weeks or a month until the end of October. It is not advisable to delay the potting of Hyacinths after the middle of that month; but Narcissus Grand Monarque and double Tulips may be retarded until the middle of the next month. These will yield flowers for cutting until June if they are kept in a frame with a northern aspect after they are removed from the plunging material and then placed outside where the sun will not reach them.

THE BEE-KEEPER.

THE CLOSING SEASON.

At last this abnormal and most disappointing season is nearing its end. We cannot in any way lament its dying moments. We rather rejoice that at last there is an end to our hopes instead of the continued and exasperating attempt to hope against hope for a change for better weather in order that a little surplus might be secured. After all, we do not think that there is any cause for the lugubrious comments which have appeared in some of the daily papers, pointing to a serious diminution in the number of stocks which will be found in health in the spring of next year. We are inclined to think that if proper attention is given to the wants of the apiary no great increase in mortality will be experienced during the next six months; but if ever there was a year when care was necessary it is in the present autumn, when failure to give the necessary attention must end in absolute disaster. "A Lanarkshire Bee-keeper" comments upon the great difficulty which has been experienced in this most untoward season in getting young queens fertilised, and in doing so he has struck a vein which we had purposed working in the present article, but which may now be passed over with the remark that one of the greatest dangers with which we shall have to contend in March and April will probably be due to the giving out of the powers of worn-out queens. Now to a great extent even this danger may be averted by those bee-keepers who keep a record of the age of their queens, and who are also able by an intelligent use of their powers of observation to perceive which queens are the more likely to be in health and power next spring. Our efforts must be concentrated upon the preservation of those stocks which possess valuable queens, and it would be also wise to save what would in other years be considered as practically worn-

out mothers, in order that if any accident should happen to the younger queens at the head of our best stocks we may have a successor which may be able to perform the functions of a queen until some of our foremost colonies are strong enough to be devoted to queen-rearing.

There is another point upon which it may be well to touch. "A Hallamshire Bee-keeper," referring to the article on queen substitution in a past issue, comments upon the omission to furnish instructions for introducing queens. This was an intentional and premeditated omission, and for the following reason. In the spring of the present year we discussed at some length the best means of introducing queens and gave some instructions accordingly. Upon these instructions appearing a most interesting discussion sprang up, and it was our intention during the past summer to have tested once more the several methods and then to have given the result of our further experience. This has been impossible, for the simple reason that the weather has been of a kind to warn even the most careless bee-keeper that the fewer the manipulations the better the chance for the stocks, and another reason has been the great difficulty of obtaining fertile queens and their more than ordinary value when they had been secured. It seemed, then, a wiser course to allow those who have given the question of "queen introduction" an amount of attention far greater than it has been in our power to do, to give the necessary instructions, than to instruct where we should ourselves like to have some further experience in view of the opinions expressed, when we did venture to offer an opinion which was based upon considerable practical experience in the apiary. For our own part we cannot conceive that a bee-keeper who really makes an earnest attempt can fail to introduce a queen provided he makes use of a "safe method," and this we should certainly advise every bee-keeper to do rather than run any risk with valuable queens.

It is possible that "A Hallamshire Bee-keeper" failed to convey his exact meaning in the article to which we made allusion a few weeks ago, and to our comments on which he refers in the last week's issue, and we shall be glad if he will state more precisely what he did mean his readers to infer, in order that no suspicion of making fun of him may again be allowed to drop from our pen. Of one thing we can assure him, and that is, that few know more of the practical difficulties with which inventors occasionally meet in the endeavour to reap the result of their ingenuity than we do ourselves—in one capacity or another—although we are inclined to think that some people attach a greater importance than it deserves to the piracy of inventions which is to some extent rife amongst us. Five shillings a piece for sections is a decidedly tall price, but if a bee-keeper can obtain it, why, he had better accept it. It is, however, in very few cases feasible to obtain so gigantic a price for a commodity which, although it may be scarce, is not by any means a necessity. Our sections are all sold, and at a price less than half that mentioned by "A Hallamshire Bee-keeper," and if we could rescind the sale to-day we should prefer to let things remain as they are, feeling satisfied that the purchaser has lost nothing by his purchase, and that we have lost nothing by the sale.—FELIX.

TRADE CATALOGUES RECEIVED.

- MM. Ketten frères, Rosieristes, Luxembourg.—*Catalogue of Roses*.
- Robert Veitch & Sons, Exeter.—*Catalogue of Dutch Bulbs and other Flower Roots*.
- Thomas S. Ware, Tottenham.—*A B C Bulb Guide*.
- J. Linden (International Horticultural Company), Parc Leopold, Brussels.—*Catalogue of Orchids and New General Plants*.
- Benjamin Soddy, 243, Watworth Road, London.—*Catalogue of Hyacinths and other Dutch Bulbs*.
- G. H. Krelage & Son, Haarlem, Holland.—*Catalogue of Dutch and other Flowering Bulbs and Plants*.
- W. Piercy, 89, West Road, Forest Hill, London, E.C.—*Descriptive List of Early Chrysanthemums*.
- C. Kerkvoorde, Wetteren, Belgium.—*Catalogue of Roses, Trees, and Flowers*.
- Wm. Rumsey, Waltham Cross, N.—*Catalogue of Roses*.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Recruiting Roses (Herts).—Mr. Bardney is not the man to forget his promise, and the notes you will see from him in another column were in type several days before you penned your letter.

Notes (G. H., Lancashire).—We are obliged by your communication, but the subject has been fully dealt with. We shall be glad to publish notes on the Potato crop, with the best methods of procedure where disease exists, and of storing the tubers.

White Begonias (T. Smith).—The two flowers of single white Tuberos Begonias you send are very good indeed. One is $5\frac{1}{2}$ inches in diameter, of good substance; the other $3\frac{1}{2}$ inches in diameter, stout in texture, and as circular as any Begonia flower we have seen. They are both worth preserving.

Variegated Sycamore (John Carter).—The leaves are distinctly and effectively variegated, some of them being from half to two-thirds creamy white, while a few only contain small specks of green. If the tree grows freely, and the variegation is constant, it would be decidedly ornamental in parks and plantations. We suspect, however, that few persons are better able to judge of its value and distinctness than yourself.

Greenhouse Plants Failing (S. Williams).—If no deleterious fumes find entrance to the greenhouse of your friend, the cause of the failure must be attributed to errors in ventilation or faults in cultivation; but without knowing the methods pursued it is obviously impossible for us to indicate, with any precision, the source of the evil. Too late morning ventilation is the cause of many failures in amateurs' greenhouses.

Floriferous Gladiolus (W. B.).—You are not very likely to see spikes like the one you have sent exhibited at the leading shows, as growers for exhibition would consider such defective. There is a slight fasciation of the stem, causing the flowers to appear almost in a bunch at the top of it. We have seen many similar, and though such spikes arrest attention though differing from the type, we can hold out no hope of your making a fortune by your seedling.

Stripping the Leaves off Pelargonium Cuttings (A Youngster).—There is reason in everything. To strip off all the leaves is a bad plan, and is therefore not practised by any good gardeners; at least, all we know worthy of the name only strip off the leaves from that part of the cutting to the extent of its insertion in the soil. Those leaves being the oldest are of least value from a rooting point of view, being more exhaustive of than contributing to the vigour of the cutting, and soon become sere if retained, hence are removed; but leaves on cuttings above the soil undoubtedly facilitate the rooting process.

Charitable Fund (T. S.).—We have considered your proposition, which is good in itself, and does credit to you as a sympathiser with distress. Much as we could wish all widows and orphans of gardeners provided for, this is at present impracticable, and with wider support accorded to existing institutions we are convinced more good can be done than by the project which you are quite justified in placing before us. The contributions to the Gardeners' Orphan Fund are as low as could be framed, and widows benefit as much as orphans do by this institution. These are also eligible for election as pensioners of the Gardeners' Royal Benevolent Institution.

Cuttings and Plants Damping (G. Y.).—Zonal Pelargonium cuttings are unusually succulent this year, and only the most exposed, firm-looking, short-jointed shoots should be chosen for cuttings; and these after being made may be left for the wounds to dry before insertion. Very gritty soil should be used, consisting chiefly of sandy loam with a free admixture of sifted lime rubbish and crushed charcoal. The soil being moist water will not be required for a few days, and when needed sufficient ought to be given to pass through the soil, light and frequent sprinklings being ruinous. If the earth is moist on the surface

and dry below the cuttings are bound to decay. Abundance of light and air, with protection from rains, are essential at this season of the year. You should have given some particulars about the old plants, the position they occupy, and the treatment accorded them. You do not even say whether they are in pots or not. We are quite ready to give what information we can on your making the case clear that is at present obscure.

Worm-like Insects in Soil (C. O. S.).—These are small immature specimens of a species of centipede, probably *Geophilus subterraneus*. This and kindred species have occasioned much trouble to gardeners for some years past, their insidious habits making them difficult to extirpate. Free watering with lime water (clear) is good, as you suggest, and if the insects are detected on beds, the application during spring of lime, soot, and wood ashes, mixed in equal proportions. Some of our friends have lately tried petroleum, in the proportion of 1 oz. to a gallon of water, well agitating before application. A number of these centipedes may be trapped, at any stage of their growth, by burying in the earth slices of Potato and Carrot wrapped in a little hay or moss. A decoction of hellebore made by mixing 2 ozs. of the powder in boiling water to the consistency of cream, then stirring this in a gallon of water, is good. It is an excellent plan to bake infested soil for potting purposes, moistening previous to use. We only know of one garden in which this practice has failed, but there may be more.

The Oldest Apple (Scutus).—No doubt as you say there are differences of opinion on the subject. What "Dr. Hogg thinks about it" is conveyed in a note in his "Fruit Manual" in the following words:—"This is, I believe, the oldest existing English Apple on record. It is noticed as being cultivated in Norfolk as early as the year 1200,—what evidence against Mr. Knight's theory! In Blomfield's 'History of Norfolk' there is mention of a tenure in that county by petty serjeanty, and the payment of 200 Pearmaines, and four hogsheads of cider of Pearmaines into the Exchequer, at the Feast of St. Michael, yearly. It is the original of all the Pearmaines, a name now applied to a great variety of Apples. Much doubt has existed as to the origin of this word. The early forms in which it was written were Pearemaine and Pearemaine. In some early historical works of the same period I have seen Charlemagne written Charlemaine, the last portion of the word having the same termination as Pearemaine. Now, Charlemagne being derived from Carolus magnus there is every probability that Pearemaine is derived from *Pyrus magnus*. The signification, therefore, of Pearmain is the Great Pear Apple, in allusion, no doubt, to the varieties known by that name, bearing a resemblance to the form of a Pear."

Good Border Carnations (A Sixteen-years Subscriber).—The following are selected as of "good constitution and did not split their pods" this year in a collection of several thousands of plants in all the leading varieties grown by Mr. John Forbes at Dover House, Rotherhampton. Growers of these flowers are at liberty to supplement the list with other varieties they have found of "good constitution and do not split their pods." Here is the Dover House selection with the colours of the flowers. *White*: W. P. Milner, Virgo, Gloire de Nancy, Ossian, and Miss M. North. *Scarlet*: Brigadier and Illuminator. *Purple*: Walter Ware, Evelyn, Auctioneer, and Royal Purple. *Pink*: Gertrude Tegnier and Raby. *Rose*: Queen of the Roses and John Barnet. *Yellow*: Florence and King of the Yellows. *Purple Flakes*: Miss Mills, Ajax, James Douglas, and Squire Trew. *Scarlet Flakes*: Flirt and Dan Godfrey. *Rose Flakes*: Lovely Ann, Rose of Stapleton, and James Merryweather. *Scarlet Bizarres*: True Briton, Prince Albert, William Spoor, and Lord Wolverton. *Crimson Bizarres*: J. D. Hextall and Duke of Bedford. *Pink and Purple Bizarres*: James Taylor and Sarah Payne. *Fancy Varieties*: Lightbody's Seelling, Grandiflora, Sir B. Seymour, Goldfinder, and Alderman.

Arranging Conservatory (Novice).—The walls will look very tame covered with Ivy. We suggest that the most conspicuous be covered with ornamental rockwork to some little height from the floor, and above that have rockwork pockets for Ferns, ornamental leaved Begonias, Tradescantias, and similar plants, and cover the smooth portions of the walls with *Ficus repens* and var. *minima*. It is very close growing, forming a capital background to the Ferns, &c., and is better indoors than Ivy. Vines would not succeed in such house, nor are Roses suitable unless they are trained well up to the glass, and have plenty of light. We should have a border along the front inside, and plant *Lapageria rosea* and *L. alba*. They are charming when seen together, and would grow admirably in such position, training them up the front and over the roof from 6 to 9 inches from the glass. Camellias would do well, and Oranges may be grown in pots; but it would be best to rely chiefly on Palms and other foliage plants, such as *Indiarubber*, *Aspidistra lurida variegata*, *Dracena congesta*, *D. australis*, *Aralia Sieboldi* and var. *variegata*, *Phormium Veitchi*, and *P. Colensoi*. For hanging baskets you could not have anything better than Ferns, such as *Nephrolepis Bausei*, *Davallia fijiensis major*, *D. Mariesi*, and *Platy-cerium alcornae majus*.

Apricots under Glass (J. S.).—Where a wall 10 to 12 feet high exists with a south, south-west, or south-east aspect, it may be covered with a case of about 4 feet 6 inches in width, having a boarded front 18 inches high, with a board 9 inches wide hinged at the top and opening outwards the whole length for front ventilation. The top lights may be 2 feet 6 inches wide, and fixed at an angle or incline of two-thirds the width of the lights, which should be made to open the whole length. The slope of the front lights will be determined by the front and top

lights, and those may be fixed or not made to open, but they should be moveable, so as to admit of their being removed in autumn to ensure the trees rest until it is necessary to replace the sashes in the spring. The roof should be wired 6 to 8 inches from the glass, not more distantly than 4½ inches. The trees should be planted about 9 inches from the front inside, dwarf trained trees disposed 15 feet apart. In the absence of a wall a span-roofed house would be the most suitable, ends north and south, and may be made similar to that described for covering a wall: in fact, two lean-to's joined together with trees on both sides and a pathway up the centre. The chief requirements for Apricot culture under glass are a calcareous firm soil, efficient drainage, mulching and feeding, with cool treatment—i.e., abundant ventilation, especially in the early stages and over the stoning period. If heat is used it should only be to the extent of securing the safety of the blossom and young fruit from spring frosts.

Vines Unsatisfactory (W. C.).—The leaves are thin in texture, spotted, and very pale in colour, which is chiefly caused by insufficient, injudicious, and inattention to early ventilation. Their present condition is not due to a cold close border, but to error in the treatment of the Vines generally. Your taking out the walk deeper than the border will help the drainage, which, however, seems unnecessary, as there is no "standing water." It seems you have made a border upon the site of, the old without removing the old Vine, therefore the concrete is over the old Vine roots, and it is practically sealed against nutrition. The young Vines, it seems, are not doing well, but if the border is properly made and the treatment good they ought to flourish. We are sorry to say we do not understand what it is you propose to do further with the border. If the border is formed as you describe—viz., "concreted, the bottom drained with plenty of stones and turves placed on them, then filled in with a mixture of turf, garden soil, stones, charcoal, and a little stable manure," it should grow good Grapes if these are drained with proper fall and outlet for the escape of superfluous water. If there is no provision for this how is a concreted border to be other than sodden? The disaster to the old Vine is mainly due to making the concreted border over its roots. Unless you can induce it to emit roots from the part of the stem above the concrete, it will not do any good. Had it been left alone and a departure made in pruning, and care taken to preserve the foliage from falling a prey to red spider, it would in all probability have gone on fruiting. It only needed more liberal treatment to insure a better result. In answer to your queries, first, "Would the foliage being spoiled cripple or weaken the Vines and so cause their not fruiting?" we answer, Yes; and second, as to what you have done and what you propose "to get fruit next season," so far as we can understand the case, we cannot assure you of success.

Ripe Nectarines (Idem).—Nectarines this year are much given to shrink or shrivel at the apex when ripening. This is probably due to the prolonged dull and wet weather which prevailed during their swelling and the bright weather following causing extreme evaporation from the fruit. Some Nectarines, though ripe and even shrivelled at the apex, are not ripe at the base or stalk. But why leave the fruit on the trees until it falls? When it is ripe, even before dead ripe, it should be carefully gathered.

Young Gardeners and the Journal (C. D.).—Your experience is similar to that of many other young gardeners who have been enabled to surmount difficulties through following the instructions given in our columns. There is scarcely a young gardener who enters on a charge who has not something to learn. Requirements may be different from those to which he has been accustomed, though he may be an able man all the same; and we are ready to help all who need hints for their guidance on their wants and means of meeting them being made clear. Like yourself, many readers find what they need without special inquiry; but it is a great mistake for any person who needs assistance on special matters to hesitate in asking for it, as by waiting for it to appear in the ordinary way he may wait too long. It is not in the slightest degree derogatory on the part of any person to seek for information that he needs, no matter how apparently simple the subject may be. Some of the greatest men in every profession or vocation are the greatest questioners. It is perhaps that habit which has helped to make them what they are, coupled with another of enormous importance, of sifting the chaff from the grain in the replies, retaining the latter only, casting the former to the winds. It is, we are glad to know, the custom of many young gardeners to "take the Journal" when they enter on a charge, and some of the most experienced gardeners in the kingdom, when they desire to see their young men prosper, advise them to read and study all they can, but not to omit these pages. You have no occasion whatever to apologise for the matter and style of your letter. It is well and correctly written. You must have been diligent in the laudable work of self-education, and with very little practice you may become a teacher of others through the medium to which you so frankly acknowledge your indebtedness. We are glad to receive your letter, and though you did not ask us to suppress your name and address, we do so, since you were, of necessity, unaware of the nature of the observations elicited. If you do not object we may perhaps publish your letter on a future occasion with your name, but have no desire to do so against your inclinations.

Dendrobiums and Cattleyas (J. P.).—Some Dendrobiums are deciduous and others evergreen. The former generally have their foliage on each side of the pseudo-bulbs, although some of the evergreen kinds are also of this mode of growth. Of the latter *D. nobile*

and its varieties, as well as *moschatum*, may be taken as examples. In both cases these lose their foliage the second year, and when thoroughly ripened the first season the foliage gradually withers. Of such as *Wardianum*, *crassinode*, *Devonianum*, and *heterocarpum*, the latter flowers only on growths that are two years old, while the others flower on well ripened growths of the current year. The evergreen kinds generally have a few thick fleshy leaves on the top of their pseudo-bulbs. If you observe carefully you will see the young growths in many cases lengthen before they form roots to any extent, and if the old pseudo-bulbs are removed they are certain after the first year to decrease in size and strength. The young growths draw from the older the support they need until they have sufficient roots to support themselves. Several strong growers, such as *Wardianum*, practically use up the old growths in one year, and may with safety be removed during the resting period, or just before the plants come into flower. You will act wisely in leaving them attached to the plants until they shrivel naturally. Very frequently the evergreen varieties produce back growths, and thus increase the size of the plants. The growths last upon them for several years. The deciduous will bear during the resting period a much lower temperature than many of the evergreen varieties. The growths of *Cattleyas* must not be removed unless you wish to destroy the plants. The pseudo-bulbs and foliage will last upon them for several years. Healthy plants invariably produce growths from the back pseudo-bulbs. If they do not do this the rhizome may be partially cut through after flowering, which will induce the back eyes to come forward more quickly. When growths from these have well started, and they have rooted sufficiently to support themselves, the rhizomes may be severed. This is not absolutely necessary, for once the buds are produced they will annually increase in size and strength under good culture.

Wood-burrowing Caterpillar (L.).—Your Weeping Ash tree is infested with the caterpillar of the Wood Leopard moth (*Zeuzera aesculi*), but it attacks other trees more freely than the Chestnut (*Aesculus*), the Ash being one of them. As is recorded in Miss Ormerod's Manual the eggs are laid during July, or later in the summer, in crevices of the bark, and on the branches as well as the trunk of the trees; these eggs are oval and salmon coloured, and as many as 300 have been seen laid by one moth. The caterpillars, which soon hatch, feed at first in the bark, but not long afterwards they make their way into the live wood, where they bore galleries rather wider than themselves, and as much as a foot in length. When full grown they are about 1½ inch long, whitish or pale yellow, with a black horny plate on the segment behind the head and another above the tail; the other segments are spotted with black, and the head is black or has two black spots. They feed wholly or at intervals until May or June (statements are made that they live for two years), and, when full-fed, they spin a web, or form a case of wood dust, in which they change to an ochreous-brown, long, cylindrical chrysalis. This web is usually woven just inside the bark, near the entrance of the boring, so that when the time for development is come the chrysalis forces itself through the opening, and, by means of the fine prickles with which it is furnished along the back, it is held firmly in the web whilst the moth frees itself, and leaves the empty case projecting from the tree. The moth is large and handsome, with a white head; the wings are somewhat transparent, and are white with black spots, the spots being darkest on the fore wings; which also have yellow veins. The body between the wings is white spotted with black, and the abdomen grey, or grey banded with black. It is stated that the female moths appear somewhat later than the male, and may be found until the end of August. It is difficult and tedious to destroy the caterpillars. They may be destroyed by drawing them out of their burrows with hooked wires, or by running a strong wire into the hole, and thus crushing the caterpillar within to death. If the wire, when withdrawn, is found to have wet whitish matter on it, such as would result from having crushed the larva, or again, if gnawed wood should have been passed out of the burrow up to the time of the operation and no more appear afterwards, it may be supposed the creature is killed; otherwise the operation should be repeated. Syringing is also of service in getting rid of these caterpillars. For this purpose with a sharp-pointed nozzle fitted to the syringe, the hole may be filled with strong tobacco water and softsoap. The fumes of sulphur blown into the holes are also effective in destroying the caterpillars.

Names of Plants.—We only undertake to name species of plants not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*T. S.*)—1, *Adiantum æmulum*. 2, *Adiantum Capillus-Veneris* var. *incisum*. (*W. & J. B.*)—*Tilia platyphyllos laciniata*, a cut-leaved form of the Lime. (*H. H. C.*)—Several of the perennial *Campanulas* do not reproduce themselves true from seed. The varieties you send have probably no recognised names, and the specimens are quite insufficient for determining the point. We can only say, judging by the withering leaves alone, for there is not one flower; that No. 1 resembles *C. urticifolia*, and No. 2 an inferior form of *C. turbinata*, of which seedlings are of most uncertain heights. You had, however, better regard them both as nondescripts. (*W. Bucks.*)—The name of the *Epidendrum* has been confirmed, but the other flower did not afford sufficient material for determination. (*W. N. C.*)—1, *Centaurea suaveolens*; 2, *Atriplex hortensis*; 3, *Colutea arborescens*.

COVENT GARDEN MARKET.—SEPTEMBER 19TH.

MARKET quiet, with little alteration. Plums lower.

miles of the south coast; subsequently we have had to go north as far as the Highlands of Scotland. We have lost no opportunity in those journeys of seeing all we could of the crops and farming practice in every district we visited, and have, on the whole, just reason for saying that British farming is anything but a failing industry yet.

Perhaps the finest example of corn-growing in the world, certainly the best we have ever seen, is that which the Fen districts of North Cambridge and South Lincoln now afford. We are well within bounds in applying the term magnificent to the crops which we saw there ready for the reaper in the first week of the present month. In the fields where the corn was being cut the surface was crowded with sheaves. The yield of straw there will far exceed the average, and that of the corn too must be high. Well, since then we have been able in East Anglia to build nearly a score of huge Wheat stacks, and doubt not that the fenmen have missed no chance of doing all they could to save their bountiful crop of corn.

If farmers below the Trent cry out about a late season and a disastrous year, what may we expect to hear from Yorkshire, Durham, Northumberland, and the Lothians? For there many of the corn crops are still green, and farmers between 54° and 56° of latitude certainly need stout hearts to face the difficulties arising from such an adverse season. In Yorkshire and Durham we regret to see so much needless sub-division of farms, and strongly recommend estate agents there to do all they can to sweep away useless interior divisions. We know that sweeping reforms involving a heavy outlay are impracticable in districts where rents have fallen to such a nominal sum as has happened in some parts of Yorkshire. But no contrast can possibly be greater than that of many such farms and those which we saw north of the Tweed. "Why!" said an enthusiastic friend who was travelling with us, "every field is clean as a garden." He was right. However much hard times may press upon Scottish farmers it has caused no falling off in that high and finished system of cultivation for which they are deservedly famous. The land is kept free of weeds, and the whole of its fertility is absorbed by the legitimate crop. Some Barley and Wheat—most of the latter—may be seen in the Lothians, but it is Oats and root crops that are to be seen there in perfection, and it was undoubtedly a lively recollection of such crops that induced a certain canny Scotchman to advise farmers in East Anglia to substitute the culture of Oats for Wheat. His advice was untrustworthy, as he was quickly made to understand, but as the French say, "he had reason."

The Wheat, so far, has been got together without any serious amount of damage from sprouting, but very much of the grain is soft, and, though the stacks are built long and narrow, it will be some time before the grain is in the best order for threshing. Yet it will be advisable to wait, if any reliance is to be placed in published reports of the Wheat crop, for we are told the estimated production of Wheat in Europe falls short of that of last year by 21,000,000 quarters. Adding the estimated deficiency in the other principal Wheat-growing countries of the world, the produce of the present year comes out at 23,000,000 quarters less than that of last year. To all who can possibly afford to wait, every report or calculation we have seen clearly says, Do so. If you only grow four quarters an acre, waiting may mean 40s. an acre more to you from the Wheat, and that sum, in these critical times, may mark the difference between success and failure. To all farmers we say, Continue to give all possible care to the selection of pure seed of the best sorts, get your land clean and dry, store it with fertility, keep down weeds, and do all that is possible to bring and keep the land in the highest possible state of cultivation.

WORK ON THE HOME FARM.

Harvest work is still in hand, but fine settled weather has at length enabled us to push briskly on with it, and there is now a fair prospect of a speedy ending. Barley, though the grain is thick-skinned and much discoloured, is being carted quite ready for threshing, and the strong growth of Clover mingled with the straw will prove such excellent

HARVEST PROSPECTS.

REPORTS more or less positive, and certainly more or less speculative, as to harvest prospects are being published very frequently both in the daily papers and in the organs of the agricultural Press. Most of them point to a probable rise in the price of corn, and elaborate tables are given again and again in the attempts to prove certain conclusions by the aid of figures. Meanwhile farmers keep plodding on under difficulties which seem to increase rather than diminish under the depressing influence of cloudy skies and a wet summer, and corn stacks are springing up slowly very much in accordance with the prevalence of those "local showers" which have been predicted day after day in the weather forecasts; but writing on the third day of fine bright weather we feel hopeful that a bountiful corn crop may be saved in fair condition, and that after all the harvest of 1888 may not prove a failure.

Just at the beginning of harvest business took us within a few

fodder that some farmers assert it will be as valuable as the corn. Spring Oats ripen slowly and badly, corn so ripe as to be easily shaken out of the ear being visible among much that is still green and unripe. Winter Oats, on the contrary, were carted comparatively early, threshed, and the straw cut into chaff, so that we have ample store of sound wholesome food for the horses at harvest work. Green food alone is insufficient for them, for we have hilly fields where four horses are required for each waggonload of corn, and it is highly important that horses be kept in high condition now, as ploughing and Wheat-sowing must follow harvest work closely. Two or three days of bright sunshine and wind have hardened Wheat so much that the threshing machines are at work on it, and fair samples are being offered at market. This early corn-threshing is an outcome of dire necessity, and it has already caused a downward tendency in the price of Wheat. Farmers are so hard pressed for money that they are in many an instance obliged to realise what they can from farm produce as soon as possible. To home farmers who have to maintain a supply of flour from home-grown Wheat, we advise caution about threshing prematurely. Where Wheat was carted as it became dry between showers, the grain cannot be in a suitable condition for grinding for some months, and it is better to leave a certain quantity exposed long enough to ensure condition, even with some risk of sprouting. A common scarcity of straw has led to a little early Wheat-threshing, and the grain will be turned to account for sowing, otherwise it is as well to store enough sheaves in a barn to afford a supply of seed, and so avoid having to pull the stacks about for seed corn.

MAKING ENSILAGE.

WE have received from Messrs. Eyre & Spottiswoode a pamphlet of fifty pages, published by them under the direction of the Ensilage Society. It is entitled a "Practical Guide for Making Ensilage," and appears to contain much information on the subject treated: also gives evidence of successful results. An extract from the first three pages will show the character of the work.

There is scarcely anything which grows on the farm which may not be made into ensilage. From Maize to Mangold tops, from Beans to Beetroot, from Tares to Thistles—the silo or the silage stack will receive all alike, and preserve as serviceable fodder. This, however, is not to say that the resultant fodder from these various crops is all alike. It differs necessarily as much as the crops differ. That which is put in comes out. If it be successfully ensiled it comes out but little different, either chemically or apparently, to what it went in. It follows, therefore, that the more valuable the crop, the more valuable the silage made from it.

All the graminaceous, leguminous, and cereal plants commonly cultivated are suitable for ensilage, and all have been successfully dealt with. The legumes have sometimes appeared to be a little more difficult to deal with than grasses or grain, but with ordinary care they may be made into valuable silage. In the return on ensilage made by the Agricultural Department of the Privy Council in 1885, it was remarked—"Meadow Grass, Clover, Trifolium, and aftermath appear to have been generally preferred for ensilage crops, but coarse berbage of all kinds, however uneatable it would be if made into hay, has been used to form ensilage. Oats, green Barley, Wheat, Maize, Buckwheat, Sainfoin, Rye, and other artificial Grasses, Vetches, Lucerne, Hop-bine, Mangold, and Turnip-tops, Peas, and Beans, with mowings of rough grass from plantations and orchards, hedge sides and ditches, together with Nettles, Sedges, and Rushes, have all been more or less successfully made into ensilage, and in that palatable form have been taken eagerly by stock." This utilisation of waste substances is in fact a salient feature of the ensilage system. In some circumstances it becomes an important part of farm economy. Fern, for instance, especially in Scotland, if it be cut sufficiently early, has been made into serviceable fodder in this way, and the same may be said of Hop-bine in the south.

The proper time of cutting the crops intended for ensilage is a highly important consideration. The object being to obtain a succulent food the plant should be cut not only in a living state, but when it contains all its natural moisture. To obtain this it is essential that the crop should not be permitted to get over-ripe when intended for ensilage. The following may be reckoned as the best stages at which to cut the crops named:—

Grasses and Clovers—as soon as they come into flower.

Tares or Vetches—when the corn begins to form in the pod.

Rye, Oats, and other cereals—when the corn is bursting into ear.

Before cutting the crop the preliminary question as to placing it in a silo or a stack must be settled. This must mainly be left to individual choice as influenced by local circumstances. Where a silo is already to hand we should unhesitatingly say—Fill it. Where no preparations have been made, the respective advantages will have to be weighed. On the side of the silo there is, in the first place, a minimum of waste. The provision also is a permanent one, and the silo, whatever its form, may be available for other uses when not occupied by ensilage. Forming part of the farm buildings it will probably be conveniently situated for feeding the ensilage to the stock. On the side of the stack there is, foremost, the question of cost. Under special conditions, and especially by the conversion of a barn or other building, a silo may be inexpensively obtained; but, as a rule, its first cost, whether it be built or excavated, is considerable. The stack avoids this outlay, though at the expense of some waste on its exposed sides. Another point in favour of the stack is that it may be erected on the field where the

crop grew, and thus save the labour of carting green stuff any long distance—a very appreciable consideration. A point which may have weight with some is that "sweet" ensilage is more easily made in a stack than in a silo.

Supposing a silo is used it will be well to consider whether the stuff may not be chaffed with advantage before being pitted. Some of the most experienced ensilage makers consider that the advantage of chaffing far outweighs its cost. The stuff lies closer together in the silo, and is thus more easily compressed, while it is also very convenient in a chaffed state for feeding to stock and mixing with other foods. Of course, in the case of a stack, chaffing is impossible.

Supposing a stack to be decided upon, the farmer's first care will be to gauge roughly the probable amount of green fodder with which he has to deal. In estimating this he may calculate that a crop which would make $1\frac{1}{2}$ ton of hay to the acre will make something like 5 or 6 tons of silage to the acre. To be on the safe side, for the present purpose, he will do well to take the higher figure. Supposing, therefore, that he has 10 acres, which he estimates at $1\frac{1}{2}$ ton of hay to the acre, he would reckon that he would make a stack of 60 tons of silage. He would then decide whether he should make one or more stacks of his crops. Generally speaking, the larger the stack the better, inasmuch as the proportion of exposed surface is less. He will then choose the place or places which will be most convenient both for present stacking and for future cutting out. In most cases a situation in or adjacent to the field itself will probably be desirable, as the carting will be a less serious matter when the time comes for feeding the silage than it is at the time of stacking.

At this stage of the proceedings—if not earlier—a decision will have to be arrived at on the important subject of pressure. And here probably the tyro in ensilage-making will be perplexed. There is such a wide variety and large number of "methods," each of which has its special advocates, that in the multitude there is bewilderment. Nevertheless, though the details of ensilage-making differ, there are at the bottom of it certain principles which may well be borne in mind, and which, if borne in mind, will help the farmer either in choosing a method or arranging one of his own. It is very difficult to go far into this subject without traversing something which somebody believes; but nearly all experienced makers of ensilage will agree upon the following general principles as the basis of successful ensilage-making whether in silos or stacks:—

- 1, That the character of the silage depends upon temperature.
- 2, That the temperature depends upon pressure.
- 3, That in early stages pressure should be controllable.
- 4, That the pressure should never be taken off until the silage is used.

It will be observed that each of these requirements is completely met by the use of dead weight, which after all is the ideal form of pressure. Unfortunately, however, there are very often considerable difficulties in the way of the employment of dead weight. Where a silo is sunk in the ground there is probably no kind of pressure so economical as that of stones, bricks, or earth, and there is none which is more satisfactory in every respect. But in a built silo or on a stack the labour of lifting dead weight up and down is very considerable, and some mechanical means of applying pressure is probably in most cases preferable. This may be either one of several patent methods, or it may be arranged by the ingenuity of the farmer himself. On the whole we should recommend for a first attempt, unless—as aforesaid—it be in a sunk silo, the purchase of one of the well-tried systems of pressure, such as those which are associated with the names of Blunt, Johnson, Reynolds, or Wilson.

INVENTOR OF HAY-DRYING MACHINE.—A correspondent reminds us that the address of Mr. Gibbs is Guilwell Park, Sewardstone Green, Chingford, Essex.

REMARKS.

9th.—Dull early, heavy showers from 10 to 11 A.M., and showery till midday, fine evening frequent lightning from 8 to 10 P.M.
10th.—Frequent showers throughout, but occasional sunshine in afternoon.
11th.—Bright and fresh.
12th.—Bright and warm.
13th.—Foggy till 9 A.M., then bright with easterly wind.
14th.—Spots of rain early, bright warm day.
15th.—Generally bright and warm, but rather close; slight showers at night.
A fine pleasant week, with high barometric pressure, and temperature about the average.—G. J. SYMONS.

GUMMING IN FRUIT TREES.

CONTINUING this subject from page 258 last week, it may be noted that trees worked on hardier stocks have gum almost exclusively in the scion, the part below the junction of stock and scion being free from disease. This applies equally to standard or dwarf trees—*i.e.*, long stems or short stems of the stock; indeed the stock in most instances remains healthy after the tree above the junction has all but succumbed to gum. What is this evidence of? That the stock is hardy and healthy. If so, it is conclusive of the care exercised to procure stocks that will produce trees of the most desirable form in the least time. It is healthy, and in every way suitable as a stock for the purpose desired by a rearer of fruit trees for sale. That may be, but what of the bud? Is equal care taken that it be of a healthy kind? There is no, and has been no gum on the tree from whence the bud is taken. If so, my objection ceases; but if the bud is taken from a tree that has been (if not then) affected with gum, it is, to say the least, tainted, and is predisposed and liable to exhibit the disease from inherent tendency sooner or later; indeed it only awaits certain climatic or cultural conditions to obtain in order to induce disease. The trees may not have gum so long as the effort is directed towards the production of wood, and the parts formed are annually cut away to an eye or two at the base on the hard pithless ripe wood. What if the trees are not transplanted so as to check the undue vigour that must result from the hard winter pruning? Gumming is certain, and not less so if the growths are retained instead of being lopped. It is when the vital forces are, or should be, directed to reproduction, that gumming appears. It may be on the current or the preceding year's wood, a present or a consequence of plethora, a deficiency of the power of elaboration and assimilation, resulting through the want of leafage to evaporate, or restraint of evaporation from deficiency of light and air, combined with excess of moisture, or directly caused by large reductions of foliage at a time as in disbudding, or allowing the growth to become crowded and then removing it by armfuls. But not to anticipate, let us keep to the young tree. It is in the nursery rows—a stout short-jointed tree, without a tendency to throw laterals from the shoots at some little distance from its origin, going its full length without lateral formation. It is not unduly strong—in no sense gross—its wood is firm, and its buds are prominent in the axils of the tree. It is a safe tree. Mark it. Reject the gross tree, and the weakly; the former is already plethoric, and the other is sure to become so when planted in soil such as is provided in culture. Of course there is a remedy; the gross tree may be lifted and cut hard back, and the weakly not given too rich soil, so as not to cause it to pass all at once from poverty to luxury. There is nothing, however, like the healthy tree to begin with, and if there is any trace of gum, or dead patches on the bark, the stock is unhealthy and only fit for burning.

How does the tendency of a tree to disease come? Budding on a stock fully a hundred times its strength, the aliment of a hundred parts being forced into it by the heading down process, it makes in a season as much growth as the stock required to effect on Nature's plan in three to six. It is the way to get a strong tree of a desired kind in little time. No question arises as to its being a ready means of transforming a wildling into a useful tree, but is it not conducive to disease? If the stock when worked be gross it will transmit that grossness to the bud or scion, and I shall submit that

grossness is the predisposing cause of gumming, induced in the maiden tree by the luxuriance of the stock. The stock may be hardy, which is sufficient to account for its immunity from gumming and the obstruction to the descending current by the junction tends to increased vigour of scion, so that it stores up more food than it otherwise would, and as a result earlier puberty ensues than would be the case were the stock allowed to follow Nature. The gross maiden tree is not so certain of forming fruitful parts as the moderately vigorous; the former has larger sap vessels, and as such is more liable to suffer from vicissitudes of climate, making a late growth, and the wood is not nearly so well ripened. It is liable to rupture of the sap vessels through their containing watery unassimilated sap in severe weather, showing evidence of injury before it is headed. It is plethoric as a maiden and never forms a healthy tree, for if lifted as a maiden the plethoric part—*i.e.*, the few inches of the first year's growth remain, and it is on that part that gumming appears in otherwise healthy trees, and to which they ultimately succumb. This is very common with Cherries—*viz.*, gumming is most prevalent on the part immediately above the junction of stock and scion; it is common enough in Peaches, Apricots, and Plums, whole branches dying off from gumming at the point of origination, the result of error in the early stages of its existence. The stock being a means of acclimatising certain fruits it does not necessarily follow that plethora is certain to result in climates unfavourable to them, though we find trees outdoors are more subject to gum than those grown under glass, indeed we have evidence that trees against walls very much injured by gum were less so when enclosed in a glass case, and still further free from the malady when artificial heat was employed, as immunity or otherwise from this disease depends on the plethoric development in the first instance, the after weakness being a consequence of the disease. Roses that succumb to some disease akin to gum on the Briar are perfectly healthy on their own roots, and I have a Coe's Golden Drop Plum all but a skeleton through gumming, whilst the stock on which it had been worked is perfectly healthy, the stock being Green Gage, and fruiting freely.

The facts, therefore, on which we rest are—first, healthy stocks as the basis of immunity from disease, whether it be in the origination of new or the perpetuation of improved kinds, for by whatever means this is effected we have little to hope for but the perpetuation of disease in the progeny of a diseased parentage. The seed is no alleviation, as gumming is quite as pronounced in the stone of a Peach or Plum as in the branches, therefore rejection must be made of both when diseased as agents of reproduction. Second, the avoidance of what, through inducing over-luxuriance, is calculated to and does predispose to disease. Third, keep from sudden checks to growth and their reaction.

In contending with the disease we have to make as sure as cultural judgment can of the cause or inducements. In the case of Peach and similar trees it may arise from looseness of soil, deficiency of calcareous matter, too rich humus-forming matter, defective drainage, whereby the soil is made sodden and sour, and too close and moist an atmosphere. Checks, such as injudicious ventilation when the external atmosphere is sharp and cold, extreme or full disbudding instead of little and often, large reduction of growths, and keeping the tender growths constantly wet in dull, cold periods. The remedy for looseness of soil is to firm it; for deficiency of calcareous matter is to supply chalk or marl, clay marl to light soil, siliceous marl to heavy; too rich or humus soil is to correct it with lime, or phosphates (mineral coprolites), or marl; inefficient drainage suggests rectification, and a close atmosphere will prompt freer ventilation. Checks by whatever caused have their remedy in a judicious pursuing of opposite treatment.

The best remedy against the disease is destruction of the affected parts, but which, strictly followed, would in many instances mean the destruction of the trees. What we insist upon is

that no tree be planted which at the time is affected with gum ; that it be uprooted if it show traces of gum on the stem or the main radiating branches near the stem ; and no tree be allowed to remain when the disease pervades the tree to a considerable extent. In cases of that description cure is hopeless ; therefore, our remarks on remedial measures are only intended to apply to trees affected which can have fresh parts originated from those that do not appear affected or derive sap through parts that are not diseased, as it is useless to seek other than mitigation if the disease has possession of the tree at its base.

Bearing in mind that the disease occurs most frequently and is greatly encouraged where the soil is too rich from over-manuring, too great width, depth, and freedom of rootage, and growth consequently over-luxuriant, we must seek a remedy in poorer soil, lifting, and root-pruning. It will not answer, however, to transfer a tree from a very rich soil to a very poor one at once, for the roots that are suited for the collection of food from a rich soil are not quickly adapted for the absorption of that from a very much less abundant pasturage. Restriction of the rooting area, especially of depth, and reducing the staple of the soil by removing some of it and admixing less fertile soil or chalk, is often of great service. It will in most instances suffice to add old mortar rubbish and road scrapings, and make the soil firm so as to induce stout, short-jointed, fruitful food. It gives time for thorough solidification, the supply of aliment being steady and not liable to influence by "fits and starts" to anything like the same extent by atmospheric conditions as that afforded by roots rioting in a loose, rich, deep soil out of all proportion in extent to the requirements of the tree's health, the power of evaporation and elaboration by the leaves, and assimilation in the buds and adjacent parts of the tree's structure. Lifting and replanting in rectified staple of soil is the only means by which gumming when induced by over-luxuriance can be rectified and prevented in cases where the cultivator has command more or less of the climate by means of glass and artificial heat ; and where the weather controls the cultivator's operations judicious lifting, root-pruning, and attention to soil influences will aid considerably in combat with the disease.

Removing the infested parts, cutting them clean away below the infection into sound wood, and at once burning them, is the surest way to prevent contagion, delay in this respect being a wholesale means of spreading the disease. Removing large branches at pruning time should be avoided ; indeed summer pruning should take the place of winter pruning, gross growths being restrained by stopping, or removed in order to an equal distribution of the sap, and insure an equality of medium and thoroughly solidified growth throughout the tree, and then we may look for health and fruitfulness.—G. ABBEY.

PLANTING DAFFODILS.

THERE is perhaps no better month in the whole year for planting the majority of Daffodils and Narcissus than September, though some growers make a start even earlier. Such, however, are exceptions, and not the rule ; indeed private individuals have not the opportunity of procuring their bulbs much before this date, and all bulbs this year are exceptionally late in ripening. In the course of lifting some Daffodils during the present season I have witnessed several instances in which the new roots have been emitted while the foliage was still green, the result, no doubt, of the great rainfall. On the whole, this season, the ripening process has been irregular, and particularly was this so with the Tenby Daffodil, biflorus, ornatus, and the double Poet's Narciss. Judgment and forethought have been necessary, and the more so in heavy loamy soils, all of which has tended to a later harvest in the bulb trade than has been known for many years. The great downpour of rain has not, however, interfered in the least with the quality of the bulbs, but has produced them decidedly superior to seasons where a scorching sun is upon them before they are scarcely out of flower : the process of ripening has been more gradual, with the result that the bulbs, when lifted and properly dried, have turned out excellent. With regard to lifting and storing them, I will only say that it is too late to attempt it if not already done, as many are already rooting freely that have not been

disturbed, therefore to lift them and lose all their new roots would be a serious error. But now a few words as to planting them and their general cultivation.

Regarded collectively, the majority of Daffodils, and particularly the grand Trumpet varieties, which belong to the magni-coronata group, delight in a deep rich fertile loam, such as fresh turf from a pasture. In this they delight, though it is not forthcoming in a great many instances, and they have therefore to be planted in something else. They are by no means a fastidious group, however, as may be gleaned from the manner in which some thrive in cottage gardens that have not been disturbed for years, where they have grown into large masses, too crowded, it may be, to flower with their wonted freedom when under good cultivation ; for let it be borne in mind that while these cottage garden clumps appear to thrive, the number of flowers will be very small as compared with the number of bulbs. Like all other plants, Daffodils cannot grow to perfection when left alone. If one of these large clumps be examined, it is most likely there may be fifty or a hundred bulbs of all sizes heaped one on another, and probably not a dozen flowering bulbs in the whole. The case is quite different with Daffodils under cultivation, when single bulbs (I allude more particularly to the old double Daffodil) will produce three, four, and even five flowers each ; thus illustrating, on the one hand, the plant in a semi-wild condition, and on the other, the result of high-class cultivation. I mention these extremes to show that Daffodils, even when planted in shrubberies or semi-wild places, are much benefited by periodical lifting and separating.

The majority of Daffodils are very accommodating as to position, and may be planted in the herbaceous border proper, or fringing a plantation of Rhododendrons ; on grassy slopes ; in shady groves ; in the woodland or wild garden, or in fact any place out of doors where a fair depth of good soil may be given them. Not the least important feature in connection with many of them is their adaptability for forcing and for pot culture under glass. Only a few years ago the rich and varying tones of gold and yellow, which are now so much admired in these Daffodils in the early spring time, were considered vulgar, and as a gardener recently observed, in speaking of Daffodils as cut flowers, "We hardly dared to send them in the house with other cut flowers, and now they are all the rage." And so it is. Fashion and tastes quickly change, for who would have thought a few years ago that our common double Daffodil would ever become sufficiently popular and valuable that bouquets chiefly composed of them should figure prominently in leading West End florists' windows ? Yet it is so, and extremely effective they are when arranged skilfully, and at the same time they are very enduring provided they have not been forced too hard. As pot plants in the conservatory or the drawing-room they are highly ornamental, and are being more eagerly sought after year by year.

But no matter for whatever purpose they are required, whether it be for pots or for the open, no time should now be lost in obtaining supplies and having them planted at once. For pot culture the best plan to adopt is that which most growers employ for Hyacinths, Tulips, and the like, covering with a few inches of cocoa-nut fibre refuse or coal ashes. In this they will be safe for eight weeks or thereabouts, by which time abundance of roots will be formed, when they may with safety be introduced into gentle heat. The only difference I would make with Daffodils for pot culture would be to bury them completely in planting, and not, as is the case with Hyacinths, leave the apex of the bulb above the surface. Daffodils when first introduced into heat need not occupy the stages ; they may be placed beneath them, provided they are not in contact with or even near the pipes, as that would mean a serious injury to their flowering. If left plunged in the ashes a longer time than I have stated some of the earlier ones may have commenced growth, in which case they should be shaded from full light for a few days. In planting them in the open ground they are not so easily accommodated, unless it be in instances where beds are devoted to them, when the planting is simple enough.

In all gardens where light sandy loam abounds Daffodils are easily accommodated, and may be planted from 4 to 6 inches deep for the larger bulbs, such as Empress and Emperor, Golden Spur, and spurius, while 2 or 3 inches deep will be ample for such as the Hoop Petticoat section and those generally of small stature. For the more delicate, such as cernuus, cernuus plenus, albicans, odoratus plenus, pallidus præcox, nobilis, scoticus, and moschatus, a maximum depth of 3 inches will be sufficient ; in heavy, holding, and clayey soils further precautions will be necessary in the shape of abundance of sharp grit, burnt earth, and leaf soil to render the soil as open and light as possible. The stronger varieties do not object to heavy soils provided they are well drained, in which case they are benefited by abundance of sharp sandy grit, which is not so important on lighter soils.

Another important point is that of manure for Daffodils. This

us, however, a question which individuals must settle for themselves, depending as it does in its entirety on the condition of the soil. A rich fertile loam will grow Daffodils perfectly without manure of any kind, while a poor, hungry, or gravelly soil will be benefited by a good dressing of cow manure worked in 3 or 4 inches below the bulbs, or failing this a good soaking of liquid manure may be given with excellent results when the roots are most active—viz., from September to end of January. The idea of supplying liquid manure in winter to these and other bulbous plants has not received the attention its importance deserves, and is probably overlooked at a season when rain or snow have made the ground sufficiently moist for most things; but not only is it highly beneficial to Daffodils and Narcissus, but to Lilliums, Spanish and English Irises, tuberous Anemones, and, in fact, the majority of bulbous plants which make a quantity of fresh roots annually.

For anyone desiring a select series of Daffodils and Narcissus to form a start, I have given the names of some of the best and most useful: *Corbularia conspicuus*, the golden Hoop Petticoat; *princeps*, sulphur and yellow, good for forcing; *nobilis*, sulphur and yellow, trumpet reflexed and fringed; *maximus*, deep golden, a fine flower; *obvallaris* (Tenby Daffodils), the best forcing variety of single Daffodils; *Telamonius plenus*, the old double Daffodil, grand for forcing; *spurius*, *spurius major*, and *coronatus*, all excellent for a second early batch indoors; *Golden Spur*, a grand flower for any purpose; *Emperor*, the grandest of all its tribe, too valuable for forcing; *Horsefieldi*, an exquisite flower, will force steadily; *Empress*, a noble flower of great merit; *rugilobus*, a useful variety very free flowered; *cernuus* and its double form, *moschatus*, *albicans*, *Wm. Goldring*, *cernuus pulcher*, *tortuosus*, are all charming in the garden but not suited to growing in heated structures. Next I would name a choice kind which is always admired—viz., *pallidus præcox*, a pleasing sulphur shade and most useful; then in the incomparable group are *Stella*, *Glow*, *Cynosure*, *Princess Mary*, and *Sir Watkin*, each distinct and good. *Barri conspicuus* is remarkable for its large spreading perianth segments of sulphur and yellow, and cup stained with orange scarlet, this is exceedingly showy. To those named may be added *poeticus ornatus*, *poeticus plenus*, and the sulphur and orange *Phoenix*; *poeticus ornatus* is the best white forcing variety in cultivation, and its flowers by the tens of thousands find their way into Covent Garden Market from January to April inclusive.—J. H. E.

WINTER CUCUMBERS.

DURING the summer months Cucumbers can be grown in almost any structure with success, but this is not the case when a supply has to be maintained during the winter. The best of conveniences are essential to success. They cannot be satisfactorily grown with other plants beneath them as may be done during the more favourable months of the year. The structure for this purpose must be of the lightest description, with plenty of bottom and top heat at command. A temperature of from 60° to 70° at night must be maintained; with a rise of 5° by day at the least. This should be obtained without having to over-heat the pipes. Nothing is more detrimental to the well-being of these plants than making the pipes burning hot, as the foliage is certain to be attacked by red spider. If the temperature cannot be readily maintained without over-heating the pipes it is almost useless to attempt the culture of Cucumbers. Applications of insecticides and other strong measures would soon destroy them; in fact, if the syringe be used sufficiently frequently to keep the red spider in check would do more harm than good; the plants at the most trying period of the season would be certain to fail. Under any circumstances the temperature must be regulated by external conditions. When the weather proves severe the lowest named only should be maintained; in fact, if the thermometer reads 60° early in the morning and then rises it will be more suitable to the plants than a higher degree. On mild occasions, when it is 45° to 50° outside, the highest figures may be kept up with beneficial results to the plants. The supply of bottom heat is equally as important as the top, and should range from 75° to 80°, the same conditions being observed as advised for the top.

The manner in which the bottom heat is applied is also important. It is a great mistake to have the pipes any great depth below the base of the soil, and it is equally bad, if not worse, to have them arranged so that they unduly dry the soil. In the arrangement of a house for this purpose preference would be given to a plan whereby the pipes could be utilised for both top and bottom heat. They would not be confined, but slates half an inch thick, or nearly, would be laid practically on the top of them; in fact they would be arranged so that the flanges of the pipes were just clear. A clear space would be left near the outer walls of the house, 2 or 3 inches in width, or even the space of a 4-inch pipe. This insures the whole of the soil in which the plants are growing being of a

uniform temperature. However much piping may be employed for bottom heat, if the soil is against the outer walls it is damp the whole season, and many degrees colder than that nearer the inner walls of the house. Such arrangements materially lower the temperature of the soil throughout, and have a very detrimental effect upon the plants. If the bottom heat pipes are enclosed within the bed the chamber for the pipes should be covered with earth, not filled in with rubble as too often is done. There should also be room between the outer wall and the wall of the bed for one or more top heat pipes. Slates absorb heat quickly, and it is imparted to the soil without having that drying effect which is the case when the pipes are merely covered with loose rubble. When a crating of dry material is formed over the rubble the heat fails to pass through to the soil above. If slates are used it is not wise to lay the soil directly upon them, for they hold water by this means to an extent that cannot fail to be serious. This evil is overcome by placing on the slates about 2 inches of drainage, which allows superfluous water to pass away readily.

There can be no doubt that a lean-to structure facing south, with a shed or other building behind it, is the best for winter Cucumbers, being much warmer than a span-roofed house in any position, although they can be grown in the latter if it runs north and south. If it runs east and west those on the south side may do well, while those on the north will not succeed. It is a general custom to arrange the wires upon which to train the plants 14 or 16 inches from the glass, thinking that the nearer to the glass they are the better. This is the case with those grown during the spring and summer, provided the foliage has room to develop itself. But for winter culture the case is different. The wires should be 20 inches from the glass, and it would be better for the plants if they were 2 feet away. The footstalks of the leaves are very liable to grow longer during the winter than when they can enjoy plenty of light and air during the summer. When planted at only the ordinary distance from the glass they are apt to crowd themselves against it and hold too much moisture. Another advantage, and the principal one, is that they are much warmer than when they are close to the glass, and not so liable to injury from cold.

Those who intend growing Cucumbers through the winter should plant the whole, or part of their early house, in June or the beginning of the next month, so that they can insure a supply of fruit until the end of November. Many winter Cucumbers fail towards the close of the year, or before, by cropping them too early in the season. Early cropping, whether the plants are intended for spring, summer, autumn, or winter, is one of the gravest mistakes. It is a general custom, and it is a very bad one, for it practically destroys the vigour of the plant for a long time. With winter Cucumbers this practice must be strictly avoided. The plants should cover a good portion of the trellis before they are allowed to fruit. If this is done, and the fruits that appear are removed until the middle of November, they will, with moderate cropping, afterwards yield a supply during the winter.

To give the plants every chance of doing well, sturdy plants in 5-inch pots must be placed out at once. If plants are not raised seed may be sown at once, but no attempt should be made to fruit them before the middle of December, but temporary plants may be placed amongst them to yield a few fruits until the others gain strength. For winter work the plants should not be placed nearer than 3 feet, and allowed to extend up the trellis about 4 feet before they are pinched. Every attention must be paid to them from the time they are planted, so that the growth they make is short-jointed and of the sturdiest description. This can be accomplished by ventilating liberally whenever the weather is fine. A moist close atmosphere that will encourage soft quick growth must be avoided from the first. If this is done they will attain considerable strength by the time the leader is pinched. The laterals should be removed to the lowest wire, and then allowed to extend until they meet, when the points of the shoots should be removed, the laterals being at least 16 inches apart, so that ample room will be left for training the sub-laterals on which the fruit is to be taken. It will be necessary, as these are laid in, to remove some of the main leaves to give the foliage of the sub-laterals room to develop. As a rule, they will show fruit at the first joint, and should be pinched one joint beyond, all the fruits being removed but one. Some of the sub-laterals will need removing to prevent crowding, and this is best done as soon as they start from the laterals. All growths afterwards may be pinched at the fruit, and not one joint beyond. By this means the wood can be removed from time to time as the fruit is cut, and thus afford ample room for fresh fruiting shoots. After the plants commence fruiting they must not be overcropped. If too many fruits show, remove them directly it can be ascertained that the required number will swell. It must be remembered that each fruit takes more than double the length of time to swell than is the case during genial weather. It is often necessary

during bad weather to fertilise the flowers, and if this takes place the strain upon the plants is very much increased.

The soil for winter Cucumbers is important. In the summer they are not particular, but in the winter the soil must be of such a nature as to avoid a quick soft growth. It should be composed chiefly, if not entirely, of good fibry loam. This depends upon its fertility. If it is rich it may be used alone; if not, one-seventh of manure may be added. Some loams are poor, and such that we are in the habit of getting here must be enriched with manure for Cucumbers, both during the summer or winter. The soil must be well warmed before planting; and here it may be mentioned that the structure used must be thoroughly cleaned. This is not only necessary at the commencement, but those residing in the neighbourhood of towns will find it requisite to wash the glass outside frequently. Winter Cucumbers do not need so much soil as might be given with safety during the spring or summer. Two bushels for each plant will be ample, with attention to top-dressing them from time to time as they need it. Frequent top-dressing is infinitely better for winter Cucumbers than having to resort to feeding. After the plants commence fruiting a little Clay's Fertiliser sprinkled on the surface of the soil will be found better than stimulants in a liquid state.

The amount of water needed during the winter is considerably less than during the more genial months of the year. They must be kept as near as possible in an intermediate condition. Great care must be exercised in this matter; too much water is as detrimental as too little. Do not supply water at a lower temperature than that at which the bottom heat is maintained. The syringe may be used freely at first on all fine occasions, but it must be gradually discontinued, and may be needed only on bright days during the months of November and December. It is not difficult to keep plenty of moisture in the atmosphere during these months without reverting to the syringe, which one is often tempted to use after bright sunshine, but if it is not done early in the day, or is followed by sunless weather, the operation does more harm than good. The atmosphere can be kept moist by damping available spaces, but too much moisture in the atmosphere during the winter will soon prove as ruinous to the plants as cold. In an atmosphere overcharged with moisture the plants soon fail, they give very little warning; first they flag under bright sunshine, and if they are examined the tissues will be found to be in a state of decay.

The house should be liberally ventilated at first to insure a sturdy growth, and as the season advances air must be admitted with great care and caution. No ventilation would be needed after the end of October if it was not for the condensed moisture that becomes deposited at night on the glass and wood of the house. A "chink" of ventilation early in the day quickly dispels the moisture that hangs about the woodwork, which is much better for the plants than being subjected to a constant drip throughout the greater part of the day. If the rafters are grooved, or even have a strip of zinc on them, this condensed moisture can be carried away without subjecting the plants to a shower bath daily. It is a good plan to supply the house with canvas blinds, which keep the house many degrees warmer, and prevent to a very large extent the condensation of moisture that would otherwise take place.

Telegraph, Cardiff Castle, and All The Year Round are good for winter growing. A cross between the first and Paragon results in a good useful variety for the winter. It is questionable if any surpass Telegraph for this purpose.—WM. BARDNEY.

GLADIOLI NOTES.

OWING to shows and exhibiting thereat I had no time to note results during the past two or three weeks. In the first and second weeks of the month seven dozen spikes were cut and exhibited, beside quantities for home use. No particular note was made as to number of varieties, but the following were all in flower in larger or smaller numbers, besides sorts already noted, many of which still continue to open blooms, as for instance, Shakespeare, Opale, Horace Vernet, Carnation, and many others. One of the finest which has bloomed is Enchanteresse, of which I had two spikes open at once. This is the best light variety we have yet flowered, its only fault being a too close habit, so causing the very large flowers to become somewhat jammed on the spike. It is a variety requiring time to develope. Grand Rouge has given four fine spikes; this is a good variety. Eugène Souchet, the first only opened a most beautiful deep rose and white; a perfectly formed spike. Fra Diavolo is a very fine orange flower with pure yellow blotch, and of a lighter shade; in the same way is Pyramide a very good sort. Flamboyant we have fine, a very bright variety, and making a telling spike. Africain is a dark slaty crimson, not so good as Tamerlane, which has longer spike and larger and brighter

flowers. Ondine, a white and violet-flamed variety, is very fine this season. Orphée has also been good. A variety in the same was as Orphée, but later and just unfolding its blossoms here, is Teresita, a strong growing very good sort. Hesperide and Lady Bridport belong to same class, light ground with salmon flake, both free and pretty.

Leviathan has been very good, spikes long and flowers large. Daubenton is a lively lilac flower, a good variety, and making a good spike. Rayon d'Or, straw flaked with carmine, has yielded some good spikes, though rather short. Pactole is a better variety with longer spike but flowers not so large. Brennus, a bright lake with large white blotches, has been rather small; a very bright sort. Amaranth, a flamed variety, has very large flowers, but rather dull. Ciceron, rather deeper in the shade but not so good a variety as above. Crêpuscule, a very soft flamed lilac variety, is very good indeed. Macaulay is a very good large sort but rather loose. Other varieties are Zenobia, Madame Basseville, Madame Dombrain, Penelope, Grand Lilas, Parmentier, Sylvie, Baroness Burdett, Coutts (a good deep lilac variety), Victor Jacquemont, Orange spotted, Octavie, Argus, Elvira, &c.

There are still a good few varieties to open, such as Amitié, Cameleon, Phoenix, Le Vesuve, &c., but even these late varieties may be flowered by this date, and earlier by allowing them a longer period under glass before planting out.

We have experienced since about the 12th of the present month a very beneficial change of weather, and the young corms I find are swelling up very fast. The earlier sorts will be ready to lift in the course of the next ten days, as nothing is gained by leaving the corms in the ground after the foliage has yellowed. Indeed a change to wet sometimes induces renewed root action in these early kinds, which cannot be otherwise than mischievous in its tendency. Careful growers do well to inspect the corms of such kinds as Ad. Courbet, Mons. Ad. Brongniart, Shakespeare, Horace Vernet, Albion, Opale, and others which have flowered a few weeks back, and lift them as soon as root action has ceased. Later kinds may be greatly helped by inserting a spade or fork underneath the plants, and giving them a slight upward heave. This will help the ripening process considerably. Any varieties of value which may appear to be too late to open this autumn should have the spikes removed in order to induce the plant to swell up the young corm instead of wasting its energies on the spike, which may in the end be too late to develope for cold.—B.

NOTES FROM A HERTS GARDEN.

VEGETABLE crops in 1888 have been and are plentiful and good. There have been as usual various degrees of excellence and imperfection in the different crops, therefore I shall be equally as careful in condemning the unsuccessful or in praising the satisfactory.

PEAS.

Early Crops.—Early in December, 1887, a first sowing was made of Veitch's Extra Early and Dickson's First and Best on a south border. The seed was wetted with petroleum just before sowing, the seed covered with soil lightly, and then an inch thickness of sifted ashes given as a further safeguard against mice and slugs. The soil is light and rich from repeated additions of opening material, working, and manuring. A sunny, sheltered spot had been used for early Peas, nobody knew how many years consecutively. The germination was not good. Something was wrong with the seed. Something preyed on the sprouts. The root stems were rusty, cankered. In result there was about half a crop; in 1887 the crop was little better. Is the soil Pea-sick? The border was sown with Prickly Spinach early in August, 1887, in rows 18 inches apart, every third row being left out for the Peas. The Spinach was all that could be desired, and now, after the Peas of this year, there is Snow's Winter Broccoli as sturdy and as blue-green as the most fastidious could desire.

A sowing made in pots under glass in February of Veitch's Extra Early, hardened off and planted out in April on a south-west border, staked at once, protected with evergreen boughs on each side the rows from cutting winds and frost, afforded a first gathering on June 15th, a full fortnight before those sown outdoors. At the same time as those sown in pots William I., William II., and Day's Sunrise were sown on a south border. These were superb. The soil is similar to that where the first sowing yielded only half a crop, but it had not known Peas for years. There is therefore something after all worth considering in rotation. Of the three sorts William II. was much the best, and only a few days behind William I. It is well worth waiting for. Day's Sunrise is, from filling its pods indifferently, a "sunset" amongst early Peas.

Second Early.—The soil where the second-early crop was sown I

had turned over two spits deep and the bottom forked over, but the top soil was kept at the top, in fact left much as it was before, only moved and mixed, the manure being mixed with the top spit. I sowed *Gladiator*, *Triumph*, and *Criterion*, the two first growing about 3 feet high, and *Criterion* 6 feet. *Gladiator* was simply "a sight" of pods from near the bottom to the top of the haulm, and the crop prodigious. *Triumph* is a large-podded and blue-wrinkled Marrow of the first order as to quality and crop. *Criterion* is, as I have found it everywhere, the best second-early Pea, crop and quality being the tests of merit.

Main Crop.—We relied upon *Criterion* with *Telephone* and *Telegraph*. The two latter though good, were not up to their usual standard of excellence. Are they less carefully selected? *Duke of Albany* proved excellent, and the quality all that could be desired, yet it was not nearly so prolific nor had such well filled pods as *Prodigy*, which was a picture from the abundance of large handsome pods, and the quality is superb.

Latest Crops.—*Autocrat* grew very robustly, and formed a broad row from its branching habit, and it bears very low down for a tallish Pea. It grew over 5 feet high, and has large rounded pods well filled with large deep green Peas, the crop not coming in all at once but successively. My impression of it is, that as a main crop and a late sort it is unrivalled, and the intention was to save all for seed, but so highly was it esteemed at table that not a single pod remained, and the only consolation granted on remonstrating about the Peas being all gathered was in the reply "they would have 'em." Best of All were the most indifferent of the kinds grown, *Sturdy* being very much better, indeed it seems to have a very much harder constitution, and is a "come again" sort, the crop being produced successively. *Ne plus Ultra* fully maintained its reputation as "one of the best" tall-growing late sorts, in fact a carefully selected true stock of this Pea is *Ne plus Ultra* as a "green" sort; and as a "white," which come up to the crop and delicious flavour of a true stock of *British Queen*? All points considered the latter was the best Pea of the year. It is not so showy either growing or dished as the best sorts, comparing badly with "King" and "Emperor," but the "proof of the pudding is in the eating," judged by which standard *British Queen* is the best.

Now we come to the selection, as follows:—Earliest, *Veitch's Extra Early* and *William II.*; second early, *Criterion* and *Prodigy*; later crops, *Autocrat* and *Ne plus Ultra*, with *British Queen*; for exhibition, *Duke of Albany*. If the height is a consideration, then in second early, *Dr. Maelcan* and *Triumph*; and later crops, *Best of All* and *Sturdy*, with *Marvel*, the earliest being the same as before.

There may be better sorts, of which I shall be pleased to hear in order to test them, which are influenced by the practice. I tried to grow Peas this year on ground merely dug a spit deep, on others turned two spits deep and the bottom loosened, mixing only, and not bringing the bottom to the top, and trenching two spits deep, cleaning out the bottom and pointing it over, but bringing it to the surface, yet the bottom spit was placed at the top. The ground was well manured, and in all cases the manure was put down a spit deep. It may be as well to observe that our manure is that of stables, cow houses, and piggeries, simply mixed by turning and made—i.e., the strawy parts into manure by saturating with the drainings; indeed, it is used raw, spread evenly on the surface, and dug or otherwise put under when time and weather permit, which on a clay soil is not always. Then as soon after the Peas are sown as opportunity offer, or by when they have "slatted," we mulch the whole of the ground with the manure above indicated for the medium growers, and the tall ones as well if there is not a between crop, when the mulching extends 18 to 24 inches wide on both sides, but we like to mulch the whole, and do so when practicable. "What a waste!" Manure under a summer sun will evaporate. Really I cannot see any waste of manurial matter at all corresponding to its being placed in a mountain-like heap, steaming away its qualities in order to form a close soapy mass full of poisonous acids. "Muck middens," with the ammonia evaporated or given off through heating, and its soluble constituents run off by rains, may be convenient, but it surely is not the way to get the manurial properties distributed over a large area and utilised to the best advantage. Placed on the surface as a mulching it does not heat, decomposition takes place slowly, and it cannot evaporate when dry, and if wet whatever is soluble is carried into the soil. Anyway the mulching answers, and what is of more consequence it as a dressing is more valuable than an equal thickness of hotbed manure; in fact, we benefit the current crop to the extent of what otherwise would pass into the air or be washed away and leave the ground in better heart for a succeeding crop.

The Peas on ground merely dug were not so good in crop as those on

the soil stirred, but not turned upside down by fully a third, and those on the stirred soil were not so full in crop by a third as those grown on the trenched ground. The digging was effected in one-third the time of the stirred and trenched ground, which two last were about equal in labour, consequently we have a fair idea of the relative values of digging, deep cultivation without and with reversal of surface. There is, however, greater difference than appears, for by increasing the crop we increase the relative values of quality, which is the chief factor in estimating results. All the crops on the trenched ground were of a very much higher standard of excellence, except in the case of the early sorts, where earliness tells considerably as to value, but in other respects the results were identical.—UTILITARIAN.

GLOUCESTERSHIRE VIOLET (OR MINSTERWORTH) PLUM.

THIS Plum is named *The Prince*, but it is known in the Manchester market as *Gloucestershire Violet*. It grows freely in the alluvial soil of the Severn bank, and has existed here from time immemorial; indeed, it may be said to be almost indigenous, as it does not require grafting or budding for its propagation, but springs from the stone or from shoots growing from the roots, like the common *Damson*. It is an early Plum, ripening about a week after *Rivers' Early*. It is chiefly used for cooking or for jam, though as the flesh is soft it may be eaten without the consequences attendant on hard-fleshed Plums. In Manchester market, where it is chiefly sent, it obtains a much better price than *Rivers' Early*. The crop of fruit is uncertain, as the blossom is liable to be injured by spring frosts; but if the season is favourable the tree bears abundantly. The tree grows specially in the gardens of the cottagers, in the hedgerows, and on the banks of the Severn.—GEORGE VINER ELLIS, *Severn Bank, Minsterworth*.

FIG. 31.—GLOUCESTER VIOLET PLUM.

[The Plum in question is represented in the figure. The fruit is oval, sometimes obovate, with a contraction near the stalk, and suture well defined; skin dark mahogany, covered with a thin bloom; stalk from half an inch to three-quarters long; flesh greenish, quite tender, sweet, and pleasantly flavoured; stone small, long, and channelled on the back. The fruit separates very easily from the stalk, and the flesh separates freely from the stone.]

NOTES ON EARLY ENGLISH HORTICULTURE.

(Continued from page 144.)

THINKING men generally are now agreed that the Crusades, terrible no doubt in their evils while they lasted, were afterwards fruitful for good. They broke down the barriers between nations, promoted travelling, helped to diffuse knowledge, and certainly aided the progress of horticulture, also of botany, its kindred science. In England it is very perceptible that frequent foreign wars, and the long domestic troubles connected with the "Wars of the Roses," prevented both nobles and commoners from taking practical interest in any branch of gardening. Our forefathers were no students of hygiene, but they were quite wide awake to the fact that man's diet should be a mixture of animal and vegetable food. But they put into their broths and stews the leaves or stems of wayside plants still abundant everywhere, though we do not think of eating them. Then as regards fruit, beside the common berries of the woods, people had wild Apples, Pears, and Cherries. Near Fulham, for instance, a place well known in this century by its orchards, there were in early times many Apple trees growing amongst the Willows on land just above the marshes; Crabs, small and sour no doubt, but they served for food, raw or cooked. Herbs, to be used as flavours or medicinally, were cultivated in gardens attached to the residences of the nobles or citizens, but ornamental gardening was as neglected during the Middle Ages of England as in the Saxon and Danish period; the lack of refinement forbade any interest in the culture of flowers. It is a curious fact that of all Europeans the Dutch are believed to have been the pioneers in the art of gardening after the decline of the Roman Empire; there is evidence that before the Crusades they had given attention to this subject, and sought out plants from other countries. Later in their history the ornamental details of their lace and linen manufactures would lead to the study of flowers; and it is

manifest that Holland has for some centuries had a great influence upon English horticulture, and will probably still affect it. The advertisements of the autumn season remind us of our indebtedness to this country for many varieties of favourite bulbs.

That to a limited extent, near London at least, fruit and vegetables were grown for the markets before the Tudors reigned appears from a side light we get from a quaint old ballad, which is undated, but belongs to the commencement of the fifteenth century. Its author was a Benedictine monk, and a friend or admirer of Chaucer. He tells how in the City streets people urged him to buy "Hot peascods," Strawberries also, and "Cherries on the ryse," this meaning, perhaps, Cherries on the natural branches, or else tied to sticks. About the Peas, we must recollect that our ancestors then were not accustomed to shell them, but boiled them in the pods, eating these whole as we do French Beans. Lydgate makes no mention of the vendors of Apples; such there may have been, but the costard-monger is not named till the time of Ben Jonson. For a good while now this word has had a wider meaning than it had then; originally it applied to one who sold Apples, specially Costards, picked probably in his own orchard on the north of the City. There is also in the City records of the reign of Henry VI. a petition presented to the Mayor by some gardeners of nobles and citizens, who had for an uncertain period been accustomed to sell pulse, Cherries, and other garden produce belonging to their masters in front of the Church of St. Austin, Broad Street. They had been driven away by the ecclesiastics on the pretence that their conduct was noisy and disorderly; after hearing both sides the Mayor thought he must appoint the gardeners another market, and he removed their stand to a place near the river at Blackfriars. About the same date, or earlier, we read of herb-wives, who brought for sale Basil, Saffron, Rosemary, and similar aromatics much in repute. In the fourteenth and fifteenth centuries, therefore, it seems many of the dwellers in London had gardens. The City guilds or companies had, most of them, halls surrounded by trees or shrubs. Apples, and perhaps Cherries, grew in the heart of the metropolis, for St. Martin Pomary, a church in Ironmonger Lane, Cheapside, was so called from the Apple trees that grew around it in mediæval times. Also some of the citizens who had a taste that way took plots a little distance from the boundaries, in what are now the unpromising localities of Spitalfields, Goodmans Fields, Whitechapel, and Shoreditch, where they grew more than they required for their own households, and sent the remainder into the public market, as we have seen. An ancient deed again indicates that a number of citizens, some 400 years ago, had ground near the City Road, their plots joining each other, and their occupations are stated. I find amongst them a large proportion of tailors or clothiers, which is a curious fact; I do not think a love of gardening is common in men of that calling now-a-days, though I have noticed it in many shoemakers. Part of this land cultivated by the citizens of walled London remained unbuilt upon until a date comparatively recent.

We have referred to the fact that the Romans paid particular attention to the Vine, training it on trelliswork, up poles, possibly also allowing to run along the side of warm banks; and we may assume the cultivation of this plant has been continuous in Britain since their occupation. Domesday Book informs us that in the village of Westminster one Barnard held from the Abbot four arpents of vineyard, and at Kensington Aubrey de Vere did service for three arpents. (It is doubtful what extent of land this word represents.) Other early allusions to vineyards occur. There was one in the village of St. Giles; another on the bank of the Old Bourne, in view of London city; yet we do not read of the street sale of Grapes. It is obvious neither Saxons nor Normans ate these to any extent; the Grape yield was utilised by being converted into wine.

Pulse, mentioned above as an article sold by the City gardeners, would include Peas and Beans; but it was not until the Normans arrived that Peas were eaten green. The Saxons allowed the pods to ripen and stored them. Mr. Glasspool points out that they were grown both in Scotland and England to some extent as early as 1299; for in that year an English force engaged upon a siege of a castle in Lothian had, from failure of their stock of provisions, to subsist for awhile upon the Peas and Beans they picked in the fields. Fosbrooke has also noted the fact that long before the Reformation the culture of the Pea was a specialty in some of the monastery gardens, and the monks used to compete with each other to produce Green Peas by an early date in Lent: how they forced the plants we do not know. Gerard, writing about the garden Bean, gave it as his opinion that it differed only through cultivation from a wild kind he found in many places; perhaps, while seemingly wild, a descendant from the Bean which the Romans grew in Britain, for it was a vegetable they much favoured. Other varieties of the Pea and Bean were certainly brought to our island by returning Crusaders. Spinach is thought to have been an introduction due to some monk or pilgrim coming to us from

Spain. For a long time its cultivation was very limited, but our forefathers are said to have used as a sort of Spinach, and even planted in their gardens, the wild species of *Chenopodium* called Bonus Henricus, also the Goosefoot, and named either after Henry IV. of France or Henry VI. of England. The leaves were boiled, and the stalks also scraped, peeled and eaten as Asparagus. It is not till the year 1502 that we get the first English work on horticulture by Richard Arnold, haberdasher, of St. Magnus, London. In this he discourses on grafting and planting trees, intermingling remarks on the four seasons and astrology. —J. R. S. C.

NOTES ON JUDGING.

It is pretty well known among rosarians that to be a good judge a man must be either an exhibitor himself or else a zealous attendant at Rose shows, with frequent opportunity of seeing good Roses in a growing state. It is astonishing how soon a man loses the "eye for a Rose" which will enable him to distinguish the different varieties apart as they appear in a stand. I have heard one who lives among the best of Roses all the year round say he cannot depend upon distinguishing all the sorts accurately at the beginning of a fresh season till his own Roses are out and his mind's eye refreshed as it were by all their different peculiarities. Secretaries of Rose shows should remember this, and if a difficulty arises in finding judges well up to the task see if it be not possible to arrange that different sets of exhibitors should judge each other, as this course generally produces complete satisfaction.

In judging Roses the following points have to be taken into consideration:—Form or shape, colour, stability, freshness, size, and beauty of arrangement. Those of our lady friends who are ignorant of the laws which govern the warriors of the Rose are always surprised in the first place at the rigidity of the golden rule that puts form before colour, and next, that scent, which they rightly consider one of the glories of the Rose, should be so ignored. In answer to the first point the rosarian will remind his fair companion that a perfect knowledge of colour will not enable an artist to make even a presentable picture if his drawing be faulty. And if he wishes to air his classical lore he will tell her that the ancient Romans (and she will probably concede that they knew something of art) had "form" or "shape" (*forma*) as their word for "beauty," and "shapely" (*formosus*) as their word for "beautiful."

With regard to scent, he can only plead that in a tent containing some thousands of blooms a man (with possibly in the past season a badish cold in the head) would find it a difficult task to judge Roses by their scent. But although it is well agreed that beauty of form should be the first consideration, there is not, I fear, the same unanimity as to the weight that should be given to the other points mentioned. On some few occasions I have thought that even too much consideration has been given to form to the neglect of all other points whatever; but as a rule most judges would probably place them in much the same order as I have named them above.

It goes without saying that at times there is such a discrepancy between the exhibits that a careful general survey of each will be sufficient. But, as a rule, every bloom should be separately noted, even in triplets. What I should call the rough-and-ready way is then sometimes used. The judge runs rapidly over each stand, counting the number of "good" Roses in each, and gives his decision accordingly. This seems to me a most unsatisfactory mode of procedure. In the same stand one bloom may be almost good and another very good, yet the first counts nothing, and the other only one. In a close contest this might surely result in a miscarriage of justice. In all shows of horses, dogs, and poultry, judging by points has been the only safe rule, and it should be the same with Roses. One bloom should be selected as the standard of so many points, and every other Rose in each stand should be awarded 0, 1, 2, 3, or even in the case of a medal bloom, 4 points. One of the judges should act as teller, and the others, one of whom should put down the figures, should watch and correct him if they differ from his estimate. It is best not to add up the totals till all the class has been once judged. Then, and not till then, in my judgment (others perhaps will differ) should beauty of arrangement, if necessary, come into consideration.

Form, then, being the first consideration, the question at once arises, What is beauty of form? Five different shapes or types of form are given and illustrated in the N.R.S. Catalogue—the cupped, the imbricated, the globular, the globular high centre, and the flat. Now, it seems to me that by rights two beautifully shaped Roses of any two of these five types should, *ceteris paribus*, have an equal number of points. As a matter of fact, however, the flat type finds no favour, and probably few would wish to give it an equal position with the others. But I am inclined to think that the other four at least should stand upon the

same footing. Yet this is hardly the case; the imbricated and the globular with high centre are the most admired forms, while the true cupped shape has fallen into disrepute. I say the true cupped shape, because Baroness Rothschild, which is figured in the N.R.S. Catalogue as the type, is hardly what used to be called a cupped Rose. I should perhaps have taken Coupe d'Hébé as more nearly representing the cupped type, and I remember once seeing a bloom of Anna de Diesbach, which was a most perfect cup, well filled up at the bottom, yet most regular and smooth in outside, inside, and edge; a prettier object by far, I thought, for the eye to rest on than the silver cup which it helped to win. Such a bloom is a hundred times more difficult to get than a perfectly imbricated A. K. Williams, or a perfect globular high centre Innocente Pirola.

Regularity and smoothness of outline are of course necessary to perfect beauty of form, but how are judges to deal with the five different types? Are they, or are they not, to consider each perfect in its way? A case occurred this season in which I had the misfortune to differ from brother judges. A celebrated amateur, a much better judge than myself, was the teller. He passed over a bloom of Heinrich Schultheis with 0 to its credit. I demurred. It was a good bloom in my estimation, regular and smooth in outline, the two outer rows of petals fairly expanded, the remainder standing well and regularly up; but, and here was the difficulty, the upstanding part of the bloom formed a cup—a good cup—well filled up at the bottom, and showing no pretence of an eye, but still it was hollow in the centre where it ought to have been high my confrères said, and I could not get one point for it. I called it a globular Rose with cupped centre, and opposed the dictum that a bloom should have no points because it was hollow in the centre, or what became of the cupped form? However, I was in the minority, poor Schultheis got no points, and the stand, by a very little, lost the first prize.

Again, in judging triplets of Teas two stands were nearly equal. but there was a bad triplet in each. In the first the triplet was certainly faulty, as it was stained and dirty; the doubtful triplet in the other was Jules Finger, and when one of my colleagues pronounced them the best, I objected that they were doubtful in shape, and livid and ugly in colour. "Yes," he replied, "but that is the nature of the beast," which I was constrained to admit is true. But ought we not to judge blooms as they are according to a standard of perfection, and to make no allowance for "the nature of the beast?"

On these two occasions I had the misfortune to differ from my brother judges, but at least I had the courage of my opinions, which is not always the case. At a cottagers' show held recently in a small village the Judges were Mr. A, head gardener at the big place with a fair staff under him; Mr. B, gardener in a smaller establishment, who has but one subordinate; and Mr. C, the "parson's man." All worked most harmoniously during the early part of the judging, Mr. A acting as teller, and finding his awards duly confirmed by the other two. At last Mr. C ventured to differ, and appealed to Mr. B, whose confirmations hitherto had been mostly mute ones. His answer was characteristic, I fear, of a not uncommon spirit at a small local show—"Oh! I always goes with Mr. A!" It was just as well perhaps, for A is a competent painstaking and, conscientious Judge, but it was "rough" upon C, who was evidently in a hopeless minority throughout, if he should venture to differ, and, but for the look of the thing, might as well have gone home at once.

I still find it a grievance, both as exhibitor and judge, that so much latitude is allowed as to the size of boxes and the distance between the blooms; and I still think it would be better and fairer for judges, exhibitors, and the public if there was to be one uniform size each for sixes, twelves, eighteens, and twenty-fours, and one agreed-upon distance between the blooms. A smaller distance might be allowed for Teas, and a uniform plan be adopted for triplets. I am bound to add that I can only call to mind one person whom I have overwhelmed by my arguments and induced to agree with me on this subject, and I believe he is neither an exhibitor nor a judge.

The practice of manipulating, or "dressing" Rose blooms for show is undoubtedly increasing, and has probably received additional impetus this year from the ungenial weather, which prevented the blooms from opening naturally. How far the practice may or may not be desirable is rather a difficult question. A purist, with no experience in the matter, would probably declaim against it at once, as a silly sacrilege, as bad as "painting the Lily." On further inquiry, however, he would probably find that an opening bud may be honestly, really, and naturally thus improved. The handle of a budding knife is the instrument generally used, though a pencil in certain hands is accustomed to work wonders. The great thing is to get the outside petals down. It is little use interfering with the inner ones except by blowing upon them.

I have said that an opening bud may be thus naturally improved. But it may also, if the expression is allowable, be unnaturally improved. There are certain Roses, of which Madame Willermoz is one of the most noticeable, with whom it is not natural that the outer petals should turn down. And I confess, though I am somewhat loth to do so, that I think it a defect in this Rose that the outer petals continue to stand up so straight, and that it seems to me an improvement, though certainly

not a natural one, when they are carefully and cleverly turned down. The outside petals are often stained and discoloured, while pure as snow within, and dressing would of course greatly improve the appearance in respect of colour and cleanness alone. I call to mind a triplet of Madame Willermoz at one of the principal shows this year, which, owing to extensive and audacious turning down of the outer petals, looked lovely against its weather-stained neighbours. But how far should this be allowed? for they certainly did not look like Madame Willermoz. The character of the Rose was entirely altered.

There are other Roses, such as Madame Eugène Verdier, H.P., of this shape, which I should call "semi-cupped" rather than "globular," with whom it is not natural that the outside petals should turn down: but because it is unnatural, I do not think it necessarily follows that it is no improvement. Florists think they can improve on Nature, and surely they very often do, by hybridising, training, and cultivation. However, the turning down of petals received a slight check at a country Rose Show this season. Two beautiful H.P.'s were being compared with each other by the Judges, in competition for the silver medal for best H.P. The owner of one of these Roses, which we will call a Reynolds Hole, was anxiously watching the proceedings from outside, through the open door of the tent. Great was his dismay when the Judge who held his Rose passed his other hand slowly and suspiciously up round it from beneath. Click! back when the creased-down petals like released springs, and Reynolds Hole and its owner were "shut up" together.

I do not, of course, mean that there was any deception on the part of the exhibitor, or that he had done anything wrong or underhanded. "They all do it," I do it myself. Competition is very keen, and, to be successful, the exhibitor must be like the two special coachman friends of the elder Mr. Weller—"up to all manner of games." It would be very difficult to legislate successfully against dressing, even if it were universally disapproved of. And yet I think if we were to come to have instruments for dressing Roses regularly figured and advertised, as is done for Dahlias and Chrysanthemums, we should feel a little shame. Where are we to draw the line?—W. R. RAILLEM.

RESTORING UNHEALTHY ROSES.

Is it ever worth while to attempt to restore an old and sickly Rose? I think not. I have often tried it, though not on Mr. Bardney's plan, and never have succeeded in doing more than galvanising them into life for a year or two. If the Rose grown generally shows signs of going off, I suppose there is nothing for it but shifting the whole stock to some virgin soil if you can get it; but if, as is usual in an old ground, only a few keep going back every year, my plan has been to dig up the old plant, making a large hole, and exchange the soil with a barrowload from the kitchen garden, and then plant either a good stock or a new plant. Even in the first case I am practically sure of a good young plant the next summer but one, while no plan could secure a good bloom earlier, and even then the plant would be an old one ready to slip through your fingers at an early day.—DUCKWING.

ROSES ON THE MANETTI STOCK AT NEWTOWNARDS.

MR. D. GILMOUR, JUN., and "S. S." seem (page 262) to entertain very incorrect views of my reference to Messrs. Dickson's Roses in my article descriptive of what I saw in their nurseries there less than a month ago, when having a holiday run in the North of Ireland and Scotland. I am not, I need hardly say, remotely interested in one Rose stock more than another, and I only attempted to describe what I saw, and what any visitor could see. I propose, like Mr. Gilmour, jun., to consult your space, and first briefly refer to his and "S. S.'s" notes, and then to make a few general observations. As to the latter, he says, "I long since came to the conclusion the Manetti is worse than useless, except for manufacturing yearly Roses; for if most Roses cannot live without it they will not live with it in many soils," and then he finishes a rather surprising sentence by saying in the last clause "some good Roses have gone out of cultivation chiefly through it," mentioning for illustration Olivier Delhomme and Marie Baumann. I must plead ignorance of Olivier Delhomme; and Marie Baumann, I am personally aware, has not gone out of cultivation, nor is the Manetti so "hateful to it" as he seems to think. What is meant by "manufacturing yearly Roses?" Is the insinuation that Rose growers bud on the Manetti purposely to last a year, and that a new stock must be purchased the following year if the Rose supply is to be maintained? I am justified in putting this construction on it, for your humorous correspondent, D. Gilmour, jun., says, "after the first year the growth and the blooms become small by degrees and beautifully less until death closes the painful scene!" and lest I, or any other benighted "Rose manufacturer, to last one year," should not be demolished by this poetic eutastrophe, he warningly intimates, "I could go on pitching into the Manetti over several sheets."

I am sure any reader who has been a careful student of his racy style and fertile imagination will take this readily for granted. I will dispose of my reference to the brief note of "S. S." by asking you to invite him to give an explanation to your Rose-loving readers who have not yet lost faith in the Manetti, of the seeming paradox—"If most Roses cannot live without the Manetti they cannot live with it in many soils." "Most Roses cannot live except budded on the Manetti!" What does Mr. Gilmour, jun., say to that? I never made so sweeping a statement.

For brevity I will finish my reference to that gentleman's note with "two facts and a prophecy." 1st, So far as I am aware, all the chief prizes carried away by nurserymen, and in numbers of cases by amateurs in the British Islands, were by Roses grown on Manetti stocks. At least, so I am informed; but I should like to see the opinions of others who have had greater facilities for forming a decided opinion. I can, however, speak definitely that this is true of Messrs. Dickson in Ireland and Scotland. Second fact. I want to know, would the nurserymen combine to disappoint their customers by continuing to grow and supply them with Roses that would practically last only one year? The insinuation is absurd, if not worse, the fact being that nurserymen conduct their business on very different principles. Mr. Gilmour, or others, admittedly may have a soil unsuited to the Manetti stock, but this never follows; therefore, "twenty years hence it will be unknown in the leading nurseries." Why, in my own experience, I can testify, though my collection is limited, I have Hybrid Perpetuals, Teas, and Bourbons, and a few Hybrid Teas planted out, and not even regularly lifted for seven or eight years, flowering regularly and still alive and robust on the Manetti stock, and so of many others I know. Most certainly thousands of the Roses I saw and referred to in Messrs. Alexander Dickson & Sons' nurseries at Newtownards were not huddled last year, nor seemingly for many years. I am sure Mr. Gilmour would concede to me the same right to "prophecy" he claims for himself. The Manetti stock has been in use for twenty years; it is still vigorous and popular both with nurserymen and their customers, and, borrowing Macaulay's idea, it is very likely to be so when the traveller from New Zealand takes his stand on London Bridge to sketch the ruins of St. Paul's.—W. J. MURPHY, *Clovelich*.

THE MANETTI STOCK.

I NOTE, page 262, that "D. G." takes very strong exception to the Manetti as a suitable stock for Roses, and I was somewhat surprised at the very emphatic manner in which he denounces it. I surely think "D. G." must have had inferior soil at his disposal or that his climate was bad. My experience with Roses huddled on the Manetti extends over many years, and is totally at variance with the statements made by "D. G." I have under my charge here several thousand Roses, and all, with the exception of Teas, are on Manetti stocks, and I can without egotism say it would be difficult to find healthier, freer flowering plants. Quite one-half of my plants are over twenty years old, and are still vigorous and healthy, while the blooms are of good quality. The soil is somewhat heavy, and the garden is within 200 yards of the sea.—JAMES RUSSELL, *Crawfordsburn Gardens*.

ROSE HOUSES.

THANKS for the fulfilment of Mr. Bardney's promise as to the recruiting of early forced Roses. In the Journal of May 17th last, Mr. Bardney, speaking of the height of houses for Rose-growing, says, "If the house was constructed specially for the production of blooms for market it would be much lower." Now, will Mr. Bardney kindly say what width of house and what height he would advise for a house for growing early Roses for market? When he speaks of a house being much lower if specially made for growing Roses for market does he mean the "pitch" would be less, or merely that the side lights would be lower, the eaves coming nearly down to the ground? If it would be at all interesting to the readers of our Journal, I have pretty largely grown the new Roses of this and last year, and could give some reliable account of them.—S. S.

[No doubt many of our readers would be interested in any remarks our correspondent favours us with on the subject named.]

RENOVATING FRUIT TREES.

IN the course of our duties we must not only attend to fruit trees in a state of prosperity, but those of a less fortunate character. The gardener's vocation somewhat resembles the physician's in this respect; he is called upon to control the exuberant, to assist the weak, and to renew, as far as possible, the shattered constitution; and, to carry the parallel still farther, to perform surgical operations where necessary. Very many fruit trees, especially in the ordinary orchard, perish, or fall into a state of premature vegetable decrepitude, for want of a little assistance rendered in time. The renewal of the vigour of trees thus situated has often been referred to, but the remarks have been principally confined to branch-pruning. We will now proceed to show that much may be done at the root; and in our opinion the end of September is the most eligible time for the operation. Matters of this kind constitute a sort of extra in gardening affairs; no man of any standing in our profession will leave any of these extras until spring if he can possibly avoid it. Spring in these days comes laden with a burden peculiarly its own; a burden which it is scarcely capable of sustaining. Spring will do well, then, to borrow a few hours from sober-faced and lightly laden autumn. Borrow, did we say? it must be stolen—shame to say so; it will never be repaid.

Not only is this good with regard to the case in hand as an expedient, but in our opinion the practice is right in principle. If early autumn planting is right in the majority of cases; if the putting out cuttings of many deciduous trees is right; why then this is right, and for the very same reasons. The process is thus

set forth in Lindley's "The Theory of Horticulture." "As soon as a plant has shed its leaves it is as much at rest for the season as it will be at any subsequent period; indeed, it is greater at that time, because its excitability is completely exhausted by the season of growth; and it has had no time to recover it. If at that time a root is wounded a process of granulation or cicatrisation will commence, just as it does in cuttings, and from that granulation, which is a mere development of the horizontal cellular system, roots will eventually proceed." Here, then, are arguments of a scientific character, backed by the phenomena of everyday occurrence. So then it will be seen that a granular process takes place in cuttings, technically termed a callus, and this callus is the producer of fibres. This will serve to throw light on the process which occurs when roots are cut, as in the act of transplanting or root-pruning. Such injuries, then, if they must be inflicted, had best be perpetuated early in the autumn, inasmuch as the trees have a longer period to recruit in; and if the process take place in the end of September granulations, if not actual fibres, will be produced by the coming spring; Nature is latently making efforts, slowly but surely, to repair these damages. Injuries arising from late spring planting, as to fruit trees, are very frequently productive of serious aggressions on the part of the insect tribes. Amongst these, the red spider and the aphides hold a conspicuous position; also the scale family, or those bearing the generic title Coccus. Having thus paved the way to a recommendation of an early procedure in these matters we will examine cases.

Many trees are to be met with in all quarters failing betimes, and evidently not through age alone, neither through what is termed canker; for although the extreme points of many fruit trees are apt to shrivel and die away, especially ordinary orchard trees, yet on examination it will be found that such is not in general the disease termed canker. Since ordinary orchard trees, then, are more liable to be thus conditioned than those on prepared soils in our kitchen gardens, how is it? Why, because the majority of our orchard trees have free liberty to range in ungenial subsoils. From the subsoil, in the main—whether as being too retentive of chilling moisture, or from the presence of deleterious matter—proceeds most of the evils we have pointed to; and such suggested to us, some years since, the general adoption of artificial substrata and the planting on higher levels.

The wearing-out or weak trees alluded to, after their lower roots become paralysed or lost, are driven to seek sustenance by means of the surface fibres alone; and as all that portion next the tree has been long robbed of its fertility, the very exterior points alone are the only active agents; and it is principally to these that we apply renovating materials. Where it is intended to carry out this renovating process a heap of compost must of course be provided. A good sound loamy turf is the principal thing to obtain; and those who cannot obtain it should get some turfy material of some kind as part of the compost. One portion of this, one of old manure, and a third of half-decayed litter of any kind, leaves, &c., well chopped and mixed, will make a good compost. If plenty of a good sound garden soil of a rich character be at hand the mass may receive nearly a half of it.

In commencing operations with a tree thus situated—say an orchard Apple tree, with a trunk of 6 or 8 inches diameter and a head corresponding—let the operator draw a circle around it with a trammel about 7 feet from the bole; this constitutes, in the main, the boundary line inwards of his operations, and serves to keep the spade from unwarrantable liberties. The operator may now proceed to dig a trench two spades in width all round the tree; and in the course of his work he must take especial notice where the principal horizontal roots are, and where there is a comparative absence of them; in the former case politely giving way, notwithstanding his circle, and in the latter advancing towards the bole of the tree.

After excavating this one spit deep all round he must proceed to take a second spit, or enough to gain quite half a yard in depth; and if this second spit is an inferior material it must be wheeled on one side by itself. This done as before the operator will now know on which side of the tree the least roots are, and at that position he must bore for the tap roots—that is to say, he must dig under the tree, and endeavour, without disturbing it too much, to cut all deep-descending and ill-looking roots away, filling the hole beneath full of weeds or any refuse stuff from the rubbish yard. This will induce some fresh fibres in due time, for there need be no further fear of tap-roots; and now he may go round and fill in his trench, cramming lumps of turf and manure into every crevice within the circle, and where, through the absence of roots, the spade has made extra advances. If the compost is tolerably dry, which it ought to be, he may tread it slightly as he proceeds. The whole being filled in, and we ought to have said the wounded roots all cut with a sharp knife, the surface of the interior of the circle may be eased of all the loose soil thereon and a coating of the same dressing

applied—equal in bulk to that removed—and finally 4 inches of good half-decayed manure cased all over the surface; and thenceforth no footsteps should be permitted until the whole has settled.

In the middle of November we would put the trees under a course of pruning, using the knife rather severely, especially in thinning out. All decaying stumps of course must be removed, and the whole of the tree scraped and cleaned thoroughly, extirpating both moss and insects. Whilst this is being done boards should be laid beneath to tread on, for if the mulching is "puddled" the previous operation will be nullified. However, if frosty, there will be occasion for it. As soon as pruned the whole may receive a thorough soaking with dunghill water. Trees thus treated will, in the majority of cases, recover much of the freshness of youth within a couple of years.—N.

MR. VINER ELLIS sends the following note relative to the origin of the VICTORIA PLUM:—"In the 'Fruit Manual,' fourth edition, it is said to be a Sussex Plum, but I would suggest another origin for it. It has grown here certainly longer than I can remember (seventy years) under the name of Dolphin (a corruption I presume of 'Dauphin.') The introduction of the Plum as far as I can remember was in this way. At first the tree was limited to the fronts of the houses of the owners of small vessels (sloops) navigating the Severn to ports in the Bristol Channel, and conveying fruit and merchandise to and from those ports. From those houses it spread higher up the river and farther inland until this parish and other parishes were stocked and the tree was planted as a standard. Now it appears to me as most probable that from the intercourse with the foreigner (Frenchmen) at the Channel ports, the introduction of the Dolphin (Dauphin) and of the Prune into this district on the banks of the Severn was due."

— WE learn with regret that MR. W. COURT of Messrs. J. Veitch and Sons, Chelsea nursery, died rather suddenly on the 17th inst. Mr. Court was well known as a skilful propagator, and has performed good service in the hybridisation of the Sarracenias and Nepenthes, one of the latter being named in his honour. He frequently visited the United States as a representative of the firm, and his quiet, genial, but business-like manner gained him general esteem. He was forty-five years of age, and had been ailing slightly for some time.

— A CORRESPONDENT writes:—"As already announced, after thirty years, Mr. John Wilson has resigned the secretaryship of the YORK GALA, and Mr. Charles Simmonds is appointed his successor. Mr. Wilson will carry with him the esteem and regard of every exhibitor, judge, and others officially engaged at the Gala during the above period. It has been a wonderful horticultural exhibition, and attracted horticulturists from all parts, the usual annual expenses being about £1500. Always watchful for the progress of the Gala, he during the last twenty-five years obtained upwards of £550 from nurserymen, horticulturists, and other friends, besides the medals awarded by the Trustees of the Veitch and Turner Memorial Funds, as also contributing £35 from his own pocket. A Committee of influential gentlemen in the city will still guide the affairs of the Society, and the business will be carried on at the old address. Mr. Wilson gives up his position whilst the Society is in the zenith of its fame, with an invested fund of £1725 to provide against reverses. It is the intention of the York Committee to present Mr. Wilson with a handsome silver salver, and many of the exhibitors and other friends also contemplate a souvenir of their esteem and regard."

— MR. G. SILVER, Wroxall Abbey Gardens, near Warwick, sends the following note:—"We had a very REMARKABLE OCCURRENCE here on Monday afternoon, the 24th inst., and I think worth recording. About midday the air began to thicken from the north, and at one o'clock we were enveloped in a cloud of black flies. Millions of these little creatures were to be seen, and the ground is strewn with them, giving it quite a black appearance. Some Callas that I had taken from the ground in the morning and potted were stood out in a shower of rain. We can now scarcely see what they are, they are black with flies. Vegetation of all kinds is also covered with them. I should imagine that this is in some way accounted for by the early departure of the

swallows from this neighbourhood, as there appear to be only a few young ones left."

— THE REV. W. W. WINGFIELD, Gulval Vicarage, Penzance, writes:—"Can any of your correspondents inform me as to the rarity or otherwise of ARAUCARIA IMBRICATA PRODUCING CONES IN ENGLAND? It has done so in this parish this year, some ten cones being on one tree out of about twenty-five planted together in 1888. The cone-bearing tree has its laterals in closer more compact growth than the others."

— THE "KEW BULLETIN" FOR SEPTEMBER continues the reports on colonial fruits, a long and interesting account of the fruits of Dominica being contributed by Dr. H. A. Alford Nichol's. Shorter reports on Montserrat, St. Christopher and Nevis, Virgin Islands, and Bermuda are also good. A chapter on Indiarubber in Upper Burma contains some useful information.

— EUPHARIS GRANDIFLORA.—Mr. Record has found out what we Orchid collectors know from experience—i.e., that tropical bulbs and plants have a resting and growing season corresponding with the dry and rainy seasons in their own country. I was once in the island of St. Lucia, and saw Amaryllis equestris in flower, but the ground was so hard that I broke several negro's hoes in trying to get up some bulbs, and eventually had to rely upon a cutlass, used for cutting sugarcane, to get them up, therefore it seems as well that Eupharis grandiflora should be rootbound and given a resting season. In the tropics the rains are very abundant for a time, so he will be right in giving a liberal treatment at the proper season. Although the Eupharis before mentioned is supposed to come from the river Amazon district, I am not aware that modern travellers have ever found its habitat, or that any record is to be found that it came from there except the name, but it is without doubt of South American origin. These few hints may be of value to bulb growers. The thing is not to rely entirely upon what other growers do, but to try and find the conditions they grow under in their own native homes, and adopt as nearly similar a *modus operandi* as possible.—WINTON.

— LIFTING POTATOES.—We feared from the premature decay of the haulms of early and second early varieties that if the unfavourable weather continued the tubers would be badly diseased. This I am sorry to say is their condition, and we shall not be able to save many for seed from those that are now being lifted. Large quantities of the tubers appear to be sound, but when they are cut in two they are black in the centre. The majority are in this condition, and in a very short time they will all decay. Potatoes, since kidney varieties were practically over, have been very cheap, only realising from 1s. 6d. to 2s. a cwt. They were cheap the whole of last year, but the reverse this winter will probably be the case unless the late crops escape; and it is scarcely possible that they can, for the bad weather which we experienced through June and July has continued in the north of England with no prospect of a change at present.—W. B.

— ONCE more have TUBEROUS BEGONIAS substantiated their claim to be regarded as excellent bedding plants. A season like the present is a severe test to any plants employed in the flower garden. Those found to bear the test should be encouraged. The advantage Tuberous Begonias possess over most bedding plants is that they progress in any season be it either very wet or very dry, assuming, of course, they are treated in a rational manner at the commencement of the season. When grown under the cool system the plants at once commence flowering, and continue until frost cuts them down. Wet weather seems to suit them, ours have done quite as well this season as in any past year. I am convinced that many people ruin their chances of success by pushing on the plants in heat, thus rendering them soft and unable to withstand extremes of either heat or cold, wet or dry.—M.

— BLENHEIM ORANGE AND HERO OF LOCKINGE MELONS.—I can fully endorse Mr. Iggulden's remarks on the above excellent Melons in last week's Journal, page 266, as I grow both varieties pretty extensively, both in low, well-heated, span-roof houses, and in cold pits. Both Blenheim Orange and Hero of Lockinge are very handsome as well as first-rate Melons when well grown. I showed one fruit of each in my first prize collection of fruit at Brighton on the 12th inst. The Blenheim Orange weighed just upon 7 lbs., and the Lockinge 5 lbs., both fruits being beautifully netted and highly coloured. I have several more fruits of the same dimensions ripe and ripening. I tried very hard, but failed, to have some of these fruit ripe a week earlier. We grow our Melons in a good yellow loam, to which a fifth part of lime rubble is added, giving occasional surface-dressings of Beeson's

manure before giving water at the roots when the fruits are swelling, as well as liberal waterings of tepid liquid manure between the said dressings, avoiding wetting the soil immediately round the stems of the plants in doing so.—H. W. WARD.

— REFERRING to PEA VEITCH'S AUTOCRAT, "W. I." remarks :—"We find this comparatively new variety very productive at the present time, and are of opinion it will prove one of the best for the late crops. It attains a height of about 4 feet, is of branching habit, and yields abundance of handsome pods well filled with green and very tender Peas. Autocrat will be extensively cultivated long after many much-lauded varieties are 'things of the past,' at least such is my impression."

— THE same correspondent commends the TURNIP-ROOTED BEET, CARTER'S CRIMSON BALL, observing :—"The ordinary Turnip-rooted Beet is much too coarse this season, a great per-centage of the roots being of no service for salads. Not so the new form under notice, and once more it has demonstrated its superiority. At least 90 per cent. of the roots are richly coloured, and all are tender and sweet when cooked."

— "B." writes : "At Messrs. R. P. Ker & Sons, Aigburth Nurseries, ACHIMENES GLOXINIAEFLORE was recently noticeable with its light faintly spotted flowers, but a variety of this form distinguished as aurea was a decided acquisition. The flower was much the same as the former, but more than double its size, with a blotch of rich orange in the throat. It is decidedly the finest form of Achimenes that I have yet seen. If it proves a good grower and profuse flowerer it will before long become a general favourite."

— "In the same nursery THE CROTONS are magnificent, and it is questionable if they could be surpassed. The house is narrow, with no central stage, and only a narrow one on the sides. The side lights are at least 4 feet high, while the roof is very flat. Houses with a sharp pitch do not find favour in these nurseries; in fact in all recent constructions they are reverting to the old-fashioned plan, as the houses are strikingly flat in the roof. Whatever might be urged in favour of houses with sharp-pitched roofs, the fact that plants do well in these flat-roofed houses cannot be overlooked. The former are certainly good for one thing if for nothing else, and that is to tax the ingenuity of those in charge, in order to bring plants within reasonable distance of the glass."

— AGAPANTHUS UMBELLATUS ALBUS.—The blue form of the good old Agapanthus is common, but is not nearly so valuable as the white variety. The latter was extensively shown at the late Bath Show by Messrs. R. Veitch & Son of Exeter, and many visitors were much struck with its value, and it ought to become popular, especially where pure white cut flowers are in demand. It is equally as easily grown as the old A. umbellatus, and the single flowers may be detached and effectively used in buttonholes, bouquets, wreaths, and crosses. As a rule good white flowers are not very plentiful late in August and early in September, and the white Agapanthus is a welcome addition to the list.

— ONE of the best border plants this season is BOCCONIA CORDATA. Its bold foliage, deep green on the upper surface and ashy grey beneath, has developed thoroughly under the influence of much rain, while its stems have perfected fine spikes of bloom at a height of 7 feet in some instances. In no position has it shown to more advantage than in beds of Rhododendrons in open positions. If the largest spikes are considered too large for decoration when cut the side spikes are not; indeed, we find them useful for mixing with other border flowers. The Bocconia increases by division of the roots; in fact every piece of root 2 or 3 inches long sends up vigorous growths, which quickly assume large proportions if planted in any moderate soil.—B. W.

— COREOPSIS DRUMMONDI.—What a beautiful annual this is! I do not think it is nearly so much appreciated as it should be. Planted in beds or in clumps in mixed borders it has a very telling effect. I consider it by far the best variety of any of the Coreopses. Its bright golden yellow flowers when cut last in water for eight or ten days, and the profusion of flowers obtained from a small bed enables one to make the most of the space at command. We have used it on several occasions arranged with the red-tinged plumes on Rhus Cotinus for the dinner table, and on every occasion it has been greatly admired. Owing to the wet summer this year the plants have grown taller than usual, and the flowers have been exceptionally large and well coloured.—G. T. SILVER.

— IN spite of the wet and cold summer STENACTIS SPECIOSA has done remarkably well this year. With us it commenced flowering the second week in July, and has continued up to now. The flowers are useful for cutting, being light, and remain fresh some time. Light blue flowers are not too plentiful, therefore this Stenactis is all the more prized. A stock is easily obtained by dividing the old stool in the autumn; every piece having a root will make a good plant, and flower the next season if it has the protection of a cold frame during the winter, planting from these during April. This is a good method if a large stock is required in a short time, otherwise dividing the roots into pieces 4 inches square, planting at once in the borders, answers very well.—S. P.

— "E." commends LOBELIA CARDINALIS as a capital plant for a wet season. "Here in a bed is a mass of about four dozen plants that have grown 4 feet high, and each bears a fine spike of bloom, which viewed from a distance even is most effective. Under a close inspection the brilliant cardinal-coloured flowers are always appreciated. The rich dark-coloured leaves add to its beauty, which is enhanced by a carpet of Antennaria tomentosa covering the ground, and making a capital contrast with the Lobelias. In a season like the present it is well to make note of this plant doing such good service when other flowering plants have run to leaves. When a stock of plants is obtained of the true sort they are preferable to those obtained from seed, which vary so much in the foliage that uniformity of growth and colour is not nearly so good. Therefore we increase the stock by dividing such as are of the true type."

SCHOMBURGHKIAS.

THIS genus of Orchids is a remarkable one. The plants have much the appearance of some giant species of Cattleya, but this particular species resembles the noble Lælia superbiens, and when not in flower it requires a well-practised eye to detect the difference. When in flower the veriest tyro in Orchid culture would perceive they were two distinct species. We have long, however, suspected that the Lælia is a sort of stepping-stone between the two genera, and might, without any far-fetched or deeply studied character, be transferred to the family now under notice. The flowers of the Lælia are produced on very long flower stems, and are arranged in a close panicle at the end, exactly in a similar way to those of S. crispa.

S. CRISPA.—This has large pseudo-bulbs, with two or sometimes three long, rather thin, leaves on the summit. The flowers are produced on stems frequently 5 or 6 feet long, on a short panicle; they are of a brownish yellow, much crisped or curled at the edges; the lip is white, striped with pink, and edged with pale yellow. Each flower is large, measuring 2½ inches across. It has a slight perfume.

S. MARGINATA; Surinam. The pseudo-bulbs of this species are shorter and thicker than the preceding. The flowers are of a deep orange, shaded with red; the lip is pale lilac; the whole flower is margined or bordered with brownish-red—hence its specific name. This is a truly fine plant. It is sold in the markets of the West India Islands under the name of the "Spread Eagle," from a fanciful miniature resemblance of the flower to that noble bird. The flowers are handsome, and produced on somewhat shorter stems than S. crispa. This plant is well deserving of cultivation in medium-sized or large collections.

S. TIBICINIS; Honduras. The pseudo-bulbs of this species are rather remarkable; they are hollow when old, and blunt at the apex. The natives cut them off, and form them so as to be able to blow through them, and produce a noise like the horns of a cow when blown through; hence they call it the Cow-horn Orchid. This species has the longest flower stems, frequently from 8 to 9 feet; they are of a deep pink colour, spotted with white on the outside, and with rich brown-red inside. The lip is white in the centre, rose colour at the sides. It has a lobe in the middle of a fine bronzy-red colour. Like all the genus, the flower springs from the top of the last-formed pseudo-bulb, and generally flowers about the month of June. Equally handsome, and worthy of cultivation with the rest of the genus.

S. UNDULATA; La Guayra.—This, very possibly, is but a variety of S. crispa. It is sometimes named S. violacea from the deep colour of the flowers. Sepals and petals of a light purple, waved

or curled at the edges; lip violet-coloured; flowers much larger than those of *S. crispa*. Flower stems 8 or 9 feet long.

CULTURE.—While these plants are young, newly imported, or in a sickly state, they should be grown on blocks of wood; but when they produce plenty of roots in the air, and have made middling-sized pseudo-bulbs, they should be potted. The best plants we ever saw were grown in broken crocks. The pots were wider than usual at the top, and the plants were set as it were in the midst of the crocks, care being taken that the buds at the base of the pseudo-bulbs were left uncovered. The roots were running about on the surface and amongst the crocks quite freely and healthily, and the pseudo-bulbs appeared to grow stronger and stronger each successive season, the plants had flowered and appeared to be quite happy and at home. We are trying this somewhat novel compost, and our plants are evidently improving. Yet we do not entirely depend upon this method, for we remember a friend tried growing Orchids of all kinds in crocks and found it did not answer. Therefore we grow part of our stock in a compost of very fibrous peat, half-decayed leaves, chopped sphagnum, broken pots and charcoal, all mixed together, draining extra well, and raising the plants up on a hillock in the centre of the pots on the compost, securing them well till they get established with stoutish sticks. These precautions are taken to prevent the roots from rotting at the ends, which they are very apt to do if cultivated in a careless or common way. They will grow on blocks best, but in that way do not obtain sufficient nutriment to produce large pseudo-bulbs, without which they will not produce flowers. As they are natives of warm climates they require great heat when growing, even as high as 80° to 85° by day and 75° by night; but when at rest 10° or 15° lower will be sufficient.—ORCHID GROWER.

THE PERSHORE PLUM.

ON page 246 mention is made of our old and valuable friend the Pershore Plum, and it is stated that Gisborne's is more prolific than the Pershore. This we Pershore people deny *in toto*. We can point to a plantation of say 20 acres of Pershores; and we will venture to assert that our 20 acres will produce more fruit than 30 acres of Gisborne's. One friend of mine in this district has sent nearly 2000 pots of Pershores away this year at 5s. per pot of 72 lbs. net, and we have been known to send from our small station 100 tons of fruit in one day. We do not say ours is good for dessert, but we do say it is one of the very best grown for preserving (I have sent you a few to test them). The trees throw up suckers very freely. They are dug up, planted out about 5 yards apart, and they begin to bear directly (no grafting required). But there is one thing we are certain of, and that is that they do not thrive and bear so well out of this district, taking an area of say seven or eight miles. We send hundreds away every year in the shape of stocks to all parts, but they do best by far in this locality. We find Rivers' Early Prolific, the Pershore, and the Victoria the most profitable sorts. Four growers in this immediate neighbourhood this year (and it is only a partial crop) will send away from four to four and a half thousand pots of Pershores.—J. W., *Pershore*.

[The Plums received are much larger than any sample of Gisborne's we have seen this year.]

POTATOES.

IN reply to a recent query about Potatoes, the earlier sorts were much smaller than usual, but quality good. Snowdrop has been admitted as a standard variety. Not quite so early as Myatt's, it is a better cropper, and the quality is quite as good. Early Puritan promises well, and Sutton's Early Market as a good round will be again tried. The only sorts left in the ground were two new late varieties on trial and White Don for everyday use. These latter are badly smitten with disease. I hear the disease has attacked second early sorts all round. In fields the haulm of ripening Potatoes is very badly blackened. This, of course, is mainly on light soils, where growth was made early in the season. On heavy soils the Regents have grown very badly on account of the wet condition of the land. Good weather for the past week will make up for late kinds, which are sure to be a fair crop. As a grower said to me the other day, there will be no Potatoes at 10s. per ton this season. The crop all over will be fairly good, but not so overwhelmingly plentiful as last year, and the disease will help to keep prices up.—B.

ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 25TH.

DAHLIAS were excellently represented at last Tuesday's meeting in the Westminster Drill Hall, numerous large collections of blooms being staged both by nurserymen and amateurs. Show, Fancy Pompon, single and Cactus varieties were included, the selections in most cases also comprising promising novelties. It would scarcely have been thought possible that as many as sixteen could be found worthy of certificates, but this was the number the Floral Committee awarded, and it may be presumed that the members were in a particularly happy and generous frame of mind, for they are seldom so liberal. As a show of cut flowers

it was admirable, but the weather was very unfavourable, and the attendance of visitors consequently small.

FRUIT COMMITTEE.—Present: John Lee, Esq., in the chair, and Messrs. J. Smith, G. W. Cummins, J. Cheal, T. J. Saltmarsh, R. D. Blackmore, W. Marshall, S. Ford, Harrison Weir, P. Crowley, P. Barr, and T. B. Haywood.

Mr. G. H. Richards, Somerley Gardens, Ringwood, Hants, exhibited an unusually fine fruit of a Queen Pine, massive, deep, well-proportioned, and weighing 7 lbs. 6½ ozs. A cultural commendation was awarded. Mr. P. W. Fairgrieve, Dunkeld Gardens, N.B., sent a collection of Peaches and Nectarines, Hale's Early and Early York being the best of the former, with Cox's Emperor, Lawson's Golden Gage, Pond's Seedling, and Imperial Gage amongst the Plums. Messrs. Hurst and Son, 152, Houndsditch, sent a "hybrid Cucumber," said to be the result of a cross between Telegraph and Blue Gown, the fruits large, smooth, and dark green. Mr. W. Roupell sent fruits of Criterion Tomatoes, Mr. R. Dean sent a dessert Apple with a Russian-like title, and Messrs. J. Veitch & Sons, Chelsea, had an interesting collection of Apples, Pears, and Plums (silver Banksian medal).

A first-class certificate was awarded for *Melon Glenhurst Perfection* (C. J. Waite), a green flesh variety of excellent flavour, neat globular shape, moderate size, and well netted.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. W. Bates, H. Herbst, W. Wilks, T. Baines, R. Dean, B. Wynne, J. Dominy, H. M. Pollett, J. O'Brien, W. Holmes, E. Hill, G. Duffield, W. Goldring, J. Walker, W. H. Lowe, and J. Fraser.

Apart from the Dahlias the most interesting exhibit was a grand group of Nerine Fothergilli major from Baron Schröder, The Dell, Egham (gardener, Mr. Ballantine). The plants were of various sizes, from small bulbs in 48-size pots to veteran clumps of numerous large bulbs, and they bore a total of about 250 trusses containing ten to thirteen flowers each. The variety is one of the finest grown, both in the size of the flowers and truss, breadth of the petals, and brightness of colour, though the latter character was not seen to good advantage at Westminster owing to an unsuitable background in a leaden-tinted wall. Adiantums were, however, employed as a margin, and imparted a fresh pleasing finish to what was undoubtedly the finest group of Nerines exhibited in London, amply meriting the silver Banksian medal awarded by the Committee. At The Dell these plants are grown throughout the season in a lean-to frame facing the south, being only removed when they are flowering to be arranged in the houses. They receive a good roasting and thorough resting, are frequently supplied with liquid manure where growing and flowering, but they are only re-potted every three or four years, and very little manure is used in the sandy loam employed as soil. The illustration (fig. 32) on the next page well represents the characters of this Nerine.

F. G. Tautz, Esq., Studley House, Hammersmith (gardener, Mr. J. C. Cowley), exhibited a plant of *Cyanoche chlorochilum*, with large peculiarly formed greenish flowers (cultural commendation). G. F. Wilson, Esq., brought some flowers of *Lilium auratum* and *lanefolium*, cut from the open ground at Oakwood Grange, Weybridge. W. Keith, Esq., Cornwallis, Brentwood (gardener, Mr. J. T. West), contributed a handsome collection of Dahlias, representing all the types, for which a bronze Banksian medal was awarded, an inadequate recognition of so fine an amateur exhibit. Mr. G. Ford, Leonardslee Gardens, Horsham, showed some remarkably beautiful *Celosias*, fine plume-like trusses of most varied tints, gold, red and crimson predominating. The strain was highly commended.

The nurserymen's exhibits occupied the greater portion of the space, several contributions of an important character being staged. Messrs. Paul & Son, Waltham Cross, had eight boxes of H.P. and Tea Roses, all fresh, bright, and extremely good for such a late period. Freely flowered wreath-like stems of *Lapagerias rosea* and *alba* also came from the same firm (bronze Banksian medal). Mr. T. S. Ware, Tottenham, had his customary charming collection of hardy flowers, comprising Shirley Poppies, Gaillardias, Lilies, Geums, Asters, and several novelties, besides Dahlias (silver Banksian medal). Messrs. J. Veitch & Sons, Chelsea, sent a group of plants, including a neat little shrub, *Berberis Thunbergii*, having abundant bright red berries, fine trusses of *Hydrangea paniculata grandiflora*, specimens of *Crataegus pyracantha Lalindei*, with trusses of the numerous varied greenhouse *Rhododendrons* (silver Banksian medal).

A wonderfully fine group of *Nepenthes* from Mr. B. S. Williams, Upper Holloway, gained the exhibitor a silver-gilt Banksian medal, and very rarely is such a choice collection of these interesting plants exhibited. Most of the distinct species, varieties, and hybrids were shown, the plants fine healthy specimens bearing numerous well-developed pitchers.

The Dahlias were extremely fine, and so many varieties were shown that we have not space this week for even a selection, but nearly all sections were shown well, quite rivalling the National Dahlia Exhibition in quality of blooms of the Show, Fancy, Pompon, and "Cactus" types especially, the singles being in the majority. The exhibitors of Dahlias were Mr. C. Turner, Slough, Messrs. Paul & Son, Cheshunt, who also had a group of hardy flowers (silver Banksian medal), Messrs. Keynes, Williams & Co., Salisbury (silver Banksian medal), and Mr. G. Humphries, Chippenham (bronze Banksian medal). Messrs. H. Cannell & Sons, Swanley, had an attractive group of Cannas, Begonias, and Dahlias (silver Banksian medal). From Chiswick came a group of Liliput Asters, very neat and pretty; Mr. W. Baylor Hartland, Cork, sent flowers of *Helianthus multiflorus plenus*; Mr. R. Dean some fine Pentstemons (vote of thanks); and Mr. G. Stevens, Putney, fine blooms of *Chrysanthemums* Mr. Wellams and C. Wagstaff.

CERTIFICATED PLANTS.

Dahlia Mand (Turner).—This and the following one are show varieties, raised by Mr. Fellowes but shown by Mr. Turner, both handsome varieties. The above named has large, handsomely built deep blooms, of a delicate mauve tint, and white centre. *Agnes*, a rich

Mathew Campbell, yellow and orange, streaked crimson; *Panthea*, a Cactus variety, with bright reddish salmon-coloured flowers; *Honoria*, of a similar type, rich clear yellow.

Nerine excellens (T. S. Ware).—A graceful bulbous plant, with bright, rosy, narrow, undulated petals, and darker mid veins.

FIG. 32.—NERINE FOTHERGILLI MAJOR.

clear yellow variety, the bloom of excellent shape, deep and symmetrical. *John Cooper* (Humphreys).

Pompon Dahlias (Turner).—*Juliette*, bright orange, neat; *Admiration*, maroon tipped white; *Vivid*, light scarlet, pretty; *Lothair*, scarlet, with a yellow centre.

Pompon Dahlia (Keynes, Williams & Co.).—*Isabel*, bright yellow, tipped bronze; *Little Darkie*, deep maroon, a neat compact bloom;

Lilium Wallichianum (T. S. Ware).—The flower of the Lily is somewhat like a small *L. auratum*, white, with a yellowish centre, about 5 inches in diameter; the leaves linear and short.

Aster Townsendi (T. S. Ware).—A bold variety, with broad flower heads, deep purplish blue, and a yellow centre, bushy, compact, and free.

Harpallium rigidum semiplenum (T. S. Ware).—A semi-double variety of this useful autumn flowering plant, bright golden yellow.

Canna Geoffrey St. Hilaire (J. Veitch & Sons).—Foliage dark red, flowers very large and brilliant scarlet, very effective.

Ornamental Beet McGrigor's Favourite (B. S. Williams).—Certificated as a decorative plant, leaves narrow, tapering, and deep red.

Canna Paul Bert (Cannell & Sons).—A handsome variety, with large, bold, orange red flowers.

neglected plants to which cultivators might advantageously devote some consideration. At least two are old inhabitants of British gardens, though they are now seldom seen except in a few establishments where rarities are prized. One of these is *S. virginica*, which seems to have been known in the middle of the eighteenth century, but it was not brought

FIG. 33.—STUARTIA PSEUDO-CAMELLIA.

STUARTIAS.

So little diversity is introduced into shrubberies as a rule, that there is always ample excuse for calling attention to species adapted for planting either in them or as isolated specimens on lawns. The Stuartias are not numerous, and they come within the rather long list of

into prominent notice until it was figured in "Andrews' Repository" in 1804 under the name of *Stewartia marilandica*. *S. pentagyna* is another North American species which was cultivated at Kew before 1785, and has been described under the now discarded name of *Malachodendron ovatum*. Both these have large white or creamy white flowers, with rich green ovate leaves, and constitute really handsome

shrubs that when in flower are scarcely rivalled by any other occupants. A beautiful addition has within recent years been made to this interesting genus in the species *S. pseudo-Camellia*, a native of Japan, whence it was introduced by Messrs. J. Veitch & Sons of Chelsea. Plants have been established at Coombe Wood, where they have proved quite hardy, like the American forms, and the flowering specimens shown a few weeks ago at the Royal Horticultural Society's meeting at Westminster received the recognition of the Floral Committee in the shape of a first-class certificate. From these examples the woodcut (fig. 33) was prepared, showing the flower and foliage forms.

All are deciduous shrubs which succeed in ordinary good garden soil, not appearing very particular as to situation, though a moderately sunny position suits them the best.

GRAPES SCALDING.

I SHOULD like to see a few more gardeners' opinion on this question. If other varieties of Grapes will scald equally as much as Lady Downe's if subjected to the same conditions, why is it that Lady Downe's will scald and the others not when grown in the same house? I consider that scalding is peculiar to Lady Downe's, but that it can be prevented by those in charge, and that the conditions which will scald Lady Downe's will not scald the Black Hamburgh or any other variety. Surely my views are not singular, and I am under the impression that 99 per cent. of gardeners will endorse my opinion. Mr. Simpson takes exception to my statement in not having a "fixed temperature." Now I maintain that it is having this fixed temperature that is the root of the evil. Often on a warm "muggy" morning the temperature of a vinery is higher without heat in the pipes than on a cooler morning with much heat in the pipes. My advice to all young men who wish to prevent scalding with Lady Downe's Grapes is to keep a comfortable warmth in the pipes during the night, with a circulation of air, and this increased as soon as it is seen that the sun would soon raise the temperature. The temperature about the Vines near the roof is always much higher when the sun is shining than in the body of the house where the thermometer is usually kept, and when fixed temperatures are adhered to the foliage is "stewing" when the thermometer down below does not register the desired point.

In answer to Mr. Bardney's remarks on page 260, I will refer him to his original article at page 162, so as to keep him to the point in question. In that article he says that "it is no more difficult to scald the berries of Black Hamburgh and Madresfield Court than those of Lady Downe's," a statement which I say Mr. Bardney cannot substantiate, and how any gardener with any practical experience in Grape-growing can make such a statement I am at a loss to understand. As Mr. Riding says "it would require gross carelessness to accomplish such a feat," whatever the structures are like. I had the management of five vineries for three years, with not one top or bottom light moveable, air being admitted by small ventilators in the back wall, and in these vineries I never saw a scalded berry of Black Hamburgh, Muscat of Alexandria, or West's St. Peter's, but on this latter Vine a Lady Downe's was grafted, but it used to scald, but very slightly. The ventilator over this Vine used to be kept open, but the heating was defective. A "chink" of air in a corner of a vinery I should be sorry to leave as the only precaution and a safeguard from scalding. The ordinary precautions I use in Grape-growing is common sense practice, which any gardener would use if he required good Grapes to place on his employer's table. We are more quickly on the alert with the ventilation in the Lady Downe's house than with the others, but these we do not neglect whatever the time of year or season may be, which is merely to keep the Vines in health and vigour.

Mr. Bardney also takes exception to my statement about moisture condensing on the berries. What causes moisture to condense on the berries? Why an overheated atmosphere, caused by the sun shining suddenly on the house without sufficient ventilation, as well as insufficient heat in the pipes to prevent the berries becoming cold. Allow the above to happen, and you will soon have Lady Downe's scalded. A fair warmth in the pipes at night with sufficient ventilation will prevent this. Full bunches of Lady Downe's are more profitable than pieces. I am quite aware that some people practise syringing Vines morning and evening, but what market growers worthy of the name do so? What value do they get for the Grapes? Do they syringe Lady Downe's in the morning at stoning time? If so, it must be done very early, with heat in the pipes, and ventilation. The latter part of Mr. Bardney's article requires no comment from me, if he keeps to his text.—A. YOUNG.

I PRESUME by Mr. Riding's remarks on page 261, on the subject of Grapes scalding, that he considers it almost impossible to grow Lady Downe's Grape without the berries being more or less scalded. If so I think that must be fancy on his part. But I must beg to remind Mr. Riding that Lady Downe's and Black Hamburghs growing in the same house could not be fairly compared, as the two varieties would not be at the same stage of growth at the same time; the period at which the former would be liable to scald would be passed by the latter. If the two varieties could be grown exactly under the conditions

necessary to ward off the evil, I fail to see any difference in their liability to scald.

With regard to Black Hamburghs grown with little fire heat, I consider they are just as liable to scald as Lady Downe's, if the necessary precautions are not taken. Black Hamburghs not requiring so much heat, are generally more freely ventilated, hence the secret of their more generally escaping the evil. The case Mr. Riding advances, where the Grapes are grown with scarcely any fuel, does not, in my opinion, prove conclusively that there is not a comparison between the two varieties. The "necessary precautions" may have been taken in the one case but not in the other at the proper time. The range he refers to being treated exactly alike accounts for the evil, for I should not think of treating late Grapes exactly the same as early varieties.

Mr. Riding considers "that it would require gross carelessness to accomplish the feat" of scalding Black Hamburghs, but I consider Mr. Bardney's question to Mr. Young is applicable to Mr. Riding. If it is bad management or gross carelessness in the one case, what is it in the other? Perhaps Mr. Young and Mr. Riding would give us their opinion as to why they consider that Lady Downe's Grape is constitutionally or otherwise more liable to scald than any other Grape. I take great interest in Grape-growing, and would gladly welcome any addition to my store of knowledge, and doubtless it would be accepted by many more of our readers, as it is by friendly discussion that knowledge is diffused.

Mr. Riding appears to have been troubled with the scalding of Lady Downe's for the past nine years more or less; but if next season he will pay more strict attention to the fixed temperatures, that I here give for the scalding period (65° at night, air being admitted at the top of the house before the temperature reaches 75° by sun heat, and plenty of air to prevent it rising above 85° until the air of the house is thoroughly dry), and faithfully report the result in the Journal next season, I shall be greatly deceived if he is not satisfied with the result. A few degrees either way of course matters little, and if it is an old fad it may be none the worse for being old.—W. SIMPSON, *Knowsley*.

I SHOULD like to express my opinion with respect to Grapes scalding. Never have I seen Black Hamburghs scald, and if, as Mr. Bardney says, he has had the misfortune to have some so affected, I am of the same opinion as your other correspondents—namely, that there is a mistake in the management. It is evident that the air-giving was not attended to early enough in the morning, or the scalding would never have happened, and particularly with Black Hamburghs.

I will admit that Lady Downe's, under the best of management, will scald sometimes, and especially in such a season as the one we have experienced. Nevertheless, I am in a position to say that we have escaped without any serious loss, and I attribute our success entirely to the ventilation—viz., about 2 inches at the top of the house, and the same at the bottom, with a little fire heat, and as the temperature rises we admit more air. As a proof of the above, we have at the present time as good a house of Lady Downe's as anyone would wish to see, both in colour and size of berries. I quite agree with Mr. Young with respect to fixed temperatures; not on any account would I adopt such a practice, it is against Nature altogether.—R. KIRBY, *Angley Park Gardens*.

THE FRUIT TRADE OF CALIFORNIA.—The British consul at San Francisco, in the course of a report on the agriculture of California, refers to the enormous fruit trade of that State. It produces every kind of fruit that grows in a semi-tropical or temperate climate—among the former are the Orange, Lemon, Citron, Shaddock, and other citrus fruits, the Olive, Pomegranate, Fig, Banana, Apricot, Nectarine, Walnuts, and Almonds, Grapes, producing wine and raisins; belonging to the temperate zone are Apples, Pears, Plums, Cherries, Peaches, Currants, Gooseberries, Blackberries, Raspberries, and Strawberries. The green fruit trade of the State has increased enormously; in 1887 the trade in green fruit with the Eastern States amounted to about 35,000,000 lb. weight. The output of the various canneries in 1886 amounted to about 30,000,000 lb., including 659,950 cases of fruit, 203,500 of vegetables, and 22,500 of jellies and jams. The estimate for 1887 is 792,500 cases of fruit, with an average of about 45 lb. of fruit to the case. Of these, 220,000 cases were Peaches, 175,500 Apricots, 150,000 Pears, 60,000 Cherries, 40,000 Plums, 35,000 Grapes, 25,000 Blackberries, and 15,000 each Strawberries and Gooseberries. The export of dried and evaporated fruits and vegetables is also enormous. Thus the export of Grapes treated in this way in 1887 was 16,000,000 lb., Apricots 3,000,000 lb., honey 1,340,000 lb., French Prunes 1,750,000 lb., Walnuts 1,500,000 lb., Peaches 1,750,000 lb., Grapes 600,000 lb., Apples (evaporated) 550,000 lb., Peaches (evaporated) 1,250,000 lb., Almonds 500,000 lb., Plums 500,000 lb., and smaller quantities of many other fruits. The growing of Grapes for raisins has proved a most profitable crop, with a ready market for all that can be made. Californians believe that their raisin crop will eventually drive the foreign product from the markets of the United States, and from the statistics of the trade the consul is inclined to believe that they will. The wine production in 1887 was 13,000,000 gallons; 150,000 acres of the State are planted with Vines, and not less than 90 per cent. of these are foreign varieties. "That the improvement in the quality of wine produced is very marked there can be no doubt, and the former California wine, with its disagreeable, harsh, foxy taste, is fast becoming a thing of the past. This in due to the importation of the best varieties of foreign Vines, and a more care-

ful system of cultivation, manufacture, and preservation of the wine."—
(*Liverpool Daily Mercury*.)

THE NATIONAL CHRYSANTHEMUM SOCIETY'S CATALOGUE.

THE revised edition of this catalogue for 1888 is just to hand, and without doubt it is the most complete and satisfactory work of the kind yet issued. It comprises sixty-five pages of closely printed matter arranged in the following manner. After the preface, which describes the method adopted in the revision, is a list of the Committee, and a short history of the Chrysanthemum. Then follow the varieties in their several sections, each group being preceded by a brief paragraph giving their characteristics, no formal definition being attempted. In the incurved section eighty varieties are described in alphabetical order, a list of thirty-six being selected from these and "named in the order of merit as determined by the vote" received by each. The Japanese are dealt with in a similar way, eighty-two varieties being described, and forty-eight select varieties are enumerated separately. Section 3 contains the Japanese reflexed, twenty-four varieties described, and twelve selected from these. Of reflexed eighteen are described and twelve selected. Of large Anemones twenty are described and twelve selected. There are fourteen Japanese Anemones and a select list of twelve in the order of merit, fifty Pompons and twenty-four selected, with twenty-four Pompon Anemones and fifteen selected, lists of twenty-four early flowering and eighteen late-flowering varieties also being added. An alphabetical list of varieties of all sections occupies a good portion of the work, brief descriptions being given of those not included in the select lists, with indications in all cases as to the section to which they belong. The catalogue is a neat book, well printed, and a useful addition to Chrysanthemum literature.

In the preface is given the following description of the method adopted:—

When the returns were received they were individually compared with the existing list, and the votes recorded for each variety, necessitating the examination of over 900 printed pages, or about 27,000 names, which portion of the work, including the whole of the select lists, was undertaken by Messrs. Castle and Gordon. In some instances the MS. returns were also considerable; for instance, one member sent over thirty pages of descriptions, corrections, and additions, and altogether not less than 150 pages of MSS. had to be examined, collated, condensed, or elaborated. There was necessarily much repetition, and some unavoidable discrepancies, doubtful points to be elucidated, and questions to be decided that occasioned much more labour than could be imagined from the results set forth in this catalogue. The system of election adopted, however, has enabled the revisers to restrict the lists to the varieties most generally in favour with exhibitors in all parts of the country. The information supplied has also permitted the extension of the descriptions in most cases, the chief characters (following name, raiser, date of introduction or raising, and synonyms) being taken in this order—colour, size and style of bloom, season of flowering, and average height of plant.

Those marked "early" are most unreliable for shows after the first week in November unless the terminal buds are taken, this of course depending to some extent upon the character of the season and the locality where they are grown; but it may be considered as a general indication that the crown bud is too early for exhibition blooms. The varieties recorded, on the other hand, as "late" are generally recommended to be taken on the crown bud for all souther or midland shows, while the midseason varieties can be taken on either bud, according to the condition of the plant and date of the show. But it must be remembered that no absolute rule can be drawn up in these matters, though an attempt has been made, in response to many requests, to give a few hints on a difficult subject. The height indicated "dwarf" in the descriptions is an average of 4 feet; by "medium," 5 feet to 6 feet; and by "tall," 6 feet to 7 feet and upwards.

The Japanese reflexed group has been a source of some difficulty, as a divergence of opinion evidently existed amongst the Committee as to what varieties should be included, and several advocated the exclusion of Cullingfordi from the true reflexed, placing it in the new section. In the determination of this point, as in all others of a similar character, one method only was adopted—namely, taking the majority of the votes, and by this means the Japanese reflexed were selected. It must, however, be observed that some of the varieties received a number of votes both for the Japanese and the Japanese reflexed classes, and adding these together brings the total high in the list. The leading varieties of the select list in this way, and in the order of the number of votes, are the following—Val d'Andorre, Criterion and Elaine, equal; L'Adorable and Jeanne Delaux, equal; M. John Laing, Triomphe du Nord, La Nympe, Dr. Macary, M. Henry Jacotot, Margot and Phœbus. This order, it will be seen, differs from that determined by the number of votes as Japanese reflexed, alone indicated in the list following the

described selections. One variety has been excluded from the select Japanese reflexed first published—namely, Gorgeous, and this has been done because it appears two varieties are in cultivation under the name and there was danger of confusion arising.

CHRYSANTHEMUMS AT FAREHAM.

SPENDING a few days on the south coast, and hearing so much of the southern growers of Chrysanthemums, I decided early one morning to visit one of them. Time being rather short I started for Fareham to look round Messrs. W. & G. Drover's nurseries, not being able to reach Swanmore Park till another time, so I had no trouble in finding Mr. W. Drover, who kindly showed me round. The first three houses were filled with Begonias, Fuchsias, Ferns, &c., of different sizes. The next house, one large span, 40 by 20 feet, was filled with Camellia alba plena, 5 to 7 feet high, having been replanted last March to check their growth; it has well repaid for doing, every plant being well set for bloom. The next house, the same size, is filled with Richardias, of which about 1000 plants are just placed. The other houses are devoted to Gardenias, Stephanotis, plenty of flower being picked at the present time. Two long ranges of glass, 100 feet long, are filled with the most suitable Roses for cutting purposes, as the cut flower trade here is extensive. I must conclude with a few words about the popular flower, the Chrysanthemum, grown here so well and with such numbers of other plants. Messrs. W. & G. Drover must be very energetic, for they look after the Chrysanthemum after the busy day's work is over, the watering of course being done in the day when needed. There are 800 plants grown on the system Mr. Molyneux describes. All the plants as they stood in rows looked very promising. Avalanche looks particularly strong, and plants of W. G. Drover, the pink variety sent out from here, are looking well. All the other varieties are up to the same standard. Several new varieties are growing here to be shown this year for the first time, which I hope to see later on.—A. W. R.

NEW CHRYSANTHEMUMS.

AT a recent meeting of the National Society's Floral Committee the following members were present:—E. Sanderson, Esq., in the chair, and Messrs. W. Holmes, H. Cannell, L. Castle, J. Mardlin, W. Boyce, J. P. Kendall, T. Bevan, R. Owen, G. Steven, and G. Addison. The Chrysanthemums submitted were not numerous, and only three certificates were awarded as follows:—

Chrysanthemum Mrs. Hawkins (Hawkins & Bennett).—This was certificated on the previous day by the Royal Horticultural Society. It is a golden variety of the G. Wermig style, forming with this and Mrs. Burrell a tree of yellow forms of the Madame Desgrange's type, all good early flowering varieties.

Chrysanthemum Fanchette (R. Owen).—A charming Pompon, like Lyon in shape of flower, but of a pleasing light rosy tint, the lower surface of the florets silvery.

Chrysanthemum Mrs. J. Pitcher (J. Pitcher).—A useful early flowering variety, with flowers of a delicate blush hue.

At the same meeting certificates were awarded for the following plants:—Aster Comet and Triomphe (H. Glasscock), Dahlia Mikado (T. W. Girdlestone), Beauty of Brentwood (J. T. West), Gertrude (H. Glasscock), Miss Ramsbottom (T. S. Ware), Victoria (J. Cheal and Sons), Admiration and Kathleen (C. Turner); Pompon Dahlias Fairy Tales, Little Ethel, Little Darkie, and decorative Panthea, from Messrs. Keynes Williams & Co., Carnation Mrs. Reynolds Hole (Dicksons & Co.), Pelargonium Robert Owen (R. Owen), with Gladiolus Mrs. Lindrell and Phyllis from Messrs. Burrell.

SMALL FRUIT FARMS.

THE first farmer was a gardener and a fruit grower. His labour consisted in caring for the trees that yielded the fruits on which he subsisted. In tropical countries where fruits ripen through the year men still largely live on the products of the Banana, which it has been said produces a greater amount of nutriment per acre than any kind of grain. It is quite possible that some kinds of small fruits, and especially the Grape, might contest with the Banana for supplying man's wants for food from small areas. The small fruits are veritable foods and not mere relishes, as they are too often considered. If used as food more extensively mankind would be healthier and happier. Then fruit-growing, as it conduces to this result, is a benefit to the race. By diversifying farm labour it also helps to make all branches of farming more profitable.

In some sections of country where fruit generally succeeds the devotion of entire farms to the growing of fruit has become quite common, and is liable to be still more so. It is every year more evident that for exclusive grain-growing of any kind the Eastern farmer cannot compete with the great West. In fact, the Western farmer is himself hard pushed to compete successfully in Wheat production with the Wheat of Russia and India. It is this which within a few years has so largely stimulated the making of butter and cheese at the West. There is money in dairy products for Western farmers on cheap lands, especially as these enable them better than grain-growing to maintain the fertility of their soil. But with the West monopolising grain and dairy products what is there for the Eastern farmer?

Fruit-growing seems the most natural answer to this inquiry. There are many advantages in this kind of farming. It does away with the need of expensive machinery required in grain-growing or the more

expensive outfit in cows needed by the dairymen. By dividing attention between a variety of fruits the farmer can provide something to do most of the time and some revenue through a large part of the year. This kind of business necessitates the subdivision of farms. It is impossible for a man to properly care for more than a few acres of the small fruits, and a part of his land should be in Apples, Pears, and Quinces, which require less continuous care during the growing season than do the various kinds of berries.

The change to this kind of farming should be made gradually. Only the small fruits will pay anything for the first two or three years. Strawberries give their best crop a year after planting. Raspberries and Blackberries are a year later, but will bear several crops without needing to be renewed.

We do not believe there is serious danger of overdoing the production of any kind of good fruit. If the market is glutted and prices are low it is usually more the fault of inferior quality, a deficient distribution than of excessive supply. To some extent the choicest fruit makes its own market; but it needs some business enterprise and push to bring producer and consumer together. Farmers sometimes complain that the middleman takes too large a share of the profits. If he does so in the sale of fruit let them try doing their own marketing. In almost every rural neighbourhood are families doing without fruits who would gladly buy them if brought to their doors as they are in the city. It is rather odd that while fruits and vegetables are altogether grown in the country people have been obliged to go to the city markets to obtain them.

This arises mainly from the fact that fruit-growing is made incidental to other farming, or is so extensive that only wholesale methods of disposing of fruit are practicable. But the middleman is obliged to take an extreme profit out of fruits because of their perishable character. It is for this reason that fruit growers should, so far as possible, market the products of their land themselves. This necessarily limits the area they can cultivate and care for, including harvesting and marketing, though extra help will always be needed when the fruit is ready to be gathered to have the crop saved without waste.

Can a farmer make a fair living and provide competency against old age from fruit-growing on small areas? Thousands are doing this and there is room for many more. It is not a business that dazzles with ambitious hopes of enormous profits. No branch of farming offers such tempting prizes of great wealth as do the mercantile and professional careers. But there are also fewer blanks. Most of the failures in farming come from trying to do too much. This is more true of fruit-growing than of anything else, for the reason that most of the work requires greater care than can be given on an extensive scale.—(*American Cultivator*.)

HELIANTHUS MULTIFLORUS PLENUS.

THIS is one of the few plants that seem to defy the elements, for although it has rained daily for the past fortnight it is covered with its bright yellow flower heads. It thrives amazingly in the neighbourhood of towns; in fact, it seems at home in any position where the soil is fertile. For the past three weeks it has been particularly conspicuous amongst clumps of dark foliaged Hollies, and will continue until severe frosts set in. Light frosts that will destroy Dahlias do not appear to injure it in the least. If these plants are allowed to grow undisturbed for a few years, clumps of large size are formed, carrying hundreds of flowers serviceable for cutting. We have found it one of the most useful plants in the garden for supplying flowers for church decorations; it appears specially adapted for harvest festivals. All who have to supply flowers in quantity for decorations of this description, and do not object to the colour, will find this double *Helianthus* one of the most profitable plants that can be grown.

It is easily propagated by division. The best plan perhaps is to lift one good plant early in the year, and scores of small fleshy tubers will be found. If these are placed in boxes, or singly in pots, and placed under glass, they will make strong plants with a single stem by the end of May, when they may be planted outside. They will produce a few flowers the first season, but the second they will be strong plants, and flower profusely.—G.

THE PROGRESS OF BOTANY.

At the recent meeting of the British Association in Bath, Mr. W. T. Thiselton Dyer, Director of the Royal Gardens Kew, presided in the section devoted to Biology, and delivered an address on botanical subjects, from which the following extracts (from a full report in *Nature*) may be found of interest to our readers.

It is not so very long ago that at English Universities, at least, the pursuit of botany was regarded rather as an elegant accomplishment than as a serious occupation. This is the more remarkable because at every critical point in the history of botanical science the names of our countrymen will be found to occupy an honourable place in the field of progress and discovery. In the seventeenth century Hooke and Grew laid the foundation of the cell-theory, while Millington, by discovering the function of stamens, completed the theory of the flower. In the following century Morrison first raised Ferns from spores, Lindsay detected the Fern prothallus, Ray laid the foundation of a natural classification, Halcs discovered root-pressure, and Priestley the absorp-

tion of carbon dioxide and the evolution of oxygen by plants. In the early part of the present one we have Knight's discovery of the true cause of geotropism, Daubeny's of the effect upon the processes of plant life of rays of light of different refrangibility, and, finally, the first description of the cell-nucleus by R. Brown. I need not attempt to carry the list through the last half-century. I have singled out these discoveries as striking landmarks, the starting points of important developments of the subject. It is enough for my purpose to show that we have always had an important school of botany in England, which has contributed at least its share to the general development of the science.

I think at the moment, however, we have little cause for anxiety. The academic chairs throughout the three kingdoms are filled, for the most part, with young enthusiastic, and well-trained men. Botany is everywhere conceded its due position as the twin branch with zoology of biological science. We owe to the enlightened administration of the Oxford University Press the possession of a journal which allows of the prompt and adequate publication of the results of laboratory research. The excellent work which is being done in every part of the botanical field has received the warm sympathy of our colleagues abroad. I need only recall to your recollection, as a striking evidence of this, the remarkable gathering of foreign botanists which will ever make the meeting of this Association at Manchester a memorable event to all of us. The reflection rises sadly to the mind that it can never be repeated. Not many months, as you know, had passed before the two most prominent figures in that happy assemblage had been removed from us by the inexorable hand of death. In Asa Gray we miss a figure which we could never admit belonged wholly to the other side of the Atlantic. In technical botany we recognised him as altogether in harmony with the methods of work and standard of excellence of our own most distinguished taxonomists. But, apart from this, he had that power of grasping large and far-reaching ideas, which, I do not doubt, would have brought him distinction in any branch of science. We owe to him the classical discussion of the facts of plant distribution in the northern hemisphere which is one of the corner-stones of modern geographical botany. He was one of the earliest of distinguished naturalists who gave his adhesion to the theory of Mr. Darwin. A man of simple and sincere piety, the doctrine of descent never presented any difficulty to him. He will remain in our memories as a figure endowed with a sweetness and elevation of character which may be compared even with that of Mr. Darwin himself.

In De Bary we seem to have suffered no less a personal loss than in the case of Gray. Though, before last year, I do not know that he had ever been in England, so many of our botanists had worked under him that his influence was widely felt amongst us. And it may be said that this was almost equally so in every part of the civilised world. His position as a teacher was in this respect probably unique, and the traditions of his method of work must permanently affect the progress of botany, and, indeed, have an even wider effect. This is not the occasion to dwell on each of his scientific achievements. It is sufficient to say that we owe to him the foundation of a rational vegetable pathology. He first grasped the true conditions of parasitism in plants, and not content with working out the complex phases of the life-history of the invading organism, he never lost sight of the conditions which permitted or inhibited its invasion. He treated the problem, whether on the side of the host or of the parasite, as a whole—as a biological problem, in fact, in the widest sense. It is this thorough grasp of the conditions of the problem that gives such a peculiar value to his last published book, the "Lecture on Bacteria," an admirable translation of which we owe to Prof. Balfour. To this I shall have again to refer. I must content myself with saying now, that in this and all his work there is that note of highest excellence which consists in lifting detail to the level of the widest generality. To a weak man this is a pitfall, in which a firm grasp of fact is lost in rash speculation. But when, as in De Bary's case, a true scientific insight is inspired by something akin to genius, the most fruitful conceptions are the result. Yet De Bary never sacrificed exactness to brilliancy, and to the inflexible love of truth which pervaded both his work and his personal intercourse we may trace the secret of the extraordinary influence which he exerted over his pupils.

SYSTEMATIC BOTANY.

As the head of one of the great national establishments of the country devoted to the cultivation of systematic botany, I need hardly apologise for devoting a few words to the present position of that branch of the science. Of its fundamental importance I have myself no manner of doubt. But as my judgment may seem in such a matter not wholly free

from bias, I may fortify myself with an opinion which can hardly be minimised in that way. The distinguished chemist, Prof. Lothar Meyer, perhaps the most brilliant worker in the field of theoretical chemistry, finds himself, like the systematic botanist, obliged to defend the position of descriptive science. And he draws his strongest argument from biology. "The physiology of plants and animals," he tells us, "requires systematic botany and zoology, together with the anatomy of the two kingdoms; each speculative science requires a rich and well-ordered material, if it is not to lose itself in empty and fruitless fantasies." No one, of course, supposes that the accumulation of plant specimens in herbaria is the mere outcome of a passion for accumulating. But to do good systematic work requires high qualities of exactitude, patience, and judgment. As I had occasion to show at the Linnean Centenary, the world is hardly sensible of the influence which the study of the subject has had on its affairs. The school of Jeremy Bentham has left an indelible mark on the social and legislative progress of our own time. Mill tells us that "the proper arrangement of a code of laws depends on the same scientific conditions as the classifications in natural history; nor could there," he adds, "be a better preparatory discipline for that important function than the principles of a natural arrangement, not only in the abstract, but in their actual application to the class of phenomena for which they were first elaborated, and which are still the best school for learning their use." He further tells us that of this Jeremy Bentham was perfectly aware, and that his "Fragment on Government" contains clear and just views on the meaning of a natural arrangement which reflect directly the influence of Linnæus and Jussieu. Mill himself possessed a competent knowledge of systematic botany, and therefore was well able to judge of its intellectual value. For my part, I do not doubt that precisely the same qualifications of mind which made Jeremy Bentham a great jurist, enabled his nephew to attain the eminence he reached as a botanist. As a mere matter of mental gymnastic, taxonomic science will hold its own with any pursuit. And, of course, what I say of botany is no less true of other branches of natural history. Mr. Darwin devoted eight or nine years to the systematic study of the Cirripedia. "No one," he himself tells us, "has a right to examine the question of species who has not minutely described many." And Mr. Huxley has pointed out, in the admirable memoir of Mr. Darwin which he has prepared for the Royal Society, that "the acquirement of an intimate and practical knowledge of the process of species-making. . . was "of no less importance to the author of the 'Origin of Species' than was the bearing of the Cirripede work upon the principles of a natural classification."

At present the outlook for systematic botany is somewhat discouraging. France, Germany, and Austria no longer possess anything like a school in the subject, though they still supply able and distinguished workers. That these are, however, few, may be judged from the fact that it is difficult to fill the place of the lamented Eichler in the direction of the Botanic Garden and Herbarium at Berlin. Outside our own country, Switzerland is the most important seat of general systematic study, to which three generations of De Candolles have devoted themselves. The most active centres of work at the moment are, however, to be found in our own country, in the United States, and in Russia. And the reason is, in each case, no doubt the same. The enormous area of the earth's surface over which each country holds sway brings to them a vast amount of material which peremptorily demands discussion.

No country, however, affords such admirable facilities for work in systematic botany as are now to be found in London. The Linnean Society possesses the Herbarium of Linnæus; the Botanical Department of the British Museum is rich in the collections of the older botanists; while at Kew we have a constantly increasing assemblage of material, either the results of travel and expeditions, or the contributions of correspondents in different parts of the Empire. A very large proportion of this has been worked up. But I am painfully impressed with the fact that the total of our available workers bears but a small proportion to the labour ready to their hands.

This is the more a matter of concern, because for the few official posts which are open to botanists at home or abroad a practical knowledge of systematic botany is really indispensable. For suitable candidates for these one naturally looks to the Universities. And so far, I am sorry to say, in great measure one looks in vain. It would be, no doubt, a great impulse to what is undoubtedly an important branch of national scientific work if Fellowships could occasionally be given to men who showed some aptitude for it. But these should not be mere prizes for undergraduate study, but should exact some guarantee that during the tenure of the Fellowship the holder would seriously devote himself to some definite piece of work. At present, undoubtedly, the younger

generation of botanists show a disposition to turn aside to those fields in which more brilliant and more immediate results can be attained. Their neglect of systematic botany brings to some extent its own Nemesis. A first principle of systematic botany is that a name should denote a definite and ascertainable species of plant. But in physiological literature you will find that the importance of this is entirely overlooked. Names are employed which are not to be found in the books, or they are altogether misapplied. I call to mind the case of an English physiologist who wrote a highly ingenious paper on the movement of water in plants. He was content to refer to the plant upon which he experimented as the "Bay Laurel." I ascertained that the plant he really used was the Cherry Laurel. Now the Bay is truly a Laurel, while the Cherry Laurel is a Plum. Anyone repeating his experiments would therefore be led wholly astray. But if proper precautions are taken to ascertain the accurate botanical name of a plant, no botanist throughout the civilised world is at a loss to identify it.

GEOGRAPHICAL BOTANY.

But precision in nomenclature is only the necessary apparatus of the subject. The data of systematic botany, when properly discussed, lend themselves to very important generalisations. Perhaps those which are yielded by the study of geographical distribution are of the most general interest. The mantle of vegetation which covers the surface of the earth, if only we could rightly unravel its texture, would tell us a good deal about geological history. The study of geographical distribution, rightly handled, affords an independent line of attack upon the problem of the past distribution of land and sea. It would probably never afford sufficient data for a complete independent solution of the problem; but it must always be extremely useful as a check upon other methods. Here, however, we are embarrassed by the enormous amount of work which has yet to be accomplished. And unfortunately this is not of a kind which can be indefinitely postponed. The old terrestrial order is fast passing away before our eyes. Everywhere the primitive vegetation is disappearing as more and more of the earth's surface is brought into cultivation, or, at any rate denuded of its forests.

(To be continued.)

ERICA ALPORTI.

THIS Heath is just now the prettiest plant in the garden, for it is a mass of its rich dark crimson flowers. It does not grow so rapidly as some, but it is one of the best for the rock garden where a sunny, open position can be given it. Peat is evidently not necessary for these plants; they grow here luxuriantly in loam. *Erica vagans rubra* grows rapidly, and soon attains a large size. Some plants not a foot over them three years ago are now fully 3 feet in diameter. This variety is flowering better with us than it has done before. Many of its spikes are 9 inches in length, although all the flowers are not yet open. The white-form of this variety does not grow so strongly, but it is a grand companion to it, and to make large bushes only requires two or three plants placed together instead of planting them singly. It is to be deplored that beds of these beautiful *Ericas* are not more generally seen in suitable positions in pleasure grounds. A few plants of each variety together soon form conspicuous clumps if the centre plants are raised by the aid of a few stones. *E. Alporti* would certainly give more trouble in keeping it well furnished at the base than some other varieties, for it is of upright growth and liable to become bare at the base, but, in spite of this, it is perhaps the most charming of all.—B., *Liverpool*.

BRENTWOOD SHOW.

THE autumn Show and Exhibition of farmers' and cottagers' produce was held on Thursday last, September 20th, under most favourable conditions, the weather being all that could be desired. Special prizes for cottagers were given by the tradesmen of Brentwood. Ploughing prizes by Mr. Beadel, M.P. Owing, however, to the lateness of the season this competition was postponed for a fortnight. Long servitude for farm servants by the President, Mr. E. Ind. and Lady Guise offered similar prizes to domestic servants. Added to this a fire brigade competition and a display of fireworks rendered additional attractions. The entries numbered about 700. Messrs. Cheal & Sons of Crawley, Sussex, exhibited, not for competition, a fine collection of Dahlias single, Cactus, and Pompon, the most notable of the singles being Victoria, a dark crimson variety with white band down centre of each petal; Mr. Rose, Alphonso, Formosa, and Mr. Kennett; Pompons—Iolanthe, E. F. Junker, Darkness, and Isabel. The same firm also exhibited a collection of Apples, Pears, and Plums. In the open class for twenty-four Dahlias, distinct, Mr. Keith of Cornwall, Brentwood, was first, closely followed by Messrs. Saltmarsh & Sons, Chelmsford. For twelve Dahlias, amateurs, Mr. Keith and Mr. Harris for first and second. For six Dahlias, Mr. Ocock, gardener to Mrs. McIntosh, Havering Park, was first, and Mr. Tunbridge second. For twelve Dahlias, special prizes offered by Messrs. Rawlings Bros., Romford, Messrs. Keith, Ocock, and Tunbridge were placed in the order named. There was a good display

of Roses considering the lateness of the season. For twenty four Roses, distinct, open, the Rev. J. H. Pemberton was first, Mr. Frank Cant second. For twelve Roses, distinct, amateurs, the Rev. J. H. Pemberton was first, and Mr. Wallis, Cornsland, Brentwood, was second. For six distinct, Mr. Nairn of Romford was first, an equal second being awarded to Messrs. Charter and Atkinson of Brentwood. Fruit was exhibited in good condition by Mr. Ocock, Mr. F. Brown, and Mr. Tunbridge; Mr. Ocock also showing a fine collection of vegetables. A great feature of the Show was the fine display and keen competition in the cottagers' classes, two large tents being well filled. As an example may be mentioned the class for collection of vegetables, six varieties, for which three prizes were offered; here there were eleven competitors, all showing such good baskets that one regretted no one had taken the place of the late Countess Tasker, who was accustomed to award extra prizes when the competition was keen and the exhibits up to the mark. This was not the only class in which the competition was severe; for instance, in that for a collection of four sorts of vegetables there were ten competitors, for kidney Potatoes twenty-two, for twelve Onions twenty, for the best dish of boiled Potatoes twenty-four, and for nosegay of wild flowers by children twenty-nine competitors. These are only some of many other classes filled in like manner. The Society is to be congratulated upon the success of the Show, especially in the cottagers' division, and it is hoped that some ladies and gentlemen of the neighbourhood, following the good example already mentioned, will place it in the power of the Committee to make extra awards should the exhibits deserve it, as they certainly did last Thursday.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Unsatisfactory Trees.*—Where the trees cast their buds, do not set well, swell irregularly, stone badly, and finish their crops unsatisfactorily, then something is wrong. If the disaster is not attributable to errors in the treatment, something is amiss with the roots. Either they are in unsuitable material, it is too rich or loose, too deep or imperfectly drained. Trees not in a satisfactory condition, and it not being attributable to bad treatment, should as soon as the wood is mature be partially or wholly lifted. If this be done whilst the trees are in leaf the house should be shaded before commencing operations, and the old border made thoroughly moist. In removing the old soil commence at the point most distant, and work towards the trees, and when it has been cleared away the exposed roots should be drawn aside, damped, and covered with mats whilst the drainage is being attended to. This should consist of 9 to 12 inches thickness of rubble, largest at the bottom and smallest at the top, and if a covering be placed on of chalk the size of road mettle, or the rough of old mortar rubbish not passing a sieve with a three-quarter inch mesh, it will make all secure and be a source of calcareous matter. If the site be wet it may be necessary to concrete the bottom below the drainage; in any case there must be drains beneath the drainage, the bottom sloping to carry off all water, and it must have proper fall and outlet. Strong loam is most suitable. If inclined to be light add a fourth of clay marl as fine as practicable; if very strong add a fourth of road scrapings, and in any case a tenth of chalk or old mortar rubbish freed of laths or other pieces of wood. Crushed steamed bones may also be added to the extent of a twentieth part, and a similar proportion of wood ashes, the whole well incorporated, and as put in the border rammed firmly, and the roots, after having any strong fibreless portions shortened with a knife, must be spread out evenly over the bed, covering them with soil as they are laid out, and give a good watering. The roots should, as far as practicable, be laid in the top foot of soil. The border need not be deeper than 24 inches, and in no case wider than the width or height of the trellis. The shading must remain on if the weather be bright, and afford ventilation by the top lights only, syringing the foliage morning and afternoon until it is seen that the roots are working in the fresh compost, when the shading may be removed and the house opened. Trees so treated rarely cast their buds, the flowers set well; indeed the operation of lifting is very commendable in many ways, but is little practised. Trees in good health will not require lifting, but it is a good practice, especially for old trees, to remove some of the soil from the surface and supply fresh compost, as the roots will benefit by it, adding to their vigour and the size and quality of the fruit produced.

Late Houses.—When the fruit has been gathered, as will be the case where there are midseason varieties, the next important object is to secure the ripening of the wood. This can best be done by thinning unnecessary shoots in addition to those that have borne fruit, the latter being cut out to a successional shoot at the base, and the former being thinned wherever overcrowded. In the case of strong vigorous trees it may be necessary to accelerate the ripening of the wood by gentle fire heat, especially in dull weather, at the same time admitting air freely. Some of the late Peaches, as *Desse Tardive*, *Walburton*

Admirable, *Sea Eagle*, &c., in cold localities will require gentle fire heat to ripen them thoroughly. An occasional syringing will be necessary for trees from which the fruit has been gathered.

CUCUMBERS.—Liberal treatment is essential to obtain and maintain a strong growth in the plants for autumn fruiting, as much of the after success depends on the foundation now laid. Remove all staminate flowers and tendrils, avoiding overcropping, and be careful not to allow the fruits to hang too long upon the plants. Gradually reduce the atmospheric moisture as the days shorten, and employ the syringe only on bright warm afternoons. Earth up the roots from time to time, pinching out the growing points of the shoots about every week or ten days, reserving as much foliage only as will admit of its exposure to light and growth to ensure a succession of fruit. The water supplied should be about the same temperature as the bed.

The plants for winter fruiting must be in their places about the middle of October to ensure a good supply at Christmas. Keep them near the glass to ensure sturdy growth, not allowing them to become root-bound. See that the fermenting material is in due course of preparation if any is to be employed for bottom heat, and make certain of the heating apparatus being in thorough order. A bottom heat of 85° to 90° will be safe, but the latter temperature should not be exceeded; if from hot-water pipes a bottom heat of 80° to 85° is sufficient. As there are many failures with winter Cucumbers from disease it will be advisable to take extra precautions in the way of thorough cleanliness and choice of soil. Turfy loam of a rather light nature is best, cut about 3 inches thick with the turf, and this baked in an oven or over a fire, being careful not to bake it to a cinder, but only sufficiently to destroy fungoid and nematoid germs, a temperature of 212° being ample, but this will not prevent attacks of the plants by nematoids, which result of continuance by seed or otherwise of a diseased parent, as it is inherent in the progeny. About a third of old mortar rubbish may be added, especially if there is a tendency in the loam to produce gumming in the plants and fruit, and this more particularly applies when the loam is of a very fibrous or peaty nature. If the loam be rather heavy add grit or road drift, and put it together rather firmly so as to induce a sturdy growth. Manure is best given at the surface as a mulch or in liquid form.

MELONS.—Cankered and cracked fruit are most frequent during cold and wet weather. The best practice is to keep both the soil and atmosphere dry, and for canker fresh slaked lime well rubbed into the affected parts. Cease syringing the foliage, and supply water at the roots to prevent flagging, but no more. Remove all superfluous growths. The late fruits are swelling and must be supported. Maintain a night temperature of 65°, and 70° to 75° by day artificially, closing the house early in the afternoon, keeping through the day at 80° to 90° from sun heat.

After this time cease applying water to plants in dung-heated pits and frames, a dry condition at the roots will accelerate the ripening process. Any fruits that have finished swelling, or plants that are dying, should be cut with a good portion of stem and placed in a dry warm house to ripen.

THE FLOWER GARDEN.

Flower Beds.—These have been more attractive during September than at any time previous, both the fine-foliaged and flowering plants improving surprisingly under the influence of dry weather and warmth. The tuberous Begonias have fairly eclipsed everything, and they promise to be very gay till frosts cut them down. In some instances, or where there are a few isolated beds of Begonias, Aster, Zinnias, Stocks, and other plants that are later than usual in flowering, it is advisable to protect them in some way so as to prolong their beauty and usefulness. Carpet beds, when not forming part of a general arrangement—that is to say, when not mixed with various other beds, ought also to be protected as much as possible from heavy rains and during cold frosty nights. Close canvas stretched over the beds and securely fastened to stout short stakes forms the best covering, but frigi domo or cotton blinds, such as are used for covering outside wall trees, mats, or some other substitute, would also be better than no protection at all. In every case the coverings ought to be securely fastened well above the plants, or otherwise a storm of wind and rain will cause them to do much more harm than good to the flowers underneath.

Late Propagation.—Owing to the rather late flowering of the Zonal Pelargoniums especially, many owners were averse to the requisite number of cuttings being taken from them, thus disfiguring the beds somewhat. As a consequence late propagation must be resorted to, or otherwise there will be a scarcity of strong plants next spring. Carefully treated, and cuttings not actually damaged by frosts, may be struck and safely wintered, these proving superior to the bulk of those struck in the spring. All should have most of the old leaves and scales trimmed off them, and after being well dried, be dibbled round the sides of 4-inch or rather smaller pots. These to be set on shelves suspended in dry Peach houses, vineries, or in any dry light position, where a little fire heat is turned on in wet cold weather. No water should be given for several days, and at no time during the winter ought they to have more than enough to prevent shrivelling. Keep all Pelargonium cuttings free of decaying leaves and on the dry side, it being undesirable to encourage growth at this time of year. Uninjured tops of young shoots of *Heliotropes*, *Verbenas*, *Ageratums*, *Petunias*, *Marguerites*, *Iresines*, *Coleuses*, and *Alternantheras* may yet be struck in gentle heat. They ought to be kept rather close, sufficient air being given every morning to well dry the frames in which they are set, or otherwise wholesale damping off will result. Young plants are, in most instances,

preferable to old plants potted up from the ground, but the latter ought at once to be secured if the former are scarce. Carefully lifted, not too much of the heavy garden soil with them, and kept in a rather shady yet warm position, many of these old plants will survive and give a quantity of cuttings early next spring.

Calceolarias, Violas, and Gazanias.—Plenty of good cuttings of these can usually be had early in October, and that is the best time to propagate. Struck much earlier they are apt to grow too strongly and be less hardy in consequence, while if not taken off before frosts injure them many of the cuttings will fail to strike. No heat whatever is needed for them, in fact they do much better without it. Cold frames and shallow pits are the best form of covering for them. The former should be set on a dry bottom, and in either these or pits place sufficient half-rotten heating material, such as leaves and stable manure, to bring the soil placed on the top of this well up to the glass. About 4 inches of light loamy soil should be levelled over the manure, on the top of this being placed 2 inches of compost consisting of equal parts of fine loam and sifted leaf soil with a liberal addition of sharp sand, patting this down firmly with the back of the spade. In the case of shrubby *Calceolarias* the best cuttings are made from the medium-sized flowerless shoots now very abundant. These should be shortened to a length of about 3 inches, cut to a joint and dibbled in 3 inches apart each way before they flag badly. Flowering tops of *Violas* may be struck, and will eventually form good plants, but the preference ought to be given to the young shoots that start from the stem of the old plants. These need very little preparation, and may be dibbled in more thickly than the *Calceolarias*. Short tops of *Gazanias* to be made into cuttings and treated similarly to *Calceolarias*. The cuttings in every instance must touch the bottom of the holes made with the dibber, and be further fixed with the point of the latter. All to be watered in, be kept rather closely covered in the daytime, and be shaded from bright sunshine. In mild dull weather a pinch of air may be given, especially during the night time, the aim being to keep the cuttings from damping off and to check premature top growth.

Planting Bulbs.—Those intended for the flower beds cannot yet be planted, but in all cases where the bulbs can be planted at once this should be done. Especially is it necessary to plant the home-grown bulbs of *Lilium candidum*, *Narcissi* in variety, and notably the Pheasant Eye, and the double form of it, as these when received have usually commenced root action. It is always the wisest plan to put out hardy flowering bulbs generally in clumps where they can be properly taken care of, and not disturbed for several years. They are very fit plants for mixed borders, and if properly arranged will give a very serviceable display of flowers without greatly interfering with the space required for summer flowering plants. Irises in variety, *Fritillarias*, *Leucojums*, *Triteleias*, *Anemones* in great variety, *Hyacinths*, *Narcissi* and *Daffodils*, *Tulips*, *Crocuses*, *Scillas*, *Snowdrops*, and the hardy *Lachenalias* improve rather than deteriorate from being left in the ground, and ought to be ordered and planted at once. In the course of three or four seasons strong clumps will have formed where only three or four bulbs were planted, and these may be lifted, divided, and replanted at any time during the autumn or early spring months. The beautiful *Ranunculus* are not so hardy as those just named, and these must be kept out of the ground till November, and even later in cold damp localities.

PLANT HOUSES.

Eucharis grandiflora.—If any of the plants need potting or it is necessary to increase the stock by division, this is a very good time to do it. After shaking the soil from their roots, keep them close and shaded for ten days, and they will commence to root afresh in the new soil. The pots should be liberally drained, as these plants dislike stagnant water or sour soil about their roots. They enjoy liberal supplies of water, but the soil must be sweet and open. The plants will pass the winter much better with sweet fresh soil in which to root than if it was approaching a sour exhausted condition. *Eucharises* frequently flower at this season of the year, and those that have not flowered should be kept until they have done so. It is a mistake where a long succession of bloom is required to disturb the whole of the stock at the same time. They should be divided into batches, so that repotting can be done without throwing quantities of them into flower at a time when they may not be wanted. Water carefully after potting, never allow the plants to become dry, and on the other hand do not overwater them. *Eucharises* are frequently given too much water, especially during the winter, and the result is that in spring they are almost rootless.

Stephanotis floribunda.—Plants that are intended to flower early should have no artificial heat for at least a month. On fine bright days admit abundance of air. Discontinue syringing, as the atmosphere of the structure must be drier than has been the case up to the present time. This will bring growth to a standstill and harden and ripen the wood. The plants will then be in grand condition for pruning and to enjoy a season of complete rest. After pruning, and during the resting period, every attempt should be made to destroy mealy bug if the plant is infested. The plant should be pruned as it is taken from the trellis, and then washed in a strong solution of soft soap and water in a tank. Nail brushes may be used to remove any small bug that may have deposited itself in the axils of the leaves. Wash the house, and if there is much bug about, the wires and every available space should be painted with petroleum. The plant should then be thoroughly syringed while it is down with one ounce of the oil in each gallon of the water, being careful to get at every portion of it. After the plant has laid for an hour or so shake it well, as the oil might settle upon the

lower portion and destroy some of the branches. The plant should then be trained thinly over the roof, and syringed again with the same solution, repeated at intervals of a month until the flowering time. A large plant subjected to this treatment has given us no trouble this year to keep it thoroughly clean.

Poinsettias.—These must be removed from cold frames without delay and placed in a light structure where a night temperature of 55° to 60° can be maintained. The latter will not hurt them provided liberal ventilation is given during fine days. Directly the plants commence showing their bracts or the completion of their growth, the temperature may be raised 5°. Clean the houses thoroughly before these and other winter flowering plants are placed in them. *Plumbagos*, *Linums*, *Centropogons*, and *Euphorbias* must also be removed from cold frames. Be careful not to keep any of these too warm to excite them into fresh growth.

Crotons.—Those for decoration that are highly coloured must be prevented making fresh growth. This can be accomplished by placing them in cooler quarters and admitting more air during the day. *Crotons* will bear without injury a night temperature of 55°, and if they are not kept too warm during the day they will remain in excellent condition until they are wanted. The decorative value of *Crotons* is often destroyed by growth made in autumn, which it is impossible to colour.

THE BEE-KEEPER.

NOTES ON BEES.

It may be worth remarking that while in many places the rain only drizzled, here during the months of July, August, and part of September it fell in torrents, the drops being of immense size. Late as the season is a continuance of fine weather may favour the bees, and a few more pounds of honey may still be gathered. Good hives, it is said, have risen in weight 30 lbs., but I have not seen them since the middle of August. On the 10th of September a number of Carniolian queens came by post from Austria, which have superseded the same number of unfertilised ones in nuclei. An examination of these proved that only one had commenced to lay at about ten weeks old, while older ones had not. This one, unfertilised as she was, had previously been subjected to rough treatment by the bees. Twice I released her from being killed when outside, a common occurrence when fertilisation is delayed. The brood of this queen presented a peculiar appearance, being very rugged, more so than is usually the case, and some of the cells appeared extra large, two bees in one cell. On opening one of them two well advanced pupæ were in one cell. Amongst the varied phenomena of the hive it is the first of the kind I have either heard of or seen, nor have I ever witnessed either malformed or monstrosities amongst bees other than hermaphrodites. These latter are sometimes interesting, especially so to the scientist. Why bees are exempt from producing mature malformed bees like many other animals may, perhaps, be due to their perfect knowledge of the ulterior uselessness, or otherwise, of any malformed larva found in the unsealed cell, but why do they allow hermaphrodites to become fully developed is matter for reflection. At a later date I will examine this brood, as it appears the bees, although supplied with a fertile queen, have retained all the drone brood, much of it being now near the hatching.

Usually when bees have a fertile queen introduced, superseding a drone-breeding one, the bees destroy the drone brood. It appears, however, that in this as in other things the Carniolian bee differs from other varieties. When bees of the common kind lose their queen they shortly thereafter make a great commotion, usually near dusk, which gives the bee-keeper notice that the hive is queenless. The Carniolians appear to act differently in this respect, indicating queenlessness by fanning at the entrance, and humming loudly, just as bees do when they have been fed or getting honey in abundance. This difference makes it more difficult to distinguish queenless hives by appearance. Another trait in their character is they take more readily to a strange queen than some varieties do, so much so indeed that I believe that in many cases an alien queen might be introduced safely in ten minutes after the deposition of

the original one. I have introduced many queens to these bees and found every lot of the same nature.

When these bees are pure they are grand workers and have otherwise all the good qualities desirable in bees, and if we overlook their friskiness at swarming time are otherwise faultless. And when their mild temper (although not stingless) is taken into consideration they are unsurpassed, and no other variety can be compared with them.

A DAY'S OUTING.

One day lately a letter came from a friend asking me to visit him and others, and advise the best plan to prepare different hives for winter. Their plan was to drive and join two together. After making an examination I found every hive well filled, and there was no necessity whatever for further strengthening any one of them. The honey that could be taken was but little, for already an octagon super tolerably well filled had been taken from each hive, for which I was informed 2s. 6d. per pound would be readily obtained. Their mode of marketing being after the fashion I have frequently spoken on—viz., they hand it over to a grocer, and he sells it at the price named by the owner, a small per-centage being allowed for the trouble. After I had satisfied myself as to the actual condition of all the hives, and seeing no necessity for more bees, nor that any good could arise from joining two together, I explained the whole matter, and advised feeding those hives requiring it, and probably when the spring came round there would be a demand for bees, as many had died during this summer. An outlay of from 3s. to 4s. was all that was necessary to make them worth six or seven times more by May next. Now came the important reply to what I said from a bee-keeper of the first year. "I agree with what you say, but the number of hives I can keep is limited, then if there was no demand in the spring there would likely be as little demand in the autumn. It appears to me that the 'brimstone pit' is the best way to dispose of surplus bees after all that has been said against it." In that statement I concurred, but added that there were ways and methods of getting over the difficulty and avoiding the pit, although no writer on bees had as yet shown the way to rescue the innocents. Successful bee-keeping to many of them consisted in manipulation and increase of stocks, which if performed in a humane and intelligent manner would result in the country being overflowed with bees, but this has never been the case, and the number of slaughtered bees from other causes has been greater of late than the brimstone pit ever caused. Just as the Stewarton system of bee-keeping has given supers of honey this year when others failed, as I have frequently shown it could do, although condemned by most of our modern bee-men, until lately when they could not do so conscientiously any longer, so will I endeavour now to show how bees can be kept with the greatest amount of profit without having many surplus bees, and none to subject to brimstone. Before doing so, however, I may state that in addition to the octagon supers stated above I hear of many others, and in one case in the East of Scotland 50 lbs. surplus has been taken from each Stewarton hive.

HOW TO MAKE THE MOST OF BEES.

Take any given number, say six stocks; the bee-keeper having no desire to increase nor to have "condemned bees." Allowing these six stocks to swarm there would be twelve in all; but the six swarms are combined into three, leaving still three in excess. To still further reduce these drive all the adult bees from one half, then combine these three hives with the other three. This reduces to the proper number—six, which, if three of the six swarms' queens have been spared, may be joined to the old stock it issued from after the queen cells have all been destroyed. Six extra strong hives will now be the result, and three of them prodigious ones; but none of these having young queens it will be as well to divide one of the old stocks into six or seven nuclei. After these have been duly fertilised and breeding for some time overhaul the first named, depose their queens, and join nuclei in the usual manner, but not before removing excess of drone comb and what

sealed honey ones that can be spared to make room for combs of the nuclei. The total number is now reduced to six again, and every one is in the very best condition for stocks the coming year, or for the approaching Heather harvest; and if the Clover harvest has been one of sunshine the yield will be something great, as will also be the six stocks, as they have the brood of two queens; so that in addition to having the bees of one queen only, which in itself would be a populous hive, there is the nucleus extra, and its young queen should gather double the quantity of honey than any hive not similarly treated. Should an increase of stock be desired there is no better plan than that of dividing into nuclei after the issue of the first swarm, and if my instructions previously given are followed there will be but few condemned or surplus bees, and no brimstone pit, with the largest yield of honey that possibly can be secured.

A young queen at the head of each stock about the 20th of July, swarming is not so liable to take place, but to avoid that it may be necessary to add an extra division underneath the usual body boxes. I have had similarly treated hives gather 20 lbs. honey daily during the glut. By pursuing the above plan we get the greatest number of bees at the right time, and there is an end to all bother after the surplus honey has been secured, and by using the carbolicised paper, the removing of the supers is but the work of a few minutes, without the risk of starting robbing, or getting supers spoiled by the bees breaking the seals of the honeycomb, as is usually the case when the supers are removed during a dearth of honey. The Americans seem not to understand this easy mode of removing supers, as they are only discussing the subject which is the best way to remove, not knowing the easy method of—

A LANARKSHIRE BEE-KEEPER.

THE COMBINATION OR LONG-IDEA HIVE.

SEVERAL have been inquiring about this hive lately, and as I have had over thirty of them nearly always in use for seven years, I should be able to discuss their merits and defects. The principle of the hive dates long back, but it was first brought prominently before modern bee-keepers by Captain Adair in the United States; bee-keepers there lost their heads over it, and began calling it the "Long-Idea" hive. This was some time before it was "originated" here. The best feature about this hive is it can be made from almost any kind of packing box that happens to be large enough; and under the name of the Excelsior hive some years ago I gave directions in another journal that enabled anyone who could drive a nail or cut a piece of wood to make them. This feature is the only advantage it has over other good types. Comparing it with the Cowan types, it has the advantage of contraction to any comb, or the expansion longitudinally to any number, limited, of course, to the length of the hive. It is solely on account of this peculiarity, erroneously supposed to be an advantage, that this type of hive has become so popular, particularly amongst those who think continuous manipulation the proper way to manage a stock of bees. "Lanarkshire Bee-keeper" describes it as the best non-swarming hive, as nearly all the bees have died in them this summer. Allow me to remark that it was not the hive which caused the bees to die, it was this manipulation. Being so handy for the purpose, its owner is forever pulling the combs about, spreading the brood, and chilling it. When he has done the bees have to rechalk the dummy to stop the draughts, and get up the heat internally; this means a waste of stores and energy, when in a season like the past they were bound to starve, while other stocks, kept as compact as possible without being disturbed, prospered.

One great drawback to the system is the brood is spread out flat instead of being square or round on the base, and rising upwards in a natural manner as in the Stewarton system. Many think this an advantage, and if there was any truth in the teaching "that shallow hives were best for comb honey," this hive should give a splendid return if headed with an extra prolific queen, but as a matter of fact storified hives with deep broad nests have always outstripped it in this respect.

When it was introduced it was claimed as a fact fully established, that bees would invariably store their honey in the farthest point from the entrance, hence they would always store their honey in the back combs, which could be taken out, extracted, and returned without touching or moving the others. My seven years' experience proves to me that bees invariably place their ripe honey above the brood, and that I was just as likely to find the front combs filled with honey as the back ones. This, it will be seen, involved much labour. During a good honey flow I have always found the combs sealed above, and the brood gradually crowded down to the bottom, even with plenty of room behind, so that very rarely indeed did I get combs to extract free from brood. Up to this time I had always looked upon the storifying system

with horror. I could not see how bees could be kept from "boiling out" from the divisions in anger, and how to quiet them seemed an unsolved problem; for though "Lanarkshire" and other Scotch authorities spoke often of lifting a super up and putting another under, no one has ever explained, to my knowledge, how with both hands holding a super, say 30 lbs. weight, he kept the bees quiet in both super and stock. With this idea I decided to limit the brood frames in my long hives to about a cube, and place supers on the top, intending to work them from above as before. I was not long in noticing that the bees improved more rapidly in strength, more honey was stored in these supers than other stocks equally strong stored in unsupered long hives, and to my bewilderment they began to show signs of requiring more room. With a cluster of bees hanging from the entrance as big as a bucket, the super full too, and the stock crossed Syrians, and rather cross, I quite expected a lively time over putting that other super under the other. I decided that smoke or carbolic acid was out of the question till the work was done. I arranged my empty super, then I lifted the full one off, covered with the quilt, set it on the top, and then set the two on the top of the brood frames as quickly as possible. I never felt so surprised as to see the bees really frightened instead of angry, and not one took wing. This experience inspired me with confidence to do others likewise. I now began to see the beauty of the storifying or Stewarton system, and since then I have quite tested it, and I have always found that if a super is lifted off, covered with the quilt or other cover, the bees are more frightened both in the super and the hive below than they can possibly be by any other means. There is no "boiling out," and not a bee need be crushed. I am rather surprised those who have practised the Stewarton system have not made frequent notice of this. They have talked often enough about doing it, but never explained how easy it was, and I must candidly confess I never could regard it as a simple matter. I have lifted thousands of skep hives off their stands, and opened many more moveable comb hives from above, and I always have found bees ready to resent abrupt interference. So singular is this, I have been trying to think of a natural solution. Here is the way I explain it. It is natural for a bive to be turned over by a bear or other animal, or disturbed from the top, hence they are always ready for attack from these places, but to be suddenly divided in the middle of their home is not natural, and puts them in the greatest fright.

Speaking of the storifying system, a writer says in another journal "That we have to pull the whole pile down to get at the bottom combs." To show how far he is from the truth let us imagine a stock piled up ten storeys high and we want the middle comb out of any one, say the bottom one; well, all we have to do is to lift off the nine top storeys at once, and we are at it in a moment. More than this, if we wish to know how they are going on in the middle—say to see if the young queen is laying, or if queen cells are being formed, we just turn up the upper storeys and see. No need of smoke, as the bees at once run to the honey to fill themselves, leaving the bottom edges of the combs bare. As the principle for a migratory bee hive it seems to be just the thing, as all superfluous storeys can be left at home.

It is when we use the longitudinal hive for migratory purposes that we understand and comprehend the meaning of its name, "Combination Hive." We are bound to take more hives than the bees require; this adds weight in lifting, loading, packing, and carriage; it makes the hives even difficult to pack on drays for safe riding. Then there is the packing up; probably the dummy has shrunk, and the hive walls expanded through wet, or the floor board has warped a little; and if so there is a job of caulking the crevices with rags and the screw-driver to keep in the bees. And when all have been carefully done the chances are that bees will be found escaping in at least three out of every twenty as soon as the dray begins to move. Its name is very appropriate, as it combines the maximum of trouble and expense with the minimum of returns.

This is what I am convinced of much against my will. I have not found placing the frames across the entrance to make the least difference, either in winter or summer, so long as the queen was well bred; but it is easier to get ill-bred queens in these hives than good ones, hence the apparent difference by those who have tested the two systems, right-angled combs v. crossways combs to entrance.

Allow me in conclusion to point out that in a few years every bee-keeper will send his bees to the Heather; that being so, the one who is thinking of buying a hive will be wise to look round for one adapted for migratory purposes. Certain it is the necessary qualities will not be found in the "Combination" or "Long Idea" type.—A HALLAMSHIRE BEE-KEEPER.

BEES.—A QUERY.—Can any of your bee-keeping readers say whether single Dahlia blossoms are injurious to bees? I have heard they are very bad for bees. I have quantities of Dahlias and Tritomas, and the blossoms are always full of bees.—MILWARD, *Lavistown, Kilkenny*.

INTRODUCING QUEENS BY THE HALLAMSHIRE LAW.

I AGREE with "Felix" that the past season has been a poor one for queen-rearing, and one that has been unfit for much manipulation; but I feel disappointed that he has not thoroughly tested the Hallamshire law; and as the time is near when it may be tried by exchanging every queen in one's apiary, I will undertake to replace every queen he loses in making the experiments. Each queen shall be bred in 1888 or 1887.

Also, should anyone desire to test the law, and loses a queen over it, I will undertake to furnish a queen, as above, for each one lost in strictly obeying the rules laid down in the Hallamshire law.

NOTE.—The authorities (?) say it is next to impossible to introduce queens in the fall.—A HALLAMSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Lambert & Reiter, Trèves.—*General Catalogue*.
L. Späth, Berlin.—*General Catalogue*.
Webb & Sons, Wordsley, Stourbridge.—*Catalogue of Selected Seed Corn, 1888-1889*.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Tea Roses (T. W.).—The information you require will appear in an early issue of this Journal. You will be able to grow them readily as you suggest.

Mushroom Spawn (T. R.).—It appears to be good spawn. You cannot do better than follow the instructions you have already received; the information in the book is thoroughly reliable.

Ferns in Case (E. D.).—Too much light and too little ventilation will make the fronds turn brown. Our Fern case never has the sun shining upon it, and has the sides slightly open all the day and night.

Mildew (Anxious).—Probably the other plants will be affected also, and the best plan would be to remove those already attacked if it is convenient to do so. You do not say what plants you have, nor where they are growing.

Cracked Pears (G. J. S. and W. M.).—The cracking of fruit has been unusually prevalent this season, and is no doubt due to the continuous rainfall. There is no remedy for injury already done, and it is to be hoped that another season the weather may be more favourable.

Cost of Preparing Land and Planting Fruit Trees (G. M.).—The cost of trees for an acre of land obviously depends on the kinds and numbers intended to be planted. Mr. Rivers, in his Conference paper, states the number of trees of different kinds for planting a rood of land (see page 235), and their cost can be obtained from catalogues. In the same paper the cost of preparing land for their reception is also given by the rod and rood, and you can easily calculate the amount per acre on the data there given.

Beans in Pods (J. W.).—The old story of Beans "growing wrong end upwards in pods this year" is repeated every season, but no samples are sent. When the pods point upwards the eyes of the Beans are naturally in the same direction, and when the pods hang down the eyes look down too; but they are quite right all the same, just as those of their observers are, whether they turn them upwards to the sky or downwards to the earth. The pods of some varieties grow more or less erect, while others as naturally hang down to a greater or less extent, the drooping tendency increasing with age; but there is nothing unnatural or abnormal about any that have come under our observation.

Edging Plants (W. R. S.).—The following are good edging plants:—Ajuga reptans rubra, dark purple leaves; Arabis alpina variegata aurea, Aubrietia purpurea variegata, Cerastium tomentosum, Euonymus radicans variegatus, Iberis sempervirens fol. var., Sedum acre variegata, Sempervivum californicum, Stachys lanata, Stellaria graminea aurea, and Thymus citriodorus aureus, all of which are hardy. The following are more or less tender:—Iresine Lindenii, Peristrophe angustifolia aureo-variegata, Sedum Sicboldii medio-picta, Mesembryanthemum cordifolium variegatum, Gnaphalium lanatum, Leucophyton Brownii, Alternantheras, Echeveria secunda glauca, E. pumila, Alyssum variegatum, with Lobelias and Golden Feather Pyrethrum.

Trees for Screen on the Seacoast (M. S.).—There is no evergreen tree so suitable as *Pinus austriaca*, and it is equally serviceable inland, thriving in the bleakest situations and at high altitudes. We should plant a good width of *Pinus austriaca* near the sea, then an inner one of Sycamore, having Holly for undergrowth, which should be planted so that the Sycamores will ultimately be 24 feet apart every way, and the Hollies 12 feet, planting the Hollies at those distances apart in the first instance, and the Sycamores 4 feet. Inside you can have most kinds of deciduous trees and shrubs, also evergreens, Conifers doing remarkably well.

Ventilating a Conservatory (R. O. S.).—The system of ventilation requires to be the same both in summer and winter—viz., air should in the first instance be admitted by the top lights, but the time of doing so will entirely depend upon the temperature and the time of year. In the winter season, or from October to March inclusive, commence ventilating by the top lights when the temperature reaches 50°, increasing the admission of air with the increase of sun heat, and open the side lights. The ventilation should be reduced by closing the side lights in the first instance, and finally the top lights when the temperature declines to 50°. In summer the same conditions are to be observed, only the temperature should be kept at 60° to 65° through the day, observing the same rules as to commencing and closing the house. The temperature in winter should be 40° to 45° at night, and 45° to 50° in the daytime, by artificial means, which will be considerably advanced by sun heat, and in mild weather. Fire heat will only be necessary to maintain the temperature named, and to expel damp, when the fire should be lighted in the daytime and ventilation given.

Cinerarias Dying (Anxious).—Cinerarias "go off suddenly" from various causes—grubs or wireworms in the soil, too loose and rich soil inducing succulent growth in the early stages, allowing the plants to become much root-bound before repotting, permitting the sun to strike on the pots, thus scorching or withering the roots, an excess of stimulants, with faulty watering generally. Growers of Cinerarias for market do not lose one out of a thousand, and they pot much more firmly, using good "wearing" soil, than is customary in many private gardens, though in by no means all. The plants then grow steadily and sturdily, producing medium sized leaves of great substance that do not flag under a few gleams of sun, and it is rare for plants so grown to collapse in the manner indicated, always provided the soil is free from worms and other pests injurious to the plants. Cinerarias raised early in spring are more liable to "go off" than those raised later—in May or June.

Charred Garden Refuse (O. C.).—It is valuable for gardens, and may be prepared as described in our manual on manures, from which we cite the following:—"To char turfy soil the best method is to cut it into sods of about a spade's width and 2 or 3 inches thick when the soil is not over-saturated with moisture. Burning any kind of material, and allowing it to be consumed, producing nothing but smoke and ashes, is a real waste of valuable substance which could be turned to beneficial account for the culture of the soil. Commence by placing a small quantity of combustible material, such as dry weeds, hedge-trimmings, furze, heath, shavings, brushwood, or bushes, or any kind of dry vegetable refuse the place produces near at hand; then commence packing the sods, no matter how or what thickness, as any thickness may be charred by placing amongst them as the heap or kiln is proceeded with some one of the before-mentioned materials, or old tan or sawdust, just to keep the materials ignited. It is no matter how large or small the kiln may be formed, for this may be regulated by the convenience of the material at hand and the quantity of charred materials required; only, when the kiln is formed it should be slightly covered or eased with fine earth to prevent the fire from flaring and to maintain a steady, smouldering, charring or roasting. Much smoke will escape for a time, and when the smoke begins to subside it is a sign that the materials are charred enough. The fire should then be smothered by easing up the outside of the kiln quite close with earth. Although turf sods only are mentioned, the same process of charring may be carried out with weeds and other garden refuse if the outside of the heap is covered over closely with sods of earth, so as to exclude the air sufficiently to ensure the burning to be very slow and smouldering."

Fruit Preserving (Inquirer).—The information you require is probably contained in the following remarks by Mr. Beach at the recent Crystal Palace Conference of fruit growers. "On the Right Hon. Lord Sudeley's fruit farms the fruit is picked in the early hours of the morning by a number of women, who come from the neighbourhood of Staffordshire, who are glad to have the opportunity of obtaining labour in the open air. At eight o'clock A.M. a number of workpeople also arrive from the surrounding villages; these, with the other workpeople, number about 500 hands. The hands from Staffordshire are lodged on the plantation, as, of course, the distance from their homes is too great. The hour for the first delivery of fruit to arrive at the factory from the plantations is eight o'clock A.M. This may consist of Strawberries, Red and Black Currants, Raspberries, &c. These kinds are picked free from the stalks on the plantations, therefore the fruits are ready at once for the boiling pan, and thus retain their freshness and flavour. This goes on without intermission, with the exception of meals, about every two hours during the day, the average quantity of fruit gathered being about 15 to 20 tons daily. Should the fruit come into the factory in larger quantities than can conveniently be made at once into jam, it is put down in large stone bottles and casks, perfectly air-tight, for future

use, this process being known as 'pulping,' the fruit turning out when required in mouths' time as fresh and bright as if recently gathered. This, of course, only applies when the fresh fruit is at once attended to, as every hour makes a difference to its appearance after being picked. The sugar used in the manufacture of these jams is known in the market as the 'White Dutch crushed,' and no other kind or any other substitute, such as glucose, &c., is allowed. There are sixteen steam pans in use, each capable of turning out 1 ewt. of jam every eight or ten minutes, or at the rate of about 40 tons daily. At the works a new venture is also being tried by drying the fruits in the same manner as the Americans. There are two No. 3 patented American evaporators, capable of drying about 40 bushels of Apples on fifty trays in each, the process taking about three hours. The greatest difficulty seems that the English Apples being smaller than the American ones, after paring and coring, there is not sufficient to compare in size, when made into rings, with the Americans, but no doubt the flavour of the English would be superior. These machines can also be utilised for drying Plums, &c., when there is an abundant season; and, as one of the gentlemen yesterday remarked, there are quantities of Plums rotted upon the land some seasons for want of a market. There is also a large evaporating room erected similar to those on the Continent, for the purpose of drying prune Plums. This is capable of drying from one to two tons at one process."

Keeping Black Hamburgh Grapes (R., Surrey).—The Grapes that have been ripe now for six weeks will not keep so long as those that are ripened about this time, as the sun has much power in late August and early September, and acting on ripe thin-skinned Grapes, such as the Black Hamburgh, prejudicially affects them—not infrequently causing those that were jet black when first ripe to assume a reddish hue. When this takes place the Grapes are not only deteriorated in appearance, but the flavour is impaired and their keeping qualities considerably reduced. In order to insure Black Hamburgh and other thin-skinned Grapes keeping well they should be ripened beneath a good spread of foliage, yet not so crowded as to interfere with the free admission of light and air to the principal leaves. The Grapes not only colour quite as well, but the foliage prevents the sun from rendering them over-ripe, or at least prevents their losing colour—a sure indication of their days for keeping being numbered. As your Grapes have already begun to "mildew," which we apprehend is to decay and become mouldy, we think they will not under any circumstances keep long, probably not more than a few weeks. We presume you are fastidious in removing decayed berries as they appear, the bunches being examined frequently for the purpose, and every berry in the least decayed removed. This is absolutely necessary. Instead of firing at night, as a rule you should have fires in the daytime, and then ventilate freely, the heat being afforded early in the day and turned off so that the heating medium becomes nearly cold before nightfall. A little air may be given at the top of the house, which will prevent the deposition of moisture through the night; but when the weather is wet the house should be closed day and night, a gentle fire heat being employed to keep the air buoyant, and if moisture accumulates on the inside of the glass admit a little air by the top and bottom ventilators to dispel it. A moderately moist atmosphere is not injurious to Grapes keeping, provided it is not stagnant. The temperature by artificial means ought not to exceed 50° at night, and above this in the daytime air should, whenever the weather is favourable, be freely admitted. It will be advisable to cover the inside border with dry mats to prevent the evaporation of moisture from it, and the outside border should be covered with shutters to throw off the wet. The Grapes will keep better after the foliage begins to fall if they are cut with as much wood as can be spared, and the shoots inserted in bottles containing clear rain water with a few pieces of charcoal in each, the bottles being fixed in an inclined position so that the bunches will hang clear of the bottles. A dry and cool fruit-room is a suitable place, the Grapes, from the more equable temperature, keeping much better than the variable temperature and moister atmosphere of a vinery. We have cut excellent Black Hamburgh Grapes through December, and occasionally had very good bunches in January but they were not ripe until towards the end of September.

Mixing Soils (J. Manton).—Undoubtedly the practice is good when judiciously carried out, and upon the subject we have nothing to add to the following excellent remarks of Mr. Cuthbert Johnson:—"I have witnessed, even in soils to all appearance similar in composition, some very extraordinary results from their mere mixture. Thus, in the gravelly soils of Spring Park, near Croydon, the ground is often excavated to a depth of many feet, through strata of barren gravel and red sand, for the purpose of obtaining the white or silver sand which exists beneath them. When this fine sand is removed, the gravel and red sand are thrown back into the pit, the ground merely levelled, and then either let to cottagers for gardens, or planted with forest trees. In either case the effect is remarkable, all kinds of either Fir or deciduous trees will now vegetate with increased luxuriance; and in the cottage gardens thus formed, several species of vegetables, such as Beans and Potatoes, will produce very excellent crops, in the very soils in which they would have perished previous to their mixture. The permanent advantage of mixing soils, too, is not confined to merely those entirely of an earthy composition. Earths which contain inert organic matter, such as peat or moss earth, are highly valuable additions to some soils. Thus, peat earth was successfully added to the sandy soils of Merionethshire by Sir Robert Vaughan. The Cheshire farmers add a mixture of

moss and calcareous earth to their tight-bound earths, the effect of which they describe as having "a loosening operation"—that is, it renders the soil of their strong clays less tenacious, and, consequently, promotes the ready access of the moisture and gases of the atmosphere to the roots. The cultivator sometimes deludes himself with the conclusion that applying sand, marl, or clay, to a poor soil, merely serves to freshen it for a time; and that the effects of such applications are apparent for only a limited period. Some comparative experiments, however, which were made sixteen years since, on some poor, hungry Heath land in Norfolk, have up to this time served to demonstrate the error of such a conclusion. In these experiments the ground was marled with 20 cubic yards only per acre, and the same compost, it was then planted with a proper mixture of forest trees, and by the side of it a portion of the Heath, in a state of nature, was also planted with the same mixture of deciduous and Fir trees. The growth of the trees has been there rapid and permanent, but on the adjoining soil the trees have been stunted in their growth, miserable in appearance, and profitless to their owner. Another, but the least commonly practised mode of improving the staple of a soil by earthy addition, is claying, a system of fertilising, the good effects of which are much less immediately apparent than chalking, and hence one of the chief causes of its disuse. It requires some little time to elapse, and some stirring of the soil, before the clay is so well mixed with a sandy soil as to produce that general increased attraction and retentive power for the atmospheric moisture which ever constitutes the chief good result of claying poor soils. Clay must be, moreover, applied in rather larger proportions to the soil than chalk, for not only is its application rarely required as a direct food for plants for the mere alumina which it contains, since this earth enters into the composition of plants in very small proportion, but there is also another reason for a more liberal addition of clay being required, which is the impure state in which the alumina exists in what are commonly called clay soils.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*Novice*).—1, Belgian Purple; 2, Bradshaw; 3, Prince Engelbert; 4, White Magnum Bonum; 5, Hesse; 6, Royale Hâtive. (*S. Birmingham*).—The Pears had no numbers attached, but the globular fruit is Ne Plus Ultra Meuris, the other we do not recognise. (*H. M.*).—The Plum is Goliath. (*C. L.*).—The Plums should be accompanied by specimens of wood and foliage. A box of fruit has been received without any letter or indication where it is from. The Peaches are No. 1, Violette Hâtive; 2, Teton de Venus; 3, Barrington; 4, Dr. Hogg. The Cherry is Belle Agathe, and the Apple is not known. (*S. S.*).—Red Autumn Calville. (*G. L. Court*).—Marechal de Cour. (*W. II.*)—1, Fondante d'Automne; 2, Gansel's Bergamot; 3, Souvenir du Congrès. 4, Nouveau Poiteau. 5, Comte de Lamy. (*Dr. Lowther*).—2, White Paradise; 4, Yorkshire Greening; 5, Chaumontel. The others we cannot identify. (*Ribstone*).—3, Minshall Crab; 8, Court Pendu-plât; 9, Dutch Codlin; 11, Federal Pearmain.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes, slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W.*).—*Spiraea callosa alba*. (*J. R.*).—*Euonymus japonicus argenteo-marginatus*. (*J. C.*).—It is a *Hæmanthus*, but the flower was in a state of decay when it reached us. (*R. O. M.*).—1, *Aster bessarabicus*; 2, *Helianthus multiflorus*; 3, *Papaver nudicaule*.

COVENT GARDEN MARKET.—SEPTEMBER 26TH.

OUR market is now overstocked with Peaches, with difficulty clearing at low prices. Cobs down in price.

PROGRESS.

SWEET are the lessons of adversity when so applied as to ensure prosperity in the future, and there is ample evidence on all sides that the stern teaching of the agricultural depression has and is leading to a marked improvement in practical farming. The agricultural Press teems with instructive articles calculated to render farmers more hopeful, and if possible more energetic. A calm reasonable view of the situation has brought conviction to the minds of all sensible agriculturists that a prosperous future is possible. There are not wanting many who cry out about the risk of disaster from a wet summer, while others of a cynical disposition indulge in a sneer at landlords farming, and much grumbling at the condition of things in general.

Speculative farming as a remedy for hard times, such as the cultivation of Sugar Beet, Tobacco, Flax, fruit and vegetables has in most cases ended disastrously. Fruit and vegetables, if local conditions are favourable, undoubtedly answer well under skilful intelligent management, and it is precisely the absence of these qualifications which so often leads to failure. Take the examples of either fruit or vegetables to be seen in most provincial markets; few, if any of them, are really good, and there can be no doubt that superior goods would command a ready market. In proof of this we may mention a case which came under our notice many years ago. The produce of a large private garden noted for its excellence was for certain reasons thrown suddenly upon the market of a large town where there was already an apparently superabundant supply, but the superiority of the goods from that garden ensured a brisk sale and higher price than ordinary market rates. The moral is plain enough; if a farmer thinks of turning part of his farm into a market garden let him consider well whether he has sufficient skill and capital for the production of a really first-class article, and if the conclusion be at all doubtful let him confine his efforts to the cultivation of crops which he really understands. We once heard an excellent farmer of considerable local fame as a breeder of choice horses and bullocks declare that he had

also tried fruit farming, and failed to make it answer. When the worthy man went on to condemn fruit farming altogether with an air of conviction we felt a strong desire to test his knowledge of such work, as might easily have been done by a few leading questions.

Of Tobacco, the difficulty appears to lie in the manufacture rather than in the cultivation, and those gentlemen who have made the attempt to introduce its culture as a new farming industry into this country would have saved much time and money had they first of all become thoroughly acquainted with the process of its manufacture. Mr. H. T. Rathbone has recently written to the *Times* from Ireland to complain, that being an owner and occupier of land, and seeing the impossibility of competing with the foreign producer of corn, he had taken to Tobacco growing, but because he would not undertake to promise to pay a duty of 3s. 2d. per lb., the Excise had the plants destroyed. If the loss of his Tobacco only leads him to try and improve his corn growing, he will not have much reason for regret. In pleasing contrast to this letter was another, telling of a carefully planned and successful attempt at the selection and improvement of Kerry cattle; of cows with an average of 504 gallons of milk yielding 12 per cent. of cream. The plan adopted for this herd was to purchase a considerable number of young beasts, to select the most promising as they came into profit, to discard all inferior animals, so as subsequently, by breeding and selection, to improve the breed up to a given standard.

In the general cultivation of farm land it is now fully established that success depends upon high culture, for which there must be sufficient capital, and then the matter is a certainty. But too often tenant farmers' capital falls far short of the proverbial £10 per acre, yet we know that even twice that amount may be invested to advantage upon corn farms. That very successful farmer, Mr. John Prout of Sawbridgeworth, has employed £20 per acre, and he has proved that yield and expenditure have more effect upon profit than the price of corn. Professor Elliot has recently, in the 'Land Agent's Record,' given proof that high farming, by producing increased quantities, is able to compete with lower prices. He says distinctly that, "Since the repeal of the Corn Laws in 1846, the English land occupier has been compelled to compete with a large and constantly increasing import of corn, the effect of which has been to lower very considerably the value of English produce. In order to meet this the English farmer must increase the produce of his land; this can only be acquired through the expenditure of extra capital in keeping the land clean and in a high state of cultivation." Fortunately for the farmer, increased quantity in produce has been proved to be equal, if not, in fact, to cover low prices.

WORK ON THE HOME FARM.

With fine settled weather the corn harvest is now going on with greatly improved prospects. Bright sunshine is eagerly welcomed and turned to account to render Peas especially ready for carting. Much Barley, too, among which there is a strong growth of Clover, has been turned as repeatedly as if it were being made into stover, which in point of fact the straw and Clover will be. If this weather continues after the corn is all mown second growths of Clover and Sainfoin will be mown also, the first for stover and the last either for stover or seed, according to its condition. Much corn has been threshed as it was carted from the fields during the last few days, and samples for sale have been plentiful at market. New Wheat has fallen to about 30s. per quarter, and very little Barley has reached a higher price. The regular Barley trade has hardly begun as yet. We have threshed none, and cannot offer an opinion as to quality other than that malting Barley must be decidedly inferior to that of last year.

We have had a little Wheat threshed of necessity, as we ran short of straw for thatching the corn stacks. The yield was so far satisfactory, being fully up to 40 bushels per acre. Light land farmers complain of a falling-off in weight in the Wheat of this season, but it by no means follows that this will be the case generally. We have seen it stated authoritatively that the Wheat grown this year is very inferior to that grown last year, and it will make at least 5 per cent. less flour and consequently 5 per cent. less bread. Present prices afford no real test of this, for it is the farmers' necessity which caused them to thresh and flood the market with samples. Full advantage is taken of this by the middlemen. If there be any truth in the premise that there will be

an actual deficiency of 16,000,000 quarters of Wheat in the world's supply this year prices must rise eventually to a height unknown in recent years, and we shall certainly hold over the Wheat as long as possible. So we advise our readers to thresh only what is wanted for seed and wait.

IMPORTANT TO FARMERS AND OTHERS.—At the Spilsby petty sessions held recently, John Rowland Payn of Sibsey, farmer, was charged with supplying beer to labourers in his employ as part payment of wages. Mr. Gane appeared for the defendant. According to the evidence George Sands, John Bishop, and Edward Semper undertook to cut a piece of Oats for the defendant at 12s. per acre, after asking 14s. The point in dispute was, whether the beer supplied, half a gallon per man per day, was included in the bargain or whether it was the generosity of the defendant, who, it was stated, had said that if the work was done well he should not be particular to some beer. For the defence, the men affirmed that the beer was not mentioned until the bargain was concluded, and they were perfectly satisfied with the price agreed upon independently of it. The prosecution alleged that the beer was a consideration in the agreement, and with that view the Bench concurred, and fined the defendant 6d. and £1 7s. 6d. costs, as this was the first case under the new Act (the Truck Amendment Act, 1887) before them. It may be added that these Acts apply to all working-men called artificers, but not to domestic servants. A farmer, as employer, may pay his men partly in money and partly in food, cottage, or anything else they may agree upon, except intoxicating drinks, because the Act says he shall not contract to supply them with intoxicating liquors in addition to wages as a remuneration for services.

HAY-DRYING MACHINE.—Mr. W. Kruse writes: "In reply to the request on page 256 I may say that I do not know Mr. Gibbs' address, but it may help your correspondent if I mention that a notice of Mr. Gibbs' drying machine appears on pages 36 and 57 of the *Journal of Horticulture* for January, 1881.

OUR LETTER BOX.

Ensilage (S. O.).—The sample sent is an excellent one in all respects, and we shall be glad to learn your method of preparing it. The notes on Potatoes would be useful, and we are obliged to you for the offer.

Manure for Wheat (A. J. C.).—In autumn $\frac{1}{2}$ cwt. nitrate of soda, $\frac{1}{4}$ cwt. steamed bone flour, $\frac{1}{4}$ cwt. superphosphate. In spring $\frac{1}{2}$ cwt. muriate of potash, $1\frac{1}{4}$ cwt. nitrate of soda, $1\frac{1}{4}$ cwt. steamed bone flour, $\frac{1}{2}$ cwt. superphosphate.

Land for Permanent Pasture (A. D.).—If you can get the land clean in time for Wheat sowing, give preference to that crop; if not, sow the grass seed with Oats in spring. If when the Oats now being cut are carted the weather continues fine, plough at once, harrow next if the land is foul, and then cross plough. Or if you have a horse-hoc scarifier, ducks-foot harrow, or cultivator, the work may be best done with some such implement rather than by a second ploughing. If the land is hard and the clods contain the roots of perennial weeds, a heavy roller may be used with advantage. A spring surface dressing of artificial manure when the grass seed is sown will suffice.

REMARKS.

16th.—Generally overcast, but a little sun early and at midday.

17th.—Cloudy except for an hour at midday.

18th.—Bright in early morning, and cloudy during day.

19th.—Fine and bright all day, almost cloudless moonlight night.

20th.—Fine and bright throughout.

21st.—Overcast early, cloudy morning, bright afternoon and night.

22nd.—Fair morning fine bright day, and brilliant night.

Another fine week, less rain, and with temperature above the average.—G. J. SYMONS.

CLEAN CELERY.

IN numerous instances the rows of Celery are strong and well grown, only to be much damaged and disfigured by slugs. Where only just the heart is used it does not so much matter, but even these are sometimes reached by slugs, and none of us like to see much mutilated Celery lifted. If the whole or only a portion of the crop is marketed there is still greater necessity for protecting the outer stalks in some way, as all who buy Celery like to have plenty for their money, the value of each "stick" being decided according to the bulk of blanched outer stalks rather than the quality of the heart.

After trying various systems of growing Celery, more especially as regards the size of trenches and the number of rows that can be grown in each, I have long since arrived at the conclusion that single rows are the most profitable in the end, as it is possible to grow nearly as many plants in that way as can be done when double lines are placed in a single trench; not only can the finest Celery be grown in single rows, but these can also be more easily earthed up and better protected from slugs than can two or more rows in a trench. According to my experience heavy or moderately heavy lands can with very little trouble be made to produce Celery of the best quality, but unfortunately such soils are invariably the most infested with slugs. It is therefore in the process of earthing up that the greatest judgment must be exercised and the greatest pains taken, or what would have been very fine Celery will be completely marred quite early in the season.

In the first place it is a mistake to be in too great a hurry to complete the earthing, this giving the slugs good shelter and plenty of time to spoil the stalks. When the plants are well advanced and growing strongly, enough soil should be broken down and well worked round the plants, this acting as a mulch and also serving to prevent the outer leaves assuming a horizontal position. Two other earthings ought to be sufficient. If the second is given before the hearts are far advanced the mass of earth wedged against the stalks will effectually check their proper development. Better, therefore, to underdo rather than overdo it. The final earthing up must be done before severe frosts are anticipated, and only the very latest ought to be left till early in November. The ridges enclosing the Celery should be finished neatly, so as to throw off as much water as possible; and if only the best portion of the leaves is unburied a moderately severe frost will do but little harm.

Having briefly alluded to the manner of and time for earthing, it yet remains to be told how the Celery is to be kept clean, that is to say, but slightly disfigured by slugs. Where only a small number of plants are grown the simplest plan for preserving and effectually blanching the stalks of these is either to enclose each plant in a 5-inch drain pipe, or to wrap them round with two or more folds of strong brown paper. The former must be set over the plants fairly early, or when the leaves can be passed through without being damaged, but the brown paper may yet be used. At one time paper collars, invented by Mr. J. Simpson of Wortley Hall Gardens, could be purchased, and these answered very well, but would have been better if somewhat larger in size. These fastened with hooks and eyes, but the strips of brown paper used as good substitutes for the collars require to be fastened with strips of raffia. They must not be too tightly bound round the stalks, or the hearts will be unduly confined, and both paper or

pipe-covered plants should be earthed up for the winter, the first soil being worked in early, and a final earthing given after the plants are fully grown. Few need to be told that Celery requires plenty of rich food and moisture at the roots, and deferring earthing up admits of liquid manure or water being applied quite late in the season. In very many instances the Celery is much too dry at the roots when the soil is placed round the stalks, and unless the autumn is exceptionally wet it is a long time before the rains benefit the crop. It is dryness at the roots that more often than not is the cause of premature bolting or running to seed, few being aware or taking the trouble to ascertain that the soil underneath could possibly be so dry with so much earth on the top of it. Even in such a wet season as that just passed through we found it necessary to give the rows of Celery a good soaking of water prior to commencing earthing up, and more had to be given at the second time. If this was necessary in our case it must have been most imperative where the subsoil is of a gravelly nature, ours being solid clay.

Those who devote much ground to Celery culture cannot afford to coddle it, and must perforce adopt some rough and ready methods of checking the slugs. In some instances a liberal application of soot, or soot and lime about the plants and among the soil, as it is worked round the Celery, helps to make the latter distasteful to the slugs and the quarters too hot for them. Soot especially is a good fertiliser, and though those who prepare the Celery for the table grumble at having it so black, it ought yet to be extensively used. On light soils a sprinkling of salt is also a preventive of slugs and acts as a fertiliser, but it must not come into contact with the leaves. The surest way of keeping Celery clean is to quite surround the stalks with fine burnt clayey soil or sifted ashes from coal fires. Both, in moderation, greatly improve heavy land, and the process of surrounding the Celery with them is not so tedious as might at first sight appear. It need not be used at the first earthing up, and enough may be worked in at the second time to quite answer the purpose for which it is added. The first proceeding should be to well gather the outer stalks together so as to effectually shut out any soil or rubbish from the hearts, the ties being made rather high up, or where they can be loosened again. A long board of any width may next be set on each side of and nearly close to the rows of Celery, and kept in position, if need be, with stakes fixed inside. Against the boards bank up the soil, and then fill in the space kept by the boards with either the burnt soil or ashes. The boards may then be drawn up, refixed, and a second layer of soil and other material added as before, or this may be delayed, if the Celery is backward, for another ten days. All may be finally banked over with soil. Thus treated, the Celery is less liable to decay during a cold wet winter, and invariably turns out clean and good.

I ought perhaps to add it is of the greatest importance that the heart be always well protected with the outer stalks while the process of moulding up is going on, and this can be done either by lightly tying them up with raffia or strips of matting, which must be taken off again, or one person may hold the stalks together while others are chopping down and working in the soil.—
A VEGETABLE GROWER.

LIFTING AND REPLANTING OLD VINES.

I INCLINE to think the present is the best time of the whole year to carry out the above operation, as if lifted now it gives the Vines ample time to recover before shedding their leaves, and with careful management they may be made to produce a satisfactory crop of well coloured even bunches of Grapes the following year. I consider it a sheer waste of time heavily top-dressing yearly when once Vines show signs of distress and the shanking of the berries takes place. These annual top-dressings are undoubtedly highly beneficial to them when in a flourishing state, as it both

encourages plenty of healthy top roots and keeps them in good order for many years, but when this fails it is evident something more is needed to renew their vigour, and the only way is, in my opinion at all events, to dig them up and replant them in a fresh, sweet, suitable compost. In 1885 I lifted a house of Muscat Vines here, which for several years shanked badly, with the result that the following year I was rewarded with a good crop of medium bunches which finished well. The year I lifted them I was unable to cut a creditable bunch out of the whole house, and notwithstanding their old age they have wonderfully improved since the operation, and are now in a very satisfactory condition. I do not prefer the above plan to that of planting healthy young Vines, but it must be borne in mind there are some who do not care to have their old favourites destroyed, which have for many years yielded satisfactory crops of Grapes. Therefore it is to improve these I wish to recommend the lifting process.

The house of Vines referred to was dug up on the 1st and 2nd of October in the following manner. A trench was dug opposite the Vines, using for this purpose four-tined forks; all the soil was carefully removed, and every precaution was taken not to damage the roots more than possible. We found, however, very few of these for some time, but on approaching the stems of the Vines I was not in the least surprised at finding nearly all the principal roots had penetrated the drainage and reached the subsoil, which was undoubtedly the cause of the Grapes shanking, &c. These bare thongs we followed as far as we could, severed them, and tied them to the stems, damped them well, and covered them with wet mats. I need hardly say that while this was going on the Vines were very heavily shaded. I then had the drainage put right and the border refilled with a compost of moderately heavy loam, half-inch bones, and lime rubble, to within 8 inches of the top. I made a close inspection of the roots and cut off all that were damaged, some of which measure 3 feet or more in length, and as free of rootlets as a walking stick. On these I made incisions right and left at intervals of 6 to 10 inches, carefully relaid them and covered them with the new compost. It was somewhat doubtful whether or not the following season these Vines would prove a failure, especially considering the few roots we found attached to each Vine. As soon as the planting was finished the whole of the border received a thorough supply of tepid water. The house was kept close for several days, and the Vines syringed several times daily. They soon began to show signs of renewed vigour, and several of the young laterals which had been encouraged before lifting the roots quickly rambléd over the trellis, and we then gradually admitted air and reduced the shading. I found on examining the border after the leaves had fallen from the Vines, which was about the usual time, that several young roots had already pushed into the fresh soil, some of which was almost as thick as quills. I allowed the following year each Vine to make a fresh rod to encourage a plentiful root action, and they were in no way hurried into growth, with the results previously stated.—H. MARKHAM, *Mereworth Castle Gardens*.

THE SUMMER OF 1888 AND INSECT LIFE.

WHETHER the late Admiral Fitzroy was right in a prediction he is said to have made—viz., that 1888 would prove to be the last in a series of summers mostly unfavourable, can only be decided by time. This is certain, that if it be the last it was almost the worst of the bad seasons we have had for twenty years past, and there have been many. The rainfall was excessive, especially through July, as Mr. Symons has shown in his "Meteorological Magazine," though not unprecedented, but the low maximum temperatures have been very exceptional, and it is to the coldness even more than to the moisture that our loss and damage in field or garden is to be ascribed. The two, however, are closely connected, the cold being the direct consequence of the heavy rainfall, the reason of which is not apparent. This is to be considered, that in many places throughout Britain the spring was, on the whole, a dry one. We have not positive data as yet, but I am inclined to hope it will appear that the injury sustained will turn out to be less than some anticipated; and there are a number of localities, both coast and inland, where the reports as to the average weather of this summer contrast markedly with the general aspect, but the London district, be the reason what it may, is one that has had a bad time of it, hence the lugubrious tone of the leading journals.

The observation of gardeners throughout the country will bear me out in the statement that those insects which are commonly troublesome in the months of July, August, and September have been less abundant than usual in consequence of the frequent rains and the lack of warmth. It may be accepted as a fact that ungenial summers like that we have just endured do tend to reduce our insect enemies; but we must, I think, at once discredit a still

prevalent notion amongst country folks that thunderstorms destroy a good many insects, for 1888 has been a year of thunderstorms and thunder showers; still, I cannot trace a diminution of insects to any electrical disturbances this year any more than in former years. If insects are killed in storms it is not by the lightning, but by the frequently heavy rain accompanying. What, then, occasions the death of insects or the suppression of broods which might have hatched out in such seasons as 1888? There is a double influence, upon the food of insects and upon the insects themselves, and we may take just two instances of the former as an illustration. Some insects in their larval stage feed upon the flowers of wild or cultivated plants. One peculiarity of this season has been that with many species the weather tended to encourage a profuse growth of leaves, but checked the development of blossoms, thus subjecting the flower-eaters to short commons, possibly even to starvation, where the envelopes have been washed off by rains. Then, again, with certain root-feeders; some roots have this year in consequence of the moisture been so decomposed that other species have come into rivalry, and the caterpillars or grubs which subsist upon healthy roots have been ousted by others which live upon them when decaying.

But it is rather upon the insects themselves that the influence of a wet and cold season are perceptible. In the egg state they sustain no injury, yet it may happen that the emergence of the young larvæ is so far delayed as to render it less easy for them in hatching to obtain their appropriate food. Thus I have noticed a Lilac-eating caterpillar of the Tortrix family come out late some seasons, and in consequence many were starved from the shrub losing its leaves suddenly and rapidly. Still, to a great extent plants and insects keep pace together, a check to one proving also a check to the other. It is in the larval or second stage of life that the effects of an ungenial summer tell chiefly on insects. Beetle grubs suffer little; those of butterflies and moths are very susceptible, dying off from diarrhoea or a fungoid disease; also in the order to which the plantlice and scale insects belong, it is noticeable that nearly all the species thrive best during warm and dry, but not excessively dry, weather. The pseudo-caterpillars of the saw-fly group, however, seem to flourish in showery weather. Insects of all orders while in the pupa or quiescent state, should they be in the earth, are likely to be killed when the soil is super-saturated with moisture and they are more exposed to the attacks of bird or molluscosous foes. Cocoons of insects fastened to twigs or walls are frequently damaged by the high winds of summer, and the contents fall out to be eaten by other creatures. Lastly, in their final stage of life, during wet summers, multitudes of insects with tender wings and bodies are, even if they survive for a while, unable to accomplish the work of depositing eggs to produce a future brood. I venture to think we may not be much troubled with insects next year.—ENTOMOLOGIST.

POTATOES.

THE present is a busy time with farmers and gardeners in lifting and storing Potatoes, and a few notes may not be out of place. In a season like the present great care should be exercised in lifting and storing the tubers so as to preserve them in the best condition until they are wanted for use. I remember when I was a lad my father used to grow some excellent crops of Potatoes, and his plan was always to get them up as soon as ripe, and in as dry a state as possible, and then store them in pits on the ground, covering them with thin turves or straw, and about a foot in depth of earth, making the pit smooth and even with the back of the spade to throw the rain off.

Since those days I have helped to lift and store Potatoes in different parts of the country, and have seen it done in various ways, but still I think where several tons of Potatoes have to be stored away for use through winter and spring no plan with which I am acquainted is better than the one I have just mentioned. Where good cool sheds exist and plenty of room, and where the frosts can be kept out, then I should by all means use them, taking care to have the tubers always well covered up in frosty weather.

Where they are stored in pits out of doors, and when wanted for use the pit should be opened on a fine day, and enough taken into a shed or some handy place to last a fortnight or longer. Sometimes in a long spell of frosty weather it will necessitate breaking into the pit to obtain Potatoes for present use. In this case I would open it in the middle of the day, have the tubers taken in as quickly as possible, and the pit closed again without delay. I have seen this done in very severe weather with no bad effects resulting.

In cases where the tubers are affected with disease they should be well sorted, and no tubers that are in the least diseased should

be placed with the sound ones, but should be stored by themselves for immediate use. If stored with the others they will soon do much damage, and the whole may become diseased.

All Potatoes should now be lifted without delay when the ground is in good order and the tubers come out clean, which enables it to be seen which are diseased and which are not. Out of seven early and second early sorts grown here Myatt's Ashleaf and Veitch's Improved Ashleaf have been the worst diseased. Beauty of Hebron showed signs of the malady first, but the haulms were at once pulled up, and when lifted about three weeks after scarcely a diseased tuber was to be seen. Main Crop Kidney has turned out well with us; only two or three diseased Potatoes could be found. The tubers are of even size, and when cooked are very good. Sutton's Abundance and Adirondack are two first-class main crop Potatoes that I can strongly recommend. They are heavy croppers and are not much affected with disease, are of excellent flavour when cooked, and keep well to May and June—G. HILTON.

GROS MAROC AND COOPER'S LATE GRAPES.

MORE than once the distinctness of the above varieties has been questioned in this Journal, and having two canes of each variety planted side by side about two years ago they were fruited this year for the first time, and I have paid them particular attention from the time that the Vines started growing until now, when the crop is ripe, and I consider them quite distinct varieties. Their growth and foliage are alike, except that Gros Maroc is a little darker in the foliage before coming into flower, but in this early stage of growth the most marked difference is at the thinning stage. The bunches of Cooper's Late when ready to thin is very like a Black Hamburgh, the berries all drooping down with long footstalks, whereas the bunches of Gros Maroc are more like Gros Colman, with berries quite stiff and horizontal. Passing to their present stage we have the two varieties ripe covered with a fine bloom, but if anything Gros Maroc is the better in this respect, but in shape of bunch and size of berry they show quite a distinct character. The bunches of Cooper's Late are longer and more tapering than Gros Maroc, with smaller and rounder berries. The following will clearly explain. All the bunches of the two varieties were thinned alike, and I now find that Gros Maroc was left too thick, as some of the berries are quite jammed, while the bunches of Cooper's Late are rather loose, and a few more berries left at thinning would be an improvement. I may say that I secured the eyes of Cooper's Late from Mr. Lees when gardener at Hillsborough Castle, and who used to show it so well at the Edinburgh autumn shows.—DAVID MURRAY, *Culzean Castle, Maybole.*

BERKELEY CASTLE.

THERE are few of the "historic homes of England" to which a deeper interest, and none to which a more tragic one attaches itself, than that which surrounds the ancient homes of the Fitzhardinges, for it was here that the weak and unhappy King Edward II. was "done to death," after suffering a series of prolonged humiliations and miseries, which covered his enemies with shame, and has left their name to be abhorred by all succeeding generations of Englishmen. It had long been my desire to visit this fine old baronial castle, and an opportunity having presented itself during a late visit to Gloucestershire, I gladly availed myself of it. To visit a place is one thing, but to visit it in pleasant company is another, and as a curious incident in one's life, I may be pardoned if I allude to it. Forty-nine years ago a very merry party went over in a yacht to see that magnificent pageant the Eglinton Tournament. We were thirteen in number, most of us young. Of all the number all had passed away except two, and those two had never met since then until the Gloucester Rose Show, when a lady found me out there and made herself known to me. At first I failed to remember, but when she mentioned the Eglinton Tournament all came back fresh to my memory. At her request I visited her at her husband's pleasant vicarage near Gloucester, and he very kindly arranged the party which on a bright and pleasant day—of which we have had so few this year—we made to Berkeley Castle. How much changed from those early days all was! and yet I am thankful to say we did most heartily enjoy ourselves, and were able to be thankful that after so many many years we were permitted to meet again.

I have said that much mournful interest attaches to Berkeley Castle, and, like most of our ancient castles, it has a long and interesting history; and, as is so often the case, totally different families, but assuming the same name, were successively owners of the estate. The De Berkeleys who originally held it were of an old Saxon family, who took their name from the manor of which they became possessed, and lived there until the male line became extinct in the reign of Stephen in 1182. In the wars of Stephen's reign the Empress Matilda received money and assistance from the Bristol merchants, amongst whom was a Robert Harding or Fitz Harding; for this assistance he was rewarded by the gift from Prince Henry of the Manor of Berkeley, expelling

therefrom Roger de Berkeley. However matters were smoothed over by what was often an expedient in those days—a marriage—and thus Robert Fitzhardinge obtained quiet possession of the Royal manor of Berkeley, and in his family it has remained with one short exception up to the present time. The lords of Berkeley have played no unimportant part in English history. One of them was amongst the Barons who won Magna Charta from King John, and the Castle was one of their meeting places. They were engaged in the war which reduced Wales, and also in the Scotch wars against Wallace and Bruce. They crossed the sea and fought at Crecy, Poitiers, and Agincourt. The meeting between Henry of Lancaster and the Duke of York, which led to the downfall of Richard II., was held at the Castle. They took no active part in the wars of the Roses, having a nice little quarrel of their own to settle, during which the Castle was taken and retaken several times. Berkeley suffered during the Parliamentary wars, but less so than many places; while in recent years the lords of Berkeley have been remarkable for their love of sport, and a fine pack of hounds testifies to the present earl's love and encouragement of sport.

The garden at Berkeley Castle is not what is called a show garden. You see no such stately houses as at Chatsworth, nor the long range of structures as at Drumlanrig, nor the grand gardens of Trentham. In these and other places the individual taste of the owner favours the operations of the gardener. But Lord Fitzhardinge has no love for flowers. If he walks through the gardens he takes but little interest in them, and hence they are more utilitarian than ornamental. Plants are grown in them, and grown well, by Mr. Shore, who unfortunately was absent at the time of my visit; but they were plants mostly used for the ornamentation of the house, whether as plants or cut flowers. Nowhere have I seen better plants of *Eucbaris grandiflora* all in good and healthy condition. Here, too, one found well-grown examples of a fine stove plant, too often neglected, but wherever grown always welcomed, *Strelitzia reginae*, while the small conservatory was gay with *Begonias*, *Pelargoniums*, and well-managed plants of *Campanula pyramidalis*, which is exceedingly effective when well done at this time of the year. Then the houses devoted to fruit were in excellent order; a fine crop of Peaches and Grapes had been gathered, and others were in course of coming on, and so all through everything was well done.

But I think the chief feature at Berkeley is the terrace garden. This is situated at the south side of the Castle and against its walls. It is thus in a sunny and favourable aspect for growing many things, especially in the sheltered position that Berkeley occupies. Against the walls *Magnolias*, *Roses*, *Ceanothus*, *Myrtles*, and other flowering shrubs occupy places which were doubtless in former times filled with various means of defence, which it became needful to use, exposed as it was to the incursions of the Welsh. On the terrace itself are beds of various flowers, such as *Salpiglossis*, *Carnations*, and other old-fashioned flowers, the sunny aspect of the terrace being peculiarly adapted for their early development. Then in another part is the neatly kept bowling green, surrounded by shrubs of various kinds, and then what grand trees and what abundant foliage there is about the place! how splendid are the Elms, which rejoice in their rich deep soil! and what a grand view is obtained from these terraces, or better still from the tower called Thorpes Tower! Here the eye may roam over a view unsurpassed in its way for loveliness and beauty. North and south runs the rich vale of Berkeley, with its verdant pasture and splendid foliage. Turning to the east and south-east the Cotswolds are seen rising up here and there through the dense mass of Beech groves which clothe their sides into the bare chalky downs in which their summits end, and then you see deeply wooded valleys running into them, where doubtless many a scene of beauty can be enjoyed. On the west side the Severn flows, while beyond it are the woods of the Forest of Dean, suggestive of much coal and iron, of collieries and smelting works, while close at hand the town lies, as in so many cases of these old castles, nestling for shelter, and as in Arundel, Alnwick, and other places, and, indeed, as it was needful, for as the inhabitants were all in some way connected with the Castle, they needed to be protected when the lords of Berkeley had to defend themselves.

Before concluding this brief notice of Berkeley Castle, let me say that although the gardening presents no grand features it does present that which is often wanting in more pretentious places, extreme neatness and tidiness. Nowhere inside the houses or out of doors were there the slightest marks of slovenliness. I have been to places from whence the most magnificent plants were sent to the chief shows in the kingdom, and one had to go through a series of dung heaps to see them, and except in the houses themselves dirt and confusion ruled supreme. Here both garden and pleasure ground were pleasant to see, and did much credit to Mr. Shore, under whose management they have been for some years.—D., *Deal.*

A USEFUL PEACH CASE.

PEACH-GROWING, as most gardeners know, is very uncertain out on the open walls, and the genial rector of Welbourn, the Rev. F. Leslie Melville, and his family, who are fond of good Peaches, found trusting to trees on a south wall was very disappointing. An elaborate Peach house heated with hot water was not wanted, but sufficient shelter to protect the trees when in bloom; also something that would help to ripen the fruit and wood for the following year. That this has been accomplished may be judged from the fact that trees are loaded with fruits. I counted seventy-eight beautiful fruit on one tree of Grosse Mignonne Peach, 9 feet 6 inches by 7 feet, and several others were cropped in the same way. The trees are well supplied with liquid

manure, but I do not think they can carry crops like they have this season many years without a breakdown. Noblesse and Royal George were well cropped, also Princess of Wales, but was not thought highly of, it had no colour scarcely. Nectarines were as heavily cropped as the Peaches. Strange to say there was a large Green Gage Plum on the wall about the middle of the case. Not one fruit had there been on it this year. I was told there was a good crop last year; the tree promises well for 1889. I may say that the Rev. F. Leslie Melville will be pleased to show his Peach case to anyone interested in Peach-growing without fire heat. Welbourn is about halfway between Grantham and Lincoln, by the side of the Great Northern Railway. Leadenham is the station for Welbourn.

I will give the size of the Peach case as nearly as possible: Length, 98 feet; height of back wall, 8 feet; width at ground line, 7 feet. Two 11-inch boards form the front or perpendicular, one board is hinged and forms the front ventilator. The top glass just slopes enough to allow the water to run off. The top is 3 feet 6 inches wide; the front glass is 6 feet from the angle at roof to front boards, and slopes into the place 3 feet. There is a 6 or 7-inch board hinged and worked with iron rods for top ventilation. The glass is 21 ounce, 20 by 15 inches, the bars for glazing are T irons 15 inches apart. A board 11 inches wide and 1 inch thick is placed flat side to the wall at the top. Just under the eave bolts go through the board and wall and screw up tight. The T irons are screwed to the top side of the board. There are about 7 inches of glass left out of the T irons; the 7-inch board is hinged to the same board, I believe for ventilation. To strengthen the front there is $\frac{3}{4}$ -inch iron rod let into a stone in the ground every 4 feet. There is a T iron runs along the bottom of the others; they are rivetted to the one horizontal, and the bolts or rods through it also, and all rivetted together. I was told the whole of the 98 feet run, and 8 feet high and 7 feet wide at the base, cost about £20.—GEO. PICKER.

THE PROGRESS OF BOTANY.

(Continued from page 297).

GEOGRAPHICAL BOTANY.

A GOOD deal, however, has been done. We owe to the indomitable industry of Mr. Benthams and of Sir Ferdinand Mueller a comprehensive flora of Australia, the first large area of the earth's surface of which the vegetation has been completely worked out. Sir Joseph Hooker, in his retirement, has pushed on within sight of completion the enormous work of describing so much of the vast Indo-Malayan flora as is comprised within the British possessions. To the Dutch botanists we owe a tolerably complete account of the Malayan flora proper. But New Guinea still remains botanically a *terra incognita*, and till within the last year or two the flora of China has been an absolute blank to us. A Committee of the British Association (whose report will be presented to you) has, with the aid of a small grant of money, taken in hand the task of gathering up the scanty data which are available in herbaria and elsewhere. This has stimulated European residents in China to collect more material, and the fine collections which are now being rapidly poured in upon us will, if they do not overwhelm us by their very magnitude, go a long way in supplying data for a tentative discussion of the relations of the Chinese flora to that of the rest of Asia. I do not doubt that this will in turn explain a good deal that is anomalous in the distribution of plants in India. The work of the Committee has been practically limited to Central and Eastern China. From the west, in Yunnan, the French botanists have received even more surprising collections, and these supplement our own work in the most fortunate manner. I have only to add, for Asia, Boissier's "Flora Orientalis," which practically includes the Mediterranean basin. But I must not omit the invaluable report of Brigade-Surgeon Aitchison on the collections made by him during the Afghan Delimitation Expedition. This has given an important insight into the vegetation of a region which has never previously been adequately examined. Nor must I forget the recent publication of the masterly report by Prof. Bayley Baifour on the plants collected by himself and Schweinfurth in Socotra, an island with which the ancient Egyptians traded, but the singularly anomalous flora of which was almost wholly unknown up to our time.

The flora of Africa has been at present but imperfectly worked up, but the materials have been so far discussed as to afford a tolerably correct theory of its relations. The harvest from Mr. Johnston's expedition to Kilimanjaro was not so rich as might have been hoped. Still, it was sufficient to confirm the conclusions at which Sir Joseph Hooker had arrived, on very slender data, as to the relations of the high-level vegetation of Africa generally. The flora of Madagascar is perhaps, at the moment, the most interesting problem which Africa presents to the botanist. As the rich collections, for which we are indebted to Mr. Baron and others, are gradually worked out, it can hardly be doubted that it will be necessary to modify in some respects the views which are generally received as to the relation of the island to the African continent. My colleague, Mr. Baker, communicated to the

York meeting of the Association the results which, up to that time, he had arrived at, and these subsequent material has not led him to modify. The flora as a whole presents a large proportion of endemic genera and species, pointing to isolation from a very ancient date. The tropical element is, however, closely allied to that of Tropical Africa and of the Mascarene Islands, and there is a small infusion of Asiatic types which do not extend to Africa. The high-level flora, on the other hand, exhibits an even closer affinity with that temperate flora, the ruins of which are scattered over the mountainous regions of Central Africa, and which survives in its greatest concentration at the Cape.

The American botanists at Harvard are still systematically carrying on the work of Torrey and Gray in the elaboration of the flora of Northern America. The Russians are, on their part, continually adding to our knowledge of the flora of Northern and Central Asia. The whole flora of the North Temperate Zone can only be regarded substantially as one. The identity diminishes southwards and increases in the case of the Arctic and Alpine regions. A collection of plants brought us from high-levels in Corea by Mr. James might, as regards a large proportion of the species, have been gathered on one of our own Scotch hills.

We owe to the munificence of two English men of science the organisation of an extensive examination of the flora and fauna of Central America and the publication of the results. The work, when completed, can hardly be less expensive than that of the results of the *Challenger* voyage, which has severely taxed the liberality of the English Government. The problems which geographical distribution in this region presents will doubtless be found to be of a singularly complicated nature, and it is impossible to over-estimate the debt of gratitude which biologists of all countries must owe to Messrs. Godman and Salvin when their arduous undertaking is completed. I am happy to say that the botanical portion, which has been elaborated at Kew, is all but finished.

In South America, I must content myself with referring to the great "Flora Brasiliensis," commenced by Martius half a century ago, and still slowly progressing under the editorship of Prof. Urban, at Berlin. Little discussion has yet been attempted of the mass of material which is enshrined in the mighty array of volumes already published. But the travels of Mr. Ball in South America have led him to the detection of some very interesting problems. The enormous pluvial denudation of the ancient portions of the continent has led to the gradual blending of the flora of different levels with sufficient slowness to permit of adaptive changes in the process. The tropical flora of Brazil, therefore, presents an admixture of modified temperate types which gives to the whole a peculiar character not met with to the same degree in the tropics of the Old World. On the other hand, the comparatively recent elevation of the southern portion of the continent accounts, in Mr. Ball's eyes, for the singular poverty of its flora, which we may regard indeed as still in progress of development.

The botany of the *Challenger* Expedition, which was also elaborated at Kew, brought for the first time into one view all the available facts as to the floras of the older oceanic islands. To this was added a discussion of the origin of the more recent floras of the islands of the Western Pacific, based upon material carefully collected by Prof. Moseley, and supplemented by the notes and specimens accumulated with much judgment by Dr. Guppy. For the first time we were enabled to get some idea how a tropical island was furnished with plants and to discriminate the littoral element due to the action of oceanic currents from the interior forest almost wholly due to frugivorous birds. The recent examination of Christmas Island by the English Admiralty has shown the process of island flora-making in another stage. The plants collected by Mr. Lister prove, as might be expected, to be closely allied to those of Java. But the effect of isolation has begun to tell; and I learn from my colleague, Prof. Oliver, that the plants from Christmas Island cannot be for the most part exactly matched with their congeners from Java but yet do not differ sufficiently to be specifically distinguished. We have here, therefore, it appears to me, a manifest case of nascent species.

CLASSIFICATION.

The central problem of systematic botany I have not as yet touched upon: this is to perfect a natural classification. Such a classification, to be perfect, must be the ultimate generalisation of every scrap of knowledge which we can bring to bear upon the study of plant affinity. In the higher plants experience has shown that we can obtain results which are sufficiently accurate for the present without carrying our structural analysis very far. Yet even here, the correct relations of the Gymnosperms would never have been ascertained without patient and minute microscopic study of the reproductive processes. Upon these, indeed, the correct classification of the Vascular Cryptogams wholly depends, and generally, as we descend in the scale, external morphology

becomes more and more insecure as a guide, and a thorough knowledge of the minute structure and life-history of each organism becomes indispensable to anything like a correct determination of its taxonomic position. The marvellous theory of the true nature of Lichens would never have been ascertained by the ordinary methods of examination which were held to be sufficient by lichenologists.

The final form of every natural classification—for I have no doubt that the general principles I have laid down are equally true in the field of zoology—must be to approximate to the order of descent. For the theory of descent became an irresistible induction as soon as the idea of a natural classification had been firmly grasped.

In regard to flowering plants we owe, as I have said, the first step in a natural classification to our own great naturalist, John Ray, who divided them into Monocotyledons and Dicotyledons. The celebrated classification of Linnæus was avowedly purely artificial. It was a temporary expedient, the provisional character of which no one realised more thoroughly than himself. He, in fact, himself gave us one of the earliest outlines of a truly natural system. Such a system is based on affinity, and we know of no other explanation of affinity than that which is implied in the word—namely, common parentage. No one finds any difficulty in admitting that, where a number of individual organisms closely resemble one another, they must have been derived from the same stock. I allow that, in cases where external form is widely different, the conclusion to one who is not a naturalist is by no means so obvious. But in such cases it rests on the profound and constant resemblance of internal points of structure. Anyone who studies the matter with a perfectly open mind finds it impossible to draw a line. If genetic relationship or heredity is admitted to be the explanation of affinity in the most obvious case, the stages are imperceptible by which the same conclusion is seen to be inevitable when the evidence is fairly examined, even in cases where at the first glance it seems least likely.

(To be continued.)

ONCIDIUM ORNITHORHYNCHUM.

THE above is a most useful species, blooming at a season when Orchid flowers are scarce. It is remarkably well grown by Mr. T. A. Glover, gardener to E. Ellis, Esq., Manor House, Wallington. One plant I noticed suspended in the conservatory, where it has been for several weeks, was in a 5-inch pot, carrying fifteen graceful drooping spikes, with a total of 650 beautifully scented and delicate rose-coloured flowers. It is grown in the Cattleya house near the glass. The pretty little *O. cheiroporum* under the same treatment is at the present time well furnished with branching spikes, and there will soon be a display of *O. varicosum* and *O. Rogersi* to succeed the *O. tigrinum*, *O. cucullatum*, which are now in flower. *Saccolabium guttatum* is here represented by a good form bearing a spike 18 inches long, densely clothed with white and purple blooms. *Cattleya velutina* and various *Cypripediums* are also flowering well.

Mr. Glover has succeeded in establishing a fine piece of the new *Coelogyne Sanderiana*, the fresh growths being nearly equal to the imported ones. It is grown on a shelf in a warm and moist house where *Phalaenopsis* used to do so well, in company with some fine *Calanthes*.—G. W. C.

ONCIDIUM JONESIANUM.

WHAT a very free-flowering Orchid this is! We have several plants now flowering beautifully, and they are most valuable for cutting from, as the spikes have a very elegant appearance. It succeeds in the Cattleya house in a basket with crocks, no peat or sphagnum being necessary. It needs a plentiful supply of water. The foliage is also very distinct from other *Oncidium*s.—A. Y.

COMPARETTIAS.

THERE are now numbers of beautiful winter-flowering Orchids in cultivation, and with a moderately extensive collection little difficulty is experienced in maintaining a bright and satisfactory display in the structures devoted to such plants. The small genus now under notice is well known to many Orchid growers; and though the few species it includes are not entitled to rank among the most showy of their order, they possess several recommenda-

tions. The racemes are elegant, generally drooping, and bearing small but brightly coloured flowers that are produced in the latter months of the year, or from January to March. The plants are all epiphytal in habit, succeeding well on small blocks of wood suspended from the roof of a moderately warm house, but not where they are too fully exposed to the sun. In other respects the treatment they require is similar to that of most tropical epiphytal Orchids.

Comparettia falcata, the species represented in fig. 34, is one of the best known, and is seen in most metropolitan nurseries and in the chief collections of Orchids in the country. It produces a rather loose raceme of deep rose or crimson-coloured flowers from the base of the pseudo-bulbs, the scape usually being much longer than is shown in the cut, the flowers being borne near the extremity. The labellum is the chief distinctive feature of the flower, it being strangely restricted in the middle. *C. rosea* is another pretty species with shorter and more compact racemes

FIG. 34—COMPARETTIA FALCATA.

than that mentioned above, but it is much more rarely seen. *C. coccinea*, which has pale scarlet tinted flowers, is very attractive and free in flowering, particularly handsome specimens being occasionally met with.—R. L.

MILTONIA CUNEATA.

THE *Miltonias* constitute a genus of handsome Orchids. The name was given in honour of Earl Fitzwilliam, who was an ardent admirer of plants of this nature. They are mostly natives of Brazil, and consequently require a warm stove temperature, especially during the season of growth. If given heat and a moist atmosphere few Orchids grow more freely or flower more profusely, and their richly coloured flowers are admirable for cutting and the furnishing of vases, &c. The plants will grow either in baskets or in pots; if in the latter it is necessary that they be potted very high—that is, the pots should be nearly filled with crocks; and the material, very fibrous peat, sphagnum, and charcoal, should be made to form a cone above the rim of the pot. The creeping stems from which the pseudo-bulbs grow should be pegged to the surface of the compost with small hooked pegs, and with good cultivation the plants will increase in size rapidly. If grown in baskets the plants re-

quire much the same treatment as Stanhopeas as to heat, moisture, and rest. The species vary considerably in size and colour of their flowers, but all are attractive and worthy of culture. *M. spectabilis* is white and violet, and is, as its name implies, very showy, as also are its darker varieties *autropurpurea* and *colorata*. *M. candida* has a white lip and yellow and brown sepals, while *M. cuneata*, the wedge-lipped *Miltonia*, is yellow and purple. The plants being epiphytal grow perhaps best in baskets, and will flourish in any plant stove where the summer temperature ranges from 60° to 90°, and the winter temperature from 55° to 60°.—B.

THE CULTURE OF PHAIUS.

THIS fine genus of Orchids are all terrestrial—that is, they are found in their native habitats growing on the ground. It follows that a plant found growing on the ground requires, in artificial culture, a soil approximating to that from which it has been brought. The soil in woody dells in the Mauritius, China, Nepal, and other places where they are found is generally of a loamy texture, but the surface is composed of the *débris* of the trees of the forest for generations, consisting chiefly of leaves, twigs, and branches in a decaying state. In order to imitate such a soil we have used always for these plants a compost of loam and leaf mould, not too much decayed, and sand sufficient to keep it open, with perfect success.

Drainage is a point of considerable importance in their culture, as on account of their rapid large growth they require generally large pots; the drainage should be in proportion. Cover the hole or holes at the bottom of each pot with one large piece of broken potsherd or an oyster shell; prop this up with a small piece of pot thick enough to allow a free passage for the superfluous water; then place over them a layer 1 inch thick of smaller broken potsherds, and over them a layer half an inch thick of the smallest size without any dust amongst them (this should be sifted out with a very fine-meshed sieve, and will be useful to mix with the compost for dry stove or succulent plants). Cover these finally with some bog moss not too thick, and then the drainage will be perfect.

POTTING.—The season for this operation depends upon the state of the plants. If properly managed with regard to the season of rest they should begin to grow about the middle of February, and then is the time to set about potting. Take the plant or plants to the potting bench, turn the pot upside down, catch the ball with one hand, and remove the pot with the other. Give the ball a gentle tap on the edge of the bench to loosen the soil from amongst the roots, and then dress the plant all over; trim off all dead or decaying roots, cleanse the pseudo-bulbs from old sheaths, insects, &c.; dead or decaying leaves cut off at once, and sponge the fresh living ones with tepid water, cleaning off and destroying scale, bug, or any other vermin infesting them. If it is desired that is the time to divide the plants for increase. One or more of the back or oldest pseudo-bulbs may be cut off just at the connecting joint; these should be potted into small pots, and have no water till fresh shoots are made. Should very large specimens be desired these divisions may all be put in the same pot together and allowed to grow together till they flower, and thus form one large fine specimen. To return to potting. After the plant is well cleansed and divested of all dead and decaying matters proceed to pot it. First put in the new pot a slight layer of earth upon the drainage, then work in the long wiry roots equally all round and in the pot, then hold the plant in the centre of one pot with one hand and gradually mix the earth amongst the roots with the other. This will take a little time and care to do it well without injuring the roots or thrusting them together in bundles—the endeavour and aim should be to leave the roots equally spread out amongst the new soil. Finish by leaving the plants level with the rim of the pot, press down the soil at the sides next the rim to hold a fair supply of water, and the operation is finished.

The best position is a mildly heated bed of tanner's bark, either in a pit or in a common Pine stove. The nearer they are to the glass, so as not actually to touch it, the better. They should be well shaded with a canvas shade that will shelter them from the rays of the sun in summer, but remove it in winter; the leaves are thin and are easily disfigured if exposed during summer to its rays. Give air moderately on all fine days, but not too much at once.

Excepting *Phaius grandifolius* they all require a high temperature when growing, 75° to 85° by day and 65° to 70° by night. In winter the heat should be very moderate, because then the plants are at rest.

WATER.—If the plants are plunged in a bark bed, they will not require so much water as they would if grown on a platform over the pipes or on a stage in the centre of the house. Water, then, according to the position the plants occupy, only take notice that too much water at any time is highly injurious, and will cause the roots to perish very suddenly. In the resting season scarcely any

water will be required, only enough to keep the leaves from flagging too much. Some lose their leaves entirely once a year; such will bear scarcely any water when at rest. The syringe may be used freely when the plants are growing. Allow the water to fall upon the leaves like a gentle Scotch mist or drizzling rain; but when using it to the under side of the leaves give a little more force to wash off the red spider, should he have founded a colony there.

As the flowers of the greater part of the genus appear at the same time as the new growths it follows that they will flower in the early part of the year, generally about the end of April to the beginning of June. *Phaius grandifolius* may be so managed by starting it into growth at various periods as to greatly prolong the season of its blooming. We have had it in flower from January to June by starting a plant or two at a time at intervals of a month between each period.

Like their epiphytal compeers the terrestrial Orchid must have a season of rest; and as light is necessary to grow and mature the growth, it follows that the best season for repose is when there is the least amount of light in our climate; therefore, the winter months are the best for placing these plants to rest.—ORCHID GROWER.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

ON September 8th last at the conclusion of the Conference of fruit growers in the Crystal Palace, Mr. J. Cheal proposed a resolution to the following effect—namely, "That it is desirable an Association of fruit growers should be formed for the promotion of profitable fruit cultivation, and to improve the methods of distribution. The Executive Committee of the Conference being requested to prepare a report on the subject, to be submitted to the next meeting at the Crystal Palace, on October 11th this year." In pursuance of this resolution the Executive Committee met at 5 P.M. on Thursday, September 27th, at Anderton's Hotel, Fleet Street, T. Francis Rivers, Esq., in the chair, twelve members being present. The Chairman referred to the favourable notices accorded by the daily and horticultural press to the Conference at the Crystal Palace, and it was mentioned that over sixty reports and articles referring to it had been published. A draft of the Association was then read, considered at some length, and finally adopted.

The adjourned Conference will be resumed at 2 P.M. on Thursday, October 11th, at the Crystal Palace.

The following is the draft adopted at the above meeting, and all desirous of joining the Association should communicate with the Hon. Secretaries, Mr. Lewis Castle, Hotham House, Merton, Surrey, or Mr. William Earley, Ilford, Essex.

The title will be, "The British Fruit Growers' Association."

OBJECTS.

To promote the profitable culture and the improvement of fruit in the United Kingdom, and to facilitate the distribution to consumers.

METHODS.

It is proposed to effect these objects by the means of meetings and conferences in the metropolis and the provinces; the collection from all districts of reliable information bearing on the subjects, its dissemination through the daily and horticultural press; by the publication of annual reports with such others of a special character as the funds of the Association may permit; and by securing the adherence of local societies to the object of the Association.

MEMBERSHIP.

A subscription of not less than 5s. annually shall entitle any person duly elected to membership of the Association, including admission to all conferences and general meetings, one copy of each publication issued by the Association, and such farther privileges as may be subsequently determined. First subscriptions to be paid at the date of joining, and subsequently annually on January 1st.

OFFICERS.

The officers of the Association shall comprise a President, Vice-Presidents, a Treasurer, and two Honorary Secretaries.

COMMITTEES.

The business of the Association shall be conducted by the officers, a General Committee of forty members, an Executive Committee of fifteen members, five to form a quorum, and special Sub-Committees to be elected by the latter, the officers being *ex-officio* members of all Committees.

ELECTION OF MEMBERS, OFFICERS, AND COMMITTEES.

Proposed members of the Association to be nominated by two members and elected at any meeting.

The officers to be elected annually.

Ten members of the General Committee to retire annually, but to be eligible for re-election; the retiring members in the first two years to be decided by ballot, and subsequently in the order of election. Nominees for the Committee to be proposed and seconded by two members of the Association at the annual general meeting. All elections to be effected by open voting.

The Executive Committee to be elected by the General Committee

from amongst themselves after the general business at the annual meeting.

MEETINGS.

The annual general meeting shall be held in December of each year to receive the report of the General Committee, for the election of officers, Committees, and the transaction of any other important business.

The General Committee shall hold at least two meetings, and the Executive Committee shall meet as often as necessary, in each year. The Executive Committee to decide the dates and places for all meetings and conferences.

NEW ROSES.

Of the new Roses sent out this and last year I have grown the following in sufficient quantities, and with sufficiently close daily observation, to offer the following remarks upon them, in case it may interest some of the readers of "our Journal."

Teas.—Château des Bergeries, Dr. Grill, Duchesse de Bragançe, Luciole, Madame A. Etienne, Madame Honore Defresne, Madame Scipion Cochet, Mdle. Elizabeth de Gramont, Princess Beatrice, Ye Primrose Dame, The Bride, Duchesse d'Auerstadt, Madame Hoste, Madame Joseph Godier, Mdle. Henriette de Bauvan, and Princess de Sagan.

Hybrid Teas.—Madame Joseph Desbois, Madame Carle, and Mdle. Germain Caillot.

Chateau de Bergeries.—Fairly vigorous in growth; the flower a pleasing, clear, palish yellow, but opens badly out of doors; with me not very satisfactory.

Dr. Grill.—A good healthy grower; flower very pleasing in calm, bright weather, well-formed, opens well, fairly large in size, and is a pleasing garden Rose of salmon rose colour.

Duchesse de Bragançe.—A moderately vigorous grower, free blooming, well formed, nearly globular flower of good medium size, clear Australian gold colour, rather paler on outer petals; under glass, say for March blooming, I have a good opinion of and value this Rose, then very pretty and an acquisition.

Luciole.—A most unique, æsthetic kind of Rose; most distinct flower; a mixture of carmine, rose, yellow and fawn; fairly vigorous grower and free blooming; best under glass, and will, I think, be a good forcer; bud long, flower double, petals rather weak.

Madame A. Etienne.—Fairly good grower and bloomer; flower fine, distinct form; colour clear, pale, rosy pink with whitish base of petals; not so good a Rose as I at one time expected.

Madame Honore Defresne.—A good vigorous grower; flower full and rather large; colour deep clear yellow; outer petals reddish; opens badly.

Madame Scipion Cochet.—I think this is perhaps the best open ground Tea of the French Roses of last year, good grower, fairly free bloomer; flower large, well formed, opens well; and reminds me something of Princess of Wales in form and colouring.

Mdle. Elizabeth de Gramont.—Seems a dwarf descendant of Gloire de Dijon, but quite different in colour, being bright reddish rose with yellow; good dwarf; healthy grower of stout wood and short joints.

Princess Beatrice.—A splendid Rose under glass, excellent for forcing; most lasting flower, and beautiful clear yellow, then good grower and healthy; not so good in the open with me.

Ye Primrose Dame.—Moderately vigorous grower, best under glass; pretty well formed flower; pale yellow in centre, nearly white outer petals.

The Bride.—The best and most beautiful Tea since Catherine Mermet, of which it is in every way a fac-simile, except in colour, which is a white with yellowish tinge; splendid.

Duchesse d'Auerstadt.—My plants of this have grown so strongly I have seen no flower shoots as thick as my little finger, and 6 feet long, chocolate red coloured shoots and leaves; a strong climber evidently.

Madame Hoste.—The best French Tea of this year in my opinion, and a decided acquisition; good healthy grower, flower deep petalled, large, and moderately full, opens well, blooms freely, colour whitish, with yellow at base of petals at times.

Madame Joseph Godier.—This is something like Dr. Grill, and not remarkable in any way, but a pleasing garden Rose.

Mdle. Henriette de Bauvan.—This seems to me as if it might be a seedling of Madame Eugène Verdier Tea, growth in shoots and flowers remind me strongly of that Rose. So far I cannot say I expect great things of this last Rose of Lacharme, but I hope it may turn out better than I now expect.

Princess de Sagan.—This Rose seems to me merely a crimson China, both in growth and flower. The colour is a rich deep shaded velvety crimson, but I have seen no flower larger or better than a flower of Eugène Beauharnais.

Madame Joseph Desbois and Mdle. Germain Caillot.—Very similar in the flower, which is very like that of Captain Christy. Rather uncertain growers I have found both of them; but the flowers are

beautiful, and I think both will appear on the exhibition table at times.

Madame Carle.—A distinct, moderately vigorous, short-jointed grower; flower almost like a Camellia, varying in colour from that of Cheshunt Hybrid to a much brighter colour and more velvety. The flower is only moderate in size, and it is only a garden Rose.

So far as a few plants only will enable me to form the beginning of an opinion, I am much pleased with Miss Ethel Brownlow, and think anyone may venture to add that Rose to their list.—S. S.

THE MANETTI STOCK.

MR. J. W. MURPHY in last week's Journal asks for an explanation of some paradox which he imagines to lie in my note of 20th inst. in our Journal. I stated that in my opinion, derived from my personal experience, the Manetti is worse than useless, for if most Roses cannot live without it, they will not live with it in many soils. The meaning of this is, if many Roses cannot make roots of their own and thrive on them, such will die soon on the Manetti in many soils.

I also stated, I even think some good Roses have gone out of cultivation chiefly through Manetti, and instanced Olivier Delhomme, and further stated Marie Baumann hates that stock. How often from many quarters do we hear of Marie Baumann as a poor "miffy" grower. Now, I say from experience, grow it on the Briar, and then decide. With me Olivier Delhomme, a splendid Rose, durable and healthy on the Briar, or even on own roots, is miffy and soon dies on Manetti. I named the above merely as instances.

Prophesying is not at all in my way, but it is well to note the tendency of things, and I certainly think this is to discard the Manetti for whole classes of Roses by many good Rose-growers. Compare the present with fifteen years ago in this respect.—S. S.

It is time Mr. Murphy learnt to take his part in an argument without throwing out insinuations against his opponents. His reference to my "fertile imagination" can only bear one translation.

Mr. Murphy must know that insinuating that I draw on my "fertile imagination" for my facts will not make the Manetti the proper stock to grow Roses on, if it is not so already. Your correspondent mentioned my name in this matter in the first instance, or I should not have made any reply. In his remarks on page 287 he mixes me up sadly with another correspondent, and seems to expect me to answer for both. He gives a quotation, "Most Roses cannot live, except when budded on the Manetti," and asks me what I think of it. In reply, "I think it's a mistake."

Now Mr. Murphy says all the chief prizes won by nurserymen are won with Roses grown on the Manetti. Possibly this is so, but I do not see how this affects what has been said by me. Page 262: "It is notorious that Roses on the Manetti make a grand growth, and bloom well the first year with the nurseryman." Let us see what Mr. William Paul says: "That the plants grow more vigorously the first year we do not deny, but their subsequent decline is also more rapid."—(Page 156, 1881 edition, "The Rose Garden.") Let us see what Mr. B. R. Cant says: "The Briar cutting is my own especial pet."—"Rosarian's Year Book, 1888, page 20." The Rev. Mr. Pemberton says, "As cutbacks I do not like them . . . when pruned . . . they lose heart, and break very feebly."—"Rosarian's Year Book," 1888, page 22.)

Mr. Murphy says that many thousands of the Roses he saw at Newtownwards were old plants. I am afraid he is mistaken here; it does not pay nurserymen to keep Roses many years. I should like to know how many prize blooms are cut from over-year plants, not necessarily at Newtownwards, but in all the nurseries in the kingdom. If I made a guess I should say not one-thousandth part. They all, or nearly all, come from the maiden plants.

I should like Mr. Murphy to tell me how many Roses he has altogether in his collection; how many he has which are seven or eight years old; and how large, or rather how small, his blooms are.

The Manetti is most certainly unsuited to my soil. There is nothing like experience; and if anybody will plant side by side Roses on the Manetti, and the same on the Briar, I am content to await the result. Mr. Murphy asks, "Would the nurserymen combine to disappoint their customers?" &c. In reply to this, I say I see no signs of combining among the nurserymen, neither can I see any wrong in growing Roses on the Manetti. The public buys them with its eyes open, and according to Mr. Murphy prefers them.

Why Roses are grown on the Manetti:—

1, Because Manetti cuttings are easily made, and strike more certainly than Briars.

2, Because the sap runs earlier in the season, enabling budding to be commenced early, and continues running late, enabling budding to be extended far into autumn.

3, Because this stock is much easier to bud than the Briar, and takes more surely.

4, Because the Manetti makes splendid plants, and gives fine blooms the first year.

5, Because they can be sold cheaper than Briar plants, which suits the public.

The fact that Manetti Roses perish should not, in my opinion, be laid to the charge of the nurseryman. It is not his fault; he grows Roses on Manetti because his father did so before him, and he does not feel disposed to change. When the public demands Roses on the Briar, then the nurseryman will provide them.—D. GILMOUR, JUN.

A DISCUSSION has been raised in the columns of the Journal upon

the lasting qualities of Rose plants on the Manetti stock, and one staunch supporter of the foreigner in his vigorous onslaught upon "D. G." asks for the opinion of others upon the subject. Since we had but a few stocks yearly, just as many as my sister and I can manage between us—we have no Rose man—my experience is certainly a limited one, and it must be taken for what it is worth. We have tried the stock in question on many soils but a really good Rose soil, and whether on light land with a gravel subsoil or stiff yellow clay, it makes no difference, the Manetti is a failure as regards its lasting qualities. We have discarded it as a stock for the last two years, and are gradually getting rid of all cut-backs budded upon it. Perhaps it may find favour with some large growers for the following reasons:—1, Cuttings of it strike well; 2, It does not ripen as soon as the Briar, and so may be budded when these have ceased to run. Another advocate states that he has plants on Manetti "over twenty years old, and still vigorous and healthy." Then I should say they are really flourishing on their own roots, with the Manetti just existing but required no longer. This, at least, is how plants on Manetti serve us; and I do not like own-root Roses for exhibition purposes. The seedling Briar, perhaps, requires more care as a stock; but when budded it certainly with us produces finer and more lasting plants than any cutting stock, and I believe it to be the stock of the future. The foreigner must go home.—JOSEPH H. PEMBERTON.

It would be an interesting contribution to the Manetti controversy, on which there is much to be said on both sides, if someone would write to say he had lifted Manetti-worked Rose plants, not less than, say, five years old, on which no sucker had ever appeared, and found good living Manetti roots to them. I have never succeeded in such cases in positively identifying any of the live roots as belonging to the Manetti; and if, as some think, the Manetti invariably dies sooner or later if it cannot form a shoot of its own, there is no hope of sustained life for a Rose budded on it except in making roots for itself, which it generally succeeds in doing more or less. If this be true the flourishing old plants of Mr. Murphy and Mr. Russell are simply Roses on their own roots, and it seems to be doubtful if the Manetti can properly be called a stock at all in the usual acceptance of the term.

But Mr. D. Gilmour is probably mistaken in thinking it will therefore fall into disuse. It is easier and more certain in budding, and makes more wood the first year than any other stock, and these qualities alone render it a most desirable one to use for the propagation of new and valuable H.P. Roses. It is also early to grow and to bloom, and many H.P.'s do well on it the first year. "S. S." speaks of Marie Baumann disliking it. I cannot get this Rose to do well on any stock; it seems to be deteriorating, as it used to be considered the one Rose always good in any season. But the best twelve I ever saw of it, shown by Mr. B. R. Cant, were cut, his foreman told me, almost entirely from Manetti. Messrs. Harkness also use Manetti exclusively I believe for H.P.'s, and Mr. R. N. G. Baker, the present holder of the amateur champion challenge trophy, used to rely upon it very largely if he does not now. Lesser lights in the Rose world, like myself, may well consider these examples, but some will succeed where others fail.

I, though quite willing to be convinced, can do nothing with it, except in "manufacturing yearly Roses," which I find to be quite worth while in the case of some varieties; and I suppose it is no crime for an amateur to do this, especially if he gives the plants away in November, and honestly tells the recipients of his bounty that they will not grow.—W. R. RAILLEM.

PROGRESS OF FRUIT CULTURE.

JUDGING from what is taking place in the West of England, the rising generation will undoubtedly be better supplied with home-grown fruit than has been the case for some years past. On all sides large numbers of the most serviceable varieties of fruit are being or have recently been planted, and I am informed that the demand for Apple trees especially is so much on the increase that stocks for grafting purposes cannot be bought under at least twelve months' notice. Excessive zeal frequently needs a wholesome check, as it is easy for an enthusiast to err in planting in a wrong place; and also what may not after all prove really profitable to anyone. An orchard situated far away from a large town or from a railway would be a doubtful investment, and should be avoided as much as possible.

Those who are on the point of commencing hardy fruit culture on a large scale cannot be too often warned against putting all their eggs in one basket. In other words, it is most unwise to depend solely upon one or two classes of fruit. It is the mixed orchards that pay much the best in the long run, as in these a general failure rarely, I may say never, occurs. By failure I mean in the sense of no crops resulting, as, unfortunately, it is possible for immense crops of some kinds of fruit, notably Plums, to be obtained, and a loss be the consequence owing to the difficulty of obtaining remunerative prices after railway and other much too heavy charges have been met. The intending planter ought not only to seek competent advice as to what should be planted, but he ought also to look well ahead in order to feel certain he will be able to dispose of his produce to the best advantage. Inexperienced capitalists or landed proprietors who may fortunately have a good sum of

money at their disposal, ought to be told that there are no Heaven-sent or born fruit growers, and all should walk before they attempt to run.

Much depends upon the nature of the soil, and more especially the subsoil, as in some districts it would be little short of madness to attempt fruit-growing on a large scale. I may be told that it is possible to improve and render almost any land fit for fruit culture; but granting this for the sake of argument only, the question yet remains, Would it pay to do this? I say no. A good site may be a decided gain; but here again the question arises, What is a good site? As a matter of fact, the experienced planter would much prefer to establish several orchards in different positions rather than be confined to one site. In this way he guards against a huge failure. The low-lying orchards stood the drought well last year; and thanks to this and the shelter afforded were but little injured by cold winds, and are the most productive this season. At least such is the case as far as my experience goes, and at all events I have it on the best authority that the distributed orchards on one large property are a decided success, no mistake being made in planting in that way, a general failure not having resulted since the outset, or say for five consecutive years. It is the owners of landed property that should do the planting, even if they do not actually conduct the experiment to a successful issue. Not only have they every advantage in their being in a position to select various sites, but they have also the knowledge that they will not, at a short notice, be obliged to quit the land and leave to others the benefits that ought to accrue to themselves. The least that those who rent land can do is to insist upon having it on a long lease, or say not less than a twenty-five-years term.

Some may have been debarred from planting with the idea that several years must elapse before they get any adequate return for their outlay. If any ordinary Apple or Pear orchard is planted, it is several years before much fruit can reasonably be expected; but the experienced or well-advised planter closely crops the intervening spaces till such times as the trees cover the whole of the ground. Rows of bush fruits are planted between the standard trees, and between the former are grown Strawberries. The latter are the first to be productive, and remain profitable till such times as the Gooseberries, Currants and Raspberries want all the space. All the latter eventually make way for the now large and most profitable Cherry, Damson, Plum and Apple trees; and in this manner not more than one or the first season is lost. This introduces another advantage attending the system of extending the planting over a series of years rather than making one large plantation at the outset, as, in addition to gaining good experience as to what is the most reliable, the requisite supply of small fruits is kept up. It is the latter that will always prove the most constantly prolific; and if a ready sale is found for this class of produce will in the end be found the most remunerative.

Here comes in the greatest difficulty all fruit growers, whether on a large or small scale, have to contend with—viz., the uncertainty attending the marketing of the fruit. This ought always to be faced and well thought out before any planting is done. As a rule most small towns are fairly well provided with fruit, or at any rate few are capable of absorbing all that is produced in their immediate vicinity in years of plenty. Of the difficulties and the disappointments attending upon a system of packing and sending the bulk of the fruit to a great distance, there is no need for me to enlarge. This part of the subject is only too apparent to all but quite superficial observers; and if such fruit as Cherries, Plums, Gooseberries, Currants, Raspberries and Strawberries have first to be carted a considerable distance to a railway station, and eventually handed over to the tender mercies of the salesmen in markets, it is a bad look-out for the grower. Enthusiasts overlook this difficulty, and I am afraid have in many instances persuaded others that they have only to grow the fruit, and the demand will follow. On no class does the uncertainty of a fickle climate or the difficulty of effecting ready sales for a glut of fruit fall more heavily than it does on the proprietors or holders of small plantations or orchards. Unlike the large proprietors, they have no system of insurance, their eggs, to repeat a homely phrase, being all in one basket; and as a rule, they find large and regular buyers always prefer to do business with those who can guarantee a good and heavy supply every season. Apples and Pears can be sent away or stored, and good fruit can usually be sold to advantage; but, as I have tried to prove, these alone will hardly pay.

Evidently there is good room for numerous jam factories, and a never failing demand for good, wholesome preserved and bottled fruits generally, as well as for crystallised and dried fruits. One very large plantation or series of orchards is capable of keeping a large factory well employed all the year round; and if a number of smaller growers would co-operate, these, too, might share in the profits attending the business. A factory would absorb all the fruit grown; and if in the hands of an independent firm would

yet give a good price for every hundredweight of sound fruit sent in. I have seen enough of fruit culture in the western as well as in the home counties to convince me that the only wise course of any would-be successful fruit grower is to first arrange for the sale of the produce, as it is very certain the plan most generally in vogue of packing and sending the bulk of the fruit to a great distance is a very risky speculation.—W. IGGULDEN.

DOVER HOUSE, ROEHAMPTON.

THIS, the seat of J. S. Morgan, Esq., is at all times of the year worth a visit, if only to see the manner in which it is kept; indeed, it is quite a Heckfield in that way. Visitors are also sure to meet with a hearty welcome from Mr. Forbes, the gardener in charge, who, if time permits, will not leave much unseen. The entrance to the glass department from the drive leads through a long avenue—not of Wellingtonias or any other choice Conifers, but two magnificent rows of Scarlet Runner Beans, quite a novelty in their way. It is not intended here to give a detailed account of all that was seen during a too hurried run round, but a few principal items. Several houses containing Peaches and Nectarines were passed through, the trees where the crops had been gathered looking the picture of health, while the fruit, ripe and ripening, indicate that they received all the good things necessary for their perfect production. One advantage here was noticed—namely, that the houses, be they for Peaches or Vines, were not crowded with miscellaneous plants. The varieties of Peaches are numerous, while the fruits are particularly well coloured and abundant. The same remark applies to the Nectarines, one tier of Pine Apple was so good as to cause a halt to examine the fine fruits. The vineries do not produce sensational bunches, but good serviceable examples of capital quality. The Black Hamburgs are of a deep black colour not always seen; the Muscat of Alexandria bunches are assuming that clear amber tint so pleasing to the cultivator, while the foliage on all the Vines was stout and leathery, the wood well ripened, showing that enough and no more was allowed to be carried by the Vines, which were about six years old. Tomatoes were especially noticeable, occupying several houses, all showing judicious selection and cultivation. Occupying the front part of some of the houses with the latter were healthy Fig trees bearing good crops.

A capital span-roofed stove about 40 feet long, 18 or 20 feet wide, was well stocked with medium sized and small healthy plants, which will, if they grow at the same rate for long as they are now doing, will soon need more space. In this house was noticed a special feature in the manner of arrangement of the plants. Instead of having the different plants all over the house they were arranged in blocks of one sort, as for instance Crotons occupied a space to themselves, followed by another one of Dracenas, and one of Pandanus Veitchii. Round the edges of the stages *Panicum variegatum* formed a neat edging, and contrasted with the plants above. Upon entering the house splendid trusses of *Ixora DuRoi* were noticed quite dazzling in colour. A good stock of *Anthurium Schertzerianum* was noticeable, also *Cypripediums*, including healthy plants of *C. Sedeni* amongst others, with Palms in variety, just the size for furnishing. Particularly effective was some well grown plants of *Abutilon Sellowianum marmoratum*, the marble-like markings of their large leaves showing to perfection amongst other colours. In a lean-to Melon house were about three dozen plants of *Acalypha musaica* in various sizes from 9 to 18 inches high, having magnificently coloured large leaves, quite the thing for effective decoration. The variegated *Ficus* showed to advantage in the same house. In a Strawberry house were numbers of Maidenhair Ferns in small pots. A lean-to house with a northern aspect was filled at the back with healthy plants of Camellias, such useful varieties as *alba plena* and *imbricata* being well represented. The back wall of one Peach house was well covered with *Heliotrope*. Of Carnations as many as 12,000 are grown, *Gloire de Nancy* and the old Clove being planted in large masses by themselves, the plants showing by the grass produced that they are quite at home. *Souvenir de la Malmaison* is grown here in large numbers and in great excellence. The bedding-out was of the ordinary type usually met with in gardens. Several walls were neatly clad with Irish Ivy.—R.

GROWING PARSLEY FOR WINTER.

THE preservation of Parsley in a fresh and green state during the winter season is frequently attended with much difficulty where the convenience of frames is not available for this purpose. In the more northerly counties, indeed, Parsley is only to be procured at much expense during nearly six months out of the twelve. The leaves of this useful vegetable when grown in the open ground are generally destroyed by frost; but if the circumstances attending their destruction are fully considered, it will be found that the stems are most rapidly affected where the soil is stiff and moist, and where the situation is exposed to cold cutting winds. The plant, however, does not appear to be so delicately constituted but that it may be had with comparative ease all the year if the ordinary conditions of growing the less hardy plants during the winter are observed. Some varieties are, perhaps, more susceptible to cold than others. The finest sample I ever saw was grown on the west coast of Scotland by a village schoolmaster. It was of a beautiful green colour, and of a remarkably vigorous habit; but growing in a low situation and exposed to cutting sea gales, the leaves always died down during winter.

In ordinary situations Parsley may be grown successfully on a border having a south aspect, and protected from the north by a wall. The soil should be light and rich. A quantity of stones and brick rubbish should be laid at the bottom to the depth of 7 or 8 inches, so that the bed may be raised considerably above the general level of the ground, and thus insured against excessive moisture. The surface of the soil being properly raked, seed of the most curled variety that can be obtained should be sown very thinly, either in shallow drills or broadcast, and slightly covered with fine soil. This operation should be begun in May or early in June, and if the weather continue dry frequent waterings will be necessary. The young plants will have sprung up in six or seven weeks, and when large enough they must be thinned out to 5 or 6 inches apart. They will have become large and vigorous by the end of autumn, when a number of stakes should be driven into the ground along each side of the bed. These stakes should be of a thickness to permit of their being bent across and tied together so as to form a series of arches, and strong enough to support a covering of mats, which should be laid over them as soon as the weather becomes frosty and wet. During intense frost, especially at night, it may be necessary to increase this protection by doubling the mats; but this should be removed entirely while the weather is mild. The soil should be kept as dry as may be, and all decaying matter carefully removed from the plants. A bed 4½ feet wide by 10 long will contain as many plants as may be sufficient for an ordinary supply during the winter.

Parsley might also be grown on a sort of rockwork with great certainty and convenience, for on such a structure the roots and stems could be kept in that dry state which is so indispensable to their health and freshness in dull cold weather. For growing it in this way, it is recommended to sow a quantity of seed early in May in a bed of light rich soil on a south border. When the young plants are a little above the ground they should be thinned out to 6 or 8 inches apart, kept clear of weeds and watered as occasion requires. At the end of August or early in September collect a few barrowloads of moderately large stones, selecting such as are best suited for forming a rockwork. They should be longer than broad, somewhat flat or even at the sides, so that they may lie firmly in their places when built up. Any kind of stones which the district may afford will do; but those of a sandy or porous composition should be preferred when a choice is offered. Bricks may also be used, but they are, perhaps, too flat, and do not present those holes and crevices which are desirable in the formation of rockwork, and which may generally be secured by the use of stones. The site being chosen in some sheltered open part of the garden, the stones and a quantity of good friable sandy loam, with some brick rubbish or rubble, should be collected together. The rockwork must be determined according to taste and requirements, in respect to form and size, but there is no use in having it too large. Perhaps the oval form is the most convenient for building such a structure; and if the base is 5 feet long, a pile may be raised with a surface extensive enough to grow a sufficient supply for an ordinary family. The stones used in forming the first tier or layer may be about 8 inches high and kept close together. A quantity of soil should be worked in at the back and sides so as to keep them together, while the centre may be filled with ordinary brick or sandstone rubbish. When the first layer is completed, a portion of the soil should be laid over the stones at the side, and a number of plants of Parsley, taken carefully up from the bed in which they have been growing, should be planted as regularly as possible in all the holes and crevices, their roots being spread out in the soil, and their stems and leaves kept inclined outwards at the margin. Having fixed the plants properly, proceed to erect a second tier in the same way, and so on with the others, till the pile is raised to the height desired; but with the subsequent tiers keep the stones 4 or 5 inches nearer the centre all round, and about an inch or so apart. Every stone should be placed directly over the point which forms the junction of those immediately below it; and every additional tier which is raised must be kept 3 or 4 inches nearer the centre than the one preceding it. In this arrangement of the several tiers the plants will not come directly over another, and the soil will not be washed down from the interstices by rain. If at the time of building the rockwork the weather is dry, the soil about the plants must be well soaked with water; but this must be done by limited supplies repeated several times, for if much water is poured on at once, a portion of the soil will run down. To prevent the action of drenching rains from having the same effect, it will be necessary to provide the winter covering at once. A number of stout ash sticks must be driven into the ground about 12 inches from the bottom of the rockwork, and attached by a good strong cord, so near one another that they may form an open arching figure at the top, and so placed that at any point they may be 12 or 18 inches clear of the plants. A covering of oilcloth or common canvas should be provided, and kept in readiness to protect the mound from heavy falls of rain until the soil has become consolidated round the sides. This covering will also be available during intense frost, when it must be carefully laid over the whole frame of sticks and removed whenever the weather is mild and open. In eight or nine weeks the pile will have become covered with strong healthy plants, which, besides affording a continual supply, will form an agreeable object both in summer and winter. It may be urged that by this plan of growing Parsley the roots are liable to become dry in summer; but in admitting the probability of such a circumstance, we must bear in mind that if the plants could be kept from growing too vigorously during the summer months, they would be in the best condition for preservation during frost. Now the drought of a hot summer would have the effect of retarding them and conserving their energy

until the time when their growth was most desirable. Besides, any extreme dryness could be very easily prevented by timely applications of water.—A NORTHERNER.

ERICA ANDROMEDÆFLORA.

MANY beautiful and distinct Heaths have now become rare in cultivation, and even when these plants were first favourites *E. andromedæflora* was never one of the most abundant. It is, however, a handsome species, and well worthy of attention. It is taller growing than the

FIG 33.—ERICA ANDROMEDÆFLORA.

majority, with long narrow leaves somewhat clustered on the upper portions of the stems. The flowers are exceptionally beautiful, wax-like in texture, the calyx pale flesh pink, the corolla quite a deep red, but there are several varieties, some having the corollas much more deeply coloured than others, while one has pure white flowers. A curiously spotted form has also been described under the name of triumphans. The species and its varieties are early spring flowering plants, and require the same treatment as other hardwooded Heaths from the Cape of Good Hope.

ENGLISH ARBORICULTURAL SOCIETY.

THE above Society held their annual excursion on September 21st at Chillingham Park, kindly granted for the occasion by the Earl of Tankerville. Most of the party met at Newcastle the night before, and

journeyed to Wooler, where excellent provision had been made for them at the "Cottage Inn." In the morning at 9.30 they proceeded in brakes to Chillingham, arriving at about 11 A.M. They were received most kindly by Mr. J. Noble, the resident land steward, and Mr. Henderson, head gardener. Amongst those present were Mr. J. T. Robinson, Rowlandsgill; Mr. Fleming, Tudhoe; Mr. J. Smith, Langley Castle; Mr. B. Cowan, South Shields; Mr. Scott, Newton Hall; Mr. Wm. Fell and Mr. J. R. Brown of Messrs. Wm. Fell & Co., Hexham; Mr. Isaac Batey, Hexham; Mr. J. Davidson, Secretary, Haydon Bridge; Mr. G. Cooper, Gateshead; Mr. and Mrs. Foster, Wolsingham; Mr. Lonsdale, Rosehill, Carlisle; Mr. J. Peebles, Superintendent of Parks, South Shields; Mr. W. F. Taylor of Messrs. Little & Ballantyne, Carlisle; Mr. D. Smith, Scremaston; Mr. J. Matheson, Morpeth; and Mr. Coroner J. Graham, Findon Cottage, Durham.

The party then proceeded to view an old Norman church of date about 1220. There is an old baptismal font bearing date 1670, and a "leper" window is of rare occurrence in churches in the north. These were used for giving communion through to the afflicted, who were necessarily not permitted to enter the church. Close to the entrance is a very fine old specimen of an Elm tree, which is very much truncated. From there the party proceeded to the castle, which is also of Norman origin, is rectangular in form, has an inner court, four towers, the oldest of which bears date about 1100. The party was permitted to visit the state and private rooms, which were very interesting, containing a valuable collection of oil paintings and Japanese cabinets. Amongst the former most noticeable are those by Sir Edwin Landseer, who stayed a considerable time at Chillingham Castle, and limned one of the most remarkable pictures of the wild cattle, which is a standing record of the great artist's ability, and one of his best. The party here was joined by Mr. Jacob Wilson, Secretary to the Royal Agricultural Society of England, and agent to the Earl of Tankerville, who gave the party much valuable information as regards the castle pictures, wild cattle, the parks, Peles, and other interesting information connected with Chillingham Park, which was highly appreciated. From one of the towers a fine view is obtained of the surrounding locality, and the western side affords an especially effective view of the flower garden and grand drives. The garden is one of the old-fashioned sort, a mixture of Dutch, Italian, French, and Old English.

From the castle the party proceeded to view the park and famous wild cattle, where they were then joined by another trusty guide, Mr. Mechi, who has been park-keeper for over forty years, having charge of the wild cattle during that time. He is yet a lithe and hearty veteran, is full of humour, rich in anecdote, and can recount many strange stories of visitors from Royalty downwards. His appointment was through the advice of Sir Edwin Landseer, who has immortalised him in one of his grandest pictures—the death of a bull—along with the Earl of Tankerville gracefully reclining on the shoulders of his horse. On entering the park Mechi called the company together and told them to keep close to each other. The instructions were so imperative that the visitors were only allowed to whisper in case of disturbing the cattle, which are so wild that on the slightest approach of human footsteps they will scamper about for hours in all directions.

The sun was intensely hot, it was about midday, and a steep ascent all the way, still everyone was bent on seeing the cattle. Onward they went under Mechi's indefatigable lead, and were at last rewarded by seeing the cattle browse on what is now called the Prince of Wales' Plain. The spot was very near to where the Prince of Wales shot a fine bull in 1872. There were about altogether sixty-five, and were led by the king bull. They presented a most imposing appearance. They are all white, with the exception of the nose and eyes, which are black; the horns are gracefully incurved, and the tips are black; the back is even and level. Here Mr. J. T. Robinson took an excellent photograph of them. From there the party proceeded by way of the targate ground, where Mr. Robinson photographed the party with an excellent background of *Abies Douglasi*, *Pinus austriaca*, *Picea Nordmanniana*, and other fine Pines. Close by is Ross Hill, 1200 feet above the sea level, which is a very rocky eminence. It is said on a fine day ten castles can be seen from this fine hill. Next the party proceeded to Hepburn Hill, where lunch was partaken of. Some then ascended the rocky eminence, which is nearly perpendicular, to see an old Saxon camp, about 100 yards in diameter. From there the view is splendid. Nestled amongst the growth of fruit trees is the fine old castle with the Cheviot Hills in the distance. The scenery is rugged and wild.

The park is 1500 acres in extent, about 1000 for cattle, and 500 acres in wood. The Fox Nose is a fine belt of trees of Larch, Beech, and Scotch Fir, and in a wood named Wilson's Corner is a Japanese Spruce, 25 feet high, which is rather rare for the district. We saw beyond the

Prince of Wales' Plain a part of the old Caledonian Forest, which can be traced right through to Hamilton. It may be well to state that there is no exact account of the wild cattle, but such a learned authority as Storer states that from anatomical construction they are the pure type of the wild cattle, which were no doubt left intact through the preservation of this part of the old Caledonian Forest. In the home farm there are just now three steers crossed by a short-horn bull, these are three years, two years, and nine months respectively; the two former are a first cross, and are now being fed for show at Smithfield Cattle Market. As these are the first animals ever shown for open sale in the market they are sure to cause a great furor.

Near to the encampment we were shown Hepburn Wood, which is a natural forest, consisting of Alder, Oak, Birch, and Elm. This is another remnant of the Caledonian Forest. Near by are the remains of a very perfect bastille or Pele, the President of the Society, Mr. Cadwallar Bates, having lately published a book on the old Peles, interesting to antiquaries and archæologists, the lower portion of this had also a

from the castle. In one plantation is a fine Silver Fir about 120 feet high, 11 feet 2 inches in diameter, and has about 90 feet of clear bole.

In the main entrance there is a splendid avenue of Lime trees. Near to these is a curious Oak, 22 feet in circumference, for 10 feet high. The base is not rough but very broad. In one of the horse-pasture fields are Oaks, Plane trees, and Limes planted twenty-five years ago, that were about 20 feet high when they were shifted, the operation having proved a great success. From these through King James's Gate we entered the finely terraced garden (fig. 36) already referred to. It is on the west side of the Castle. From the bottom of the grassy terrace is a level plateau of about 130 yards long, the northern boundary is an embattled wall, which is profusely clad with very fine creepers, Clematis Jackmanni, Cydonia japonica, Maréchal Niel Rose, Wistaria, Ampelopsis Veitchi being amongst the number. All the beds are geometrical figures, and as it is a mixture of all the old styles the effect is most pleasing. Some beds of Roses, apparently Fellenberg, are within little Yew hedges, and these margined with Alpines in circles, consisting of

FIG. 36.—CHILLINGHAM CASTLE FLOWER GARDEN.

dungeon. Visiting the castle and gardens again, Mr. Mechi pointed out an interesting reminiscence of fairy lore. Beside a fine Oak tree is a ring nearly oval of about 20 yards in diameter, and in the centre is a hole amongst stones, the herbage is completely worn away, and yet Mr. Mechi, after forty years' constant observation, has never observed a living animal of any kind round it. Of course the reader can imagine the interesting tales of this supposed fairy abode. In a dell there are some fine Coniferae planted in pinetum fashion, including Picea Pinsapo, Cupressus Lawsoniana, 25 feet, Picea nobilis, and some Wellingtonias. Before entering the alpine garden along the Axis Walk are some fine Double Thorns and Hollies. There are also some splendid trees of Spanish Chestnuts, 14 feet in diameter 3 feet from the ground. The alpine garden contains a very fine collection of plants and the American garden also. Hybrid Rhododendrons had made very good growths, and amongst them was Liliun giganteum, with a spike 10 feet high, these spikes had from sixteen to eighteen expanded flowers, and fill the air with their agreeable fragrance. Near it is a fine Yew hedge leading

Sedum acre variegatum, Mentha Pulegium gibraltarica, Sedum glaucum, and Antennaria tomentosa. Phlox beds were also similarly designed. In the centre of some of the beds were Saponaria calabrica, a very bright Malva, its silvery foliage and Perilla nankincensis having an uncommon good effect. Scrophularia and Tropæolum Cooperi were also a pleasing combination. Of course in all these gardens Yew hedges form a conspicuous figure. There were four squares of about 20 yards surrounded with Yew hedges 2 feet high, top quite flat, and inside was neatly mown grass. Against the embattled wall was a fine ribbon border. Yellow and brown Calceolarias were very fine. Scarlet Pelargoniums and Pompon Dahlias formed an effective and appropriate arrangement for this fine flower garden.

The kitchen garden is oblong in form, enclosed in two divisions by very good walls. On entering we were struck with the splendid annual Candytufts we have never observed so large, and the same may be said of Malopes, Sweet Peas, and Sunflowers. The kitchen is well stocked with Apple trees. Mr. Henderson finds Prince Albert do well

amongst the other usual varieties. Peas were in rows 8 feet apart, and were wonderfully good crops of that indispensable vegetable. Amongst varieties we noticed Telegraph very fine and Veitch's Perfection. The gardens were all stocked with vegetables, while on the walls were some fine examples of trained fruit trees. Peaches outside were a very good crop, but it is doubtful whether they will ripen. The glass structures are not very large, but good use is made of them. In three vineries 60 feet long we observed some well-coloured Grapes, berries large, the bunches not very heavy but well finished. The varieties were principally Black Hamburgh, Muscat of Alexandria, Buckland Sweetwater, and on the back wall was a splendid Brown Turkey Fig with large crop of fruits on. We had a quiet drive back to Wooler to dinner, accompanied by Mr. J. Noble and Mr. Henderson. The dinner over, thanks to the Earl of Tankerville, Mr. Noble, and Mr. Henderson, the success of the Society by the Chairman, Isaac Body, Esq., the reply of the Secretary, Mr. Davidson, and a quick run to catch the train brought to a close the happiest and most memorable outing that the Society has had.—BERNARD COWAN.

EVENTS OF THE WEEK.—On Tuesday, October 9th, the Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster. The Crystal Palace Hardy Fruit Show opens on Thursday, October 11th, and continues until Saturday. A conference and meeting of the British Fruit Growers' Association will be held in the Crystal Palace on the first day of the Show at 2 P.M. Sales of bulbs will be held on Monday, Wednesday, and Saturday at Mr. J. C. Stevens' rooms, King Street, Covent Garden; on Monday and Saturday at Messrs. Protheroe & Morris's rooms, Cheapside; and on Monday, Wednesday, and Friday at Messrs. Smail and Co.'s rooms, 123, Fenchurch Street.

— **NATIONAL APPLE AND PEAR CONFERENCE AT CHISWICK, OCTOBER 16TH TO 20TH, 1888.**—A meeting of the Executive Committee was held in the Royal Horticultural Society's Gardens at Chiswick, on September 27th. Present—The Rev. W. Wilks in the chair; Messrs. Bunyard, Cheal, Herbst, Walker, Hibberd, Dean, Hudson, Turner, Rivers, W. Paul, and J. Smith. Papers to be read at the Conference were promised by Messrs. G. Bunyard, J. Cheal, J. Douglas, E. Tonks, S. Hibberd, J. Fraser, W. Wildsmith, E. J. Baillie, M. Dunn, McDonald, Tallerman, T. F. Rivers, Saunders, Bear, and W. Paul. Great interest was manifested in the proceedings, promises of support being received from the leading growers. It was agreed that the Conference be held in the Conservatory on Wednesday and Thursday, October 17th and 18th, the first day (October 16th) being devoted to the examination of the fruit, the General Committee meeting at 3 P.M. for the formal opening of the proceedings. It was agreed that no prizes be awarded, but cards of commendation for special merit will be given by the Committee. It was decided that the various papers be put in type, previous to the Conference, for the more convenient use of the Committee and press. The Gardens will be opened to the public at 1 P.M. on October 16th. Notices of intention to exhibit should be sent to Mr. A. F. Barron, Royal Horticultural Society's Gardens, Chiswick, not later than Wednesday, October 10th.

— **SUCCESSFUL ORCHARDING.**—We hear that 5 tons of Green Gages have been sent to market from the Mentmore orchards this season, and that the fruit realised 7s. 6d. per bushel.

— **MARIE LOUISE VIOLETS.**—I send you a bunch of Marie Louise Violets. We have been gathering for several weeks from the open border, and are now about to remove our plants to their winter quarters in frames, where they will, all being well, supply us with frequent and valuable gatherings right up to the month of May next. Had we a failure with our winter Violets we should miss them indeed. —JOHN CRAWFORD, *Coddington Hall Gardens, Newark-on-Trent.* [Beautifully fresh and fragrant were the blooms received, and our correspondent may well appreciate them.]

— **ARAUCARIA IMBRICATA CONING.**—For the information of the Rev. W. W. Wingfield I may say these trees cone freely enough in

various parts of England, even in the inhospitable climate of Derbyshire. I have had fertilised and matured seeds that readily germinate, but as the trade prefer foreign-grown seeds our home-grown are not worth the trouble required to produce them. I believe the ovule-bearing trees are more common than the pollen-bearing trees, as they are more frequently met with. I think they are readily distinguished by their dwarfer habit and dense compact dome-shaped heads. The female cones are green and grow erect on the points of the top growths; they take two years to mature, and attain a large size. The male or pollen-bearing trees are much taller growing and looser in habit; the catkins are brown, pendant, and they grow in clusters mostly on the points of the side branches, and sometimes at the junction of the one and two-year-old wood. The tallest male tree we have is 72 feet high, the tallest female 46 feet high.—J. H. GOODACRE, *Elvaston.*

— **THE WEATHER.**—We have to-day (October 1st) experienced most exceptional weather in the Leeds district. Changing from sharp frost during early morning, rain commenced about 9 A.M. At 10 A.M. snow began to fall heavily, continuing until noon. The hills on becoming clear presented a most unusual picture, while taking a nearer view of various forest trees in full foliage borne down, of which English Elms, Purple Beech, and Spanish Chestnut, were truly grand, if such a term may be allowed; with 1 inch groundwork of snow the effect of scarlet Pelargoniums may be imagined.—E. BURTON.

— **FROST AND SNOW IN HARVEST.**—Writing from Lincoln, a correspondent says:—"A sharp frost was experienced in the north of this county on Monday morning, the 1st inst., the roads being crisp and ice quarter of an inch thick. Dahlias, Tropæolums, Vegetable Marrows, and Kidney Beans were blackened in some gardens, but many escaped. Heavy rain fell from midday till evening with large flakes of snow. The bulk of the harvest is gathered in, though much remains to be secured. Apples and Pears are small, the crops light, and late in maturing."

— **GARDENING APPOINTMENT.**—H. Charles, late foreman to the Right Hon. Lord Dynevor, Dynevor Castle, Llandilo, South Wales, has been appointed head gardener to the Rev. F. B. Teesdale, Whitminster House, Stonehouse, Gloucestershire.

— **AT Messrs. Harkness & Sons' nurseries, Bedale,** long beds of GAILLARDIAS, &c., are in robust health from seed sown out of doors in March and transplanted when large enough in September or the following spring to where they are to flower. I saw varieties in bloom there fully equal to the high-priced ones, and the Gaillardia is a very easily cultivated plant.

— **THERE** also can be seen many thousands of plants of the ICELAND POPPY in full bloom, proving that it is of the easiest cultivation, and should be in every garden. I was astonished to see the great breadth of ground set aside for these plants.

— **ABOUT 7000 plants** from seeds of MRS. SINKINS PINK was another surprise, and with such luxuriant growth. Mr. Harkness succeeded in 1887 in saving seed which was sown in October in cold frames, and the seedlings planted out in nursery beds early in April this year, and a great many of the plants are now flowering, some differing from the parent, and many promising breaks amongst them, but the true test will come next spring. It was refreshing to see their deep-green healthy growth, over 1000 plants have blooms, and not a single variety amongst them. Messrs. Harkness & Sons exhibited thirty blooms of these seedlings at the great Show in Manchester in September, and they received a great deal of attention.—D. S.

— **CARDIFF CASTLE GARDENERS' ASSOCIATION.**—The second session of this Association was successfully inaugurated on September 25th by Mr. A. Pettigrew reading a paper upon the "Cultivation of the Pear on Walls." As it was previously determined to throw the Association open to the gardeners of the district, there was a large attendance, the syllabus made out for the session being a very attractive one.

— **THE HESSLE PEAR.**—As a free-bearing hardy orchard Pear this has no equal in the eastern counties. It is the only variety that is producing profitable crops in many orchards, some of the trees being of immense size and yielding from 50 to 100 pecks of fruit. They are in great demand in the markets, and large consignments are sent to London. The fruit is somewhat smaller than usual, below medium size, not particularly attractive in appearance, being brown and russety, but the quality is excellent, the peculiar flavour finding acceptance by most palates.—A TRAVELLER.

— WE regret to learn that Mr. F. A. DICKSON of CHESTER died on Thursday last, September 27th, in his sixty-third year. He was the son of the late Mr. Francis Dickson, and the chief partner in the firm of F. & A. Dickson, of the Upton Nurseries, now amalgamated with J. Dickson & Son, as Dicksons (Limited). Mr. F. A. Dickson was elected Sheriff of Chester in 1868, and in 1870 was chosen as Mayor; he also held several other local offices of importance, and was much respected.

— GLADIOLUS BRENCHEYENSIS.—This Gladiolus is capital at this time of the year planted among low-growing Heaths, Kalmias, Andromedas, hardy Azaleas, or dwarf shrubs, or around the edges of Rhododendron beds. The bright spikes give considerable colour to the otherwise dull-looking beds at this time of the year. The peaty soil also allows the Gladiolus free opportunity to root well, and consequently to send up good spikes of bloom. We plant the corms each year in March, taking them up in the autumn.—S.

— WHAT an excellent window plant is VALLOTA PURPUREA. It is largely used in the country both by amateur cultivators and cottagers; it seems to stand much hardship when not in bloom, and it is often thrust on one side to make room for a more showy plant. This kind of treatment appears to agree with it, as when September comes around again the same pot full of bulbs can be seen producing a number of showy spikes of flowers. One thing in its favour, it is not over-potted as a window plant, that and the rest it obtains through lack of water no doubt are in the favour of its flowering.—E.

— AT this season of the year TRITOMAS look well anywhere, but nowhere do they show to greater advantage than when planted singly on the grass, their brilliant spikes of bloom contrasting well with the green surroundings. Planted close to the edge of water they succeed admirably. Where T. glaucescens and T. Uvaria are both planted the flowering period is prolonged a considerable time, the former being the first to throw up its flower heads, and by the time they are over the latter is at its best. A fairly rich deeply trenched soil, and a good soaking two or three times during the summer with liquid manure, help the plants considerably.

— FUCHSIAS are conspicuous in some beds at Battersea Park, and attract attention. They are also well represented in the flower gardens attached to some of the houses in the town of Hitchin, the plants being large and bushy, and loaded with bloom, remaining in perfection for a long time. Some of the older varieties, such as Rose of Castile, appear to predominate. In window boxes they are also freely employed, the drooping kinds hanging down and hiding the boxes completely. Ecermocarpos scaber, Tropæolums, and Cobæa scandens are trained up trellises over some of the doors and windows, rendering the town very interesting and attractive.

— A PLAGUE OF FLIES.—Mr. Bardney writes:—"Last week we were much troubled with small black flies. At times it was almost impossible to see for them. I think they are the ordinary green, black, and brown aphides. The Wheat has been covered with them. I fancy they are now on the wing, and if the weather continues mild and warm everything will be smothered with them. I am borne out in this opinion by the fact that those on the wing rendered our Peach trees inside nearly black, but we regarded them as harmless creatures. But this has not been the case, for nearly every leaf is covered with green, black, and red or brown aphides. The old ones are dead and dying. The spiders have been busy, for their webs are full of these annoying pests."

— GOOD PEACHES AND NECTARINES.—In my last note on Peaches and Nectarines for the open wall I quite forgot to mention "Dymond," which is so highly spoken of by Mr. H. Markham. I can fully endorse the praise he gives it, as we have a capital tree now bearing about seven dozen fruits at about a foot apart. The size is equal to any good Royal George grown under glass, and the colour very dense. It is now turning in, and the flavour is first-rate. I don't know whether other people's Peaches are the same, but those here are very highly coloured this season, in fact more so than last. The colour of the Nectarine is very deep. Dr. Hogg we are now using, and it has proved itself a good Peach out of doors.—A. YOUNG.

— IN the garden of J. H. Tukes, Esq., Hitchin, are very interesting ALPINE ROCKERIES, and a large herbaceous border, 150 yards long, is effective at the present time. Tropæolum speciosum is a brilliant hardy climber, and is growing and flowering freely against a wall trailing over some sticks that have been placed there. Another useful hardy climber is found in Passiflora Constance Elliott, which is also trained to a wall; it is loaded with its lovely white flowers hanging down in

graceful festoons. In the tropical fernery above the rockery is growing a fine fruiting plant of Monstera deliciosa, reaching the full length of the house, with the long roots hanging down yards in length, apparently quite at home in the heat and moisture. Mr. Springham is the gardener.

— I LATELY saw in the gardens at ROOKSBURY PARK, near FAREHAM, a very effective circular bed containing a large plant of Tritoma glaucescens in the centre, bearing a profusion of large richly coloured flower spikes; around it were planted thinly roots of Helianthus annuus fl.-pl., the double perennial Sunflower. The combination of colours was very pleasing, looking down upon the bed from a distance and from higher ground. It is surrounded by a neatly kept undulated lawn, upon which are growing a good number of specimen Conifers. On the lawn in the same garden is a circular bed containing a dozen or more plants of Yucca filamentosa, now in flower, which produce a pretty effect both in the distance and upon a closer inspection, much more so than would the same number of plants dotted about in the shrub-beries.—B.

— EUCHARIS GRANDIFLORA.—I read with much interest Mr. Record's useful article on the treatment of Eucharis grandiflora. There is no doubt it will stand a cooler temperature than many people imagine. I once tried the plan. I wanted some plants to flower about the middle of November, and mine had been in flowering in July and again about January. After the flowering in January, I grew the plants on in the stove until the middle of March, then removed them to an intermediate house for about six weeks, thence to a cold pit, ultimately placing the plants outdoors in July, where they remained until the middle of September. The situation was shaded after twelve o'clock in the day. The plants received a good share of water or the foliage would have gone. As it was, however, the foliage certainly suffered somewhat, but not so much as might have been expected. When the plants were transferred inside, I first placed them in the intermediate house for a week or two, where they very soon began to show flower spikes. They were then returned to the stove, and I think these flowered better than at any time I had charge of them. The flowers were ready about a week earlier than intended, but I was highly satisfied with the experiment, as also was my employer.—J. P.

— I WAS much interested in Mr. Record's experiment with Eucharis grandiflora, because I have practised the same method of treatment for several years though not to induce blooming, but to check the ravages of that pest, the Eucharis mite, which had got hold of our plants and greatly crippled them. In this the open air treatment has been completely successful, and it is satisfactory to find that the much-dreaded Eucharis disease can be conquered in so simple and inexpensive a manner. Our plants, like Mr. Record's, have usually been partially shaded when standing out, but I begin to doubt whether a more sunny position is not preferable. Certainly those which have been so placed this summer look more robust than the others. We give a month more of fresh air than your correspondent does, as our plants have only just been put under cover, and even now are in an unheated greenhouse.—B. D. KNOX.

— CHICHESTER GARDENERS' MUTUAL IMPROVEMENT SOCIETY.—The first annual Exhibition of this Society was held on Monday evening, September 24th, in Little London, and was, on the whole, a decided success. The Society was formed in July, 1886, and monthly meetings are held, at which various subjects relating to horticulture are discussed, and certificates of merit awarded for the best productions. No prizes were awarded at this Exhibition, nor was there a charge made for admission, which had the effect of bringing up many hundreds of visitors. The Exhibition was really held to test the strength of the Society, with a view to holding future shows on a larger scale. The Committee had sent out invitations nearly all over the city, but there was no necessity for this, as the Show was extensively patronised. The principal exhibitors were Councillor Gatehouse; Mr. Kent, Salt Hill; Mr. Aylward; Mr. P. Robinson, The Warren; Captain Phillips; Mr. Clifford, Shiers, Cawley Priory; Mr. J. McDonald; Mr. H. H. Moore; Mr. Ayling, gardener to Dr. Tyacke, J.P.; Mr. Gardner, gardener to General Hardy, C.B.; Mr. Pusey, Hon. Secretary to the Society; and Mr. Hobbs. The exhibits comprised fruit, flowers, plants, and vegetables, and were without exception, of fine quality. Councillor Gatehouse's Orchids were much admired; Mr. Moore's cut flowers were a conspicuous feature in colour and variety; Mr. McDonald's "fire screen," artistically made up of various flowers, was a finely executed piece of work. Mr. Clifford exhibited a splendid group of Ferns; and Mr. Gardner's Dahlias were notable for their good quality. During the

evening a string band, organised by Mr. Pryer, a member of the Society, played a capital selection of music.

A CHRYSANTHEMUM SHOW IN CINCINNATI.

THE "American Florist" announces a grand Centennial Exhibition of Chrysanthemums at Cincinnati, Ohio, from October 22nd to October 27th next, when some extraordinary prizes will be offered. Only fourteen classes are enumerated, but the prizes range from 250 to 5 dollars. For "the best display comprising the largest number of well grown plants, all kinds," the prizes are £50, £30, and £10. For "the best fifty plants, all kinds," £20, £10, and £5 are offered, with £10, £5, and £2 for twenty-five plants. Smaller prizes are also offered for plants in such classes as the following:—"Best ten white," "best ten yellow," "best ten pink," and single specimens in the same way. There are only three classes for cut flowers. The first is for "the best display in variety, not less than 300 vases or glasses," the prizes being £20, £15, and £10. The others are of a similar character, with prizes from £10 to £2.

CHRYSANTHEMUMS AT DOVER HOUSE, ROEHAMPTON.

CHRYSANTHEMUMS are largely grown in the garden to produce large blooms, and from their appearance they will do so. Several hundreds of plants are cultivated for this purpose, the majority occupying a position in a newly acquired kitchen garden, a row of plants standing on each side of a high path in such a manner that they miss the winds and are exposed to the sun; in fact, just the spot a cultivator would choose. The plants run on the big side as regards the wood and foliage, but nevertheless it is ripening well. Thunberg is 8 feet high, other sorts in proportion. Very fine in appearance are the plants of Val d'Andorre; 10-inch pots are mainly used, and the plants had not needed much feeding beyond occasional supplies of soot water. The Queen family perhaps showed a soft appearance rather as compared with the other varieties. In this garden the Rundles and Glennys are still considered worthy of a place.—R.

JAPANESE CHRYSANTHEMUM DORÉE.

THIS new variety belonging to the early-flowering section is now flowering in the nursery of Messrs. W. & G. Drover, Fareham, and a very pleasing variety it is; the colour is a soft yellow or deep primrose. The flower is of medium size; the florets reflex thoroughly, forming a full bloom. It is a useful addition to the early-flowering class.

EARLY-FLOWERING VARIETIES.

This section of Chrysanthemums was well represented at the late Crystal Palace Show by the groups there staged in competition for the prizes offered. By far the best as representing the greater variety was that from Messrs. Davis & Jones, Camberwell, London, containing as it did the best kinds in this section. Intending growers of this section of the Chrysanthemum could not do better than select varieties from the undermentioned, which I noted as being the most meritorious. Mdle. Leonie Lassali, creamy white, very free flowering, of good form; Miss Davis, fine pink sport from Mrs. Cullingford, the flowers of good form; Mrs. J. R. Pitcher, flowers soft pink, of capital form; Torcador, small flower of a bronze colour; Mignon, this is a capital sort, very profuse bloomer, dwarf compact habit, deep rich yellow. Salter's Early Blush, a rosy blush-coloured flower; Nanum, creamy white, perfect formed flower, free; St. Crouts, very free, pink in colour; Lyon, a bright rosy purple; Alice Butcher, a sport from Lyon, colour at commencement a deep red changing to orange; Flora, a bright yellow, very free; Blanche Colomb, creamy white; not forgetting those favourite varieties Madame Desgrange, G. Wermig, and Mrs. Burrell.—E. M.

THE season has not been one of the best for Chrysanthemum growers generally. After a late cold spring a succession of dull wet weather setting in made a vast difference in the wood produced compared with last year, when the wood was as hard as Hazel. However, we have had three weeks of fine weather, which has improved the appearance of things much in the respect of the ripening process, though our plants which are grown for large blooms average a foot higher than last year, but there seems every chance of good solid blooms.

Our summer-flowering varieties have done well this season, perfecting well-formed blooms with full centres, which is sometimes a fault in summer varieties, having what is termed black centres. We have a good number of Madame Desgrange, G. Wermig, and Mrs. Cullingford, which we are beginning to cut freely. The two former are opening far better than they did last autumn, though the plants have been rather closely packed for want of room; consequently the wood is soft, though the plants have abundant healthy buds. Mdle. Leonie Lassali, a sulphur-white variety, is of a good stiff habit and very free, is about ten days

earlier than Madame Desgrange. La Vierge is pure white, flowering through October, fine for cutting or for pot plants; this is also a dwarf stiff-habited variety. Anna Liabaud is not so satisfactory, the flowers not coming perfect. The above varieties may be relied upon for a succession of useful blooms until Lady Selborne, Mdle. Lacroix, and Elaine begin to open.

Earwigs have been troublesome; these are now disappearing, but green fly attacked the plants about ten days ago, and seem likely to be troublesome until we get the plants housed, when fumigating thoroughly will be tried. Tobacco powdering or syringing is of little use, as the pests are seeking protection on the under leaves as the nights become colder.—A NOTTS GROWER.

SEASONABLE WORK.

EVERY attention must be paid to those plants that are to yield large flowers. The majority must be under cover, and the remainder placed where they can be protected or lifted inside in case of frost. Early frosts often compel the housing of these plants to take place before it would otherwise be necessary, the thermometer having already fallen 2° below the freezing point. These light frosts do not appear to do harm, but they do the plants no good, and protection from such influences should be provided. When the plants are housed be careful not to crowd them, for it is important to preserve their lower foliage until the last. The preservation of the foliage insures the activity of the roots, which must be farther assisted by top-dressing and judicious feeding. Admit abundance of air at first and avoid unduly exciting the plants, or the flower buds will come forward too rapidly to insure their being of good size and perfect form.—A GROWER.

NATIONAL SOCIETY'S CATALOGUE.

IN looking through the above Catalogue I note that in the characteristics of incurved it is said the bloom should be as nearly a globe as possible. In my opinion this would have been better had it read in this way—"The incurved flower should be of globe form, but as much deeper as possible." With all good judges and growers the depth of an incurved bloom is the most essential point. What would be done if a second prize winner declared that the first prize blooms do not correspond with the characteristics of an incurved bloom should the stand contain flowers which are of extra depth? Qualified adjudicators will always acknowledge depth in a bloom as the first consideration, and I fancy deep flowers are more easily found at the present date than they were, say, fifteen years ago.—E. MOLYNEUX.

REVIEW OF BOOK.

The Tuberous Begonia, its History and Cultivation. By CONTRIBUTORS TO THE "GARDENING WORLD." London: 17, Catherine Street, Strand, 1888.

IN a compact book of 106 pages is embodied all the information that can be required concerning the Tuberous Begonia, representing the work of several hands, prepared under the direction of Mr. B. Wynne. The history of the species, the origin of the cultivated forms and their culture both indoors and out, are treated at length in several chapters. Numerous illustrations are given of the leading varieties or types, and portraits of Mr. R. Pearce, Mr. John Laing, and Mr. H. Cannell are also included.

The following extracts give some idea of the scope of the work in the historical portion. The cultural instructions are reliable and elaborate.

THE FOREST HILL STRAIN.

"It was in the year 1875 when Mr. John Laing of Forest Hill whose portrait we have the pleasure to introduce into these pages, after some years of patient labour bestowed on the improvement of many of our most important florists' flowers, turned his attention to the Tuberous Begonia, for which he believed there was a grand future as a greenhouse decorative plant. How he has succeeded in the development of the plant to a pitch of excellence at first undreamed of all the world now knows, and we can only express our regret here that we are unable to give more than a general idea of how the marked improvement has been brought about by him. Mr. Laing commenced cross-breeding with *B. boliviensis*, *B. Veitchii*, *B. Pearcei*, and the following varieties—Vesuvius, Dr. Masters, Mrs. Masters, and Dr. Hooker; but the seedlings obtained in the following year were not of a promising character, but little improvement being visible. He then obtained all the varieties he could get of other raisers, both at home and on the Continent, which he crossed with his own seedlings, and *vice versa*; and the next season had the pleasure of raising several sorts which were decided improvements. This little success gave a fresh impetus to the work, and by adding to his stock the best new varieties sent out by other growers, and a few seeds, carefully fertilised, from the finest sorts, had the results of fifty-seven different crosses to sow in January, 1878; and from these sowings great advances were obtained. In the summer of the same year Mr. Laing exhibited at South Kensington a group of seedlings which fairly startled the floral world, and to which the Royal Horticultural Society awarded its gold medal, many of the varieties being also distinguished by the award of first class certificates. Then was the Tuberous Begonia characterised as 'the coming flower.'

"In the same year the Messrs. Veitch sent out their Queen of Whites, which turned out to be a splendid seed or pollen parent. Mr. Laing crossed it with Henderson's White Queen, and *vice versa*, and in 1879

obtained some 500 seedlings, all of which bore white flowers, and which marked a great improvement on all the white-flowered varieties then in cultivation. They varied greatly in habit, but all bore fine flowers, and a selection of the tallest-growing sorts was named *Reine Blanche*, while the dwarf growers were matched and named *Stanstead Bride*. The former was certificated the same year, as also was *Stanstead Rival*, a variety selected out of the same batch, which marked the greatest advance of all, and which was the first variety that had nearly erect flower stems and round flowers. Other fine seedlings raised the same year were *Princess of Wales*, *Lady Hume Campbell*, *Exoniensis*, and *J. S. Law*; and some fine dark seedlings, among them being a very small, nearly black variety, of no use for general cultivation, but which was kept for hybridising purposes, and which was one of the progenitors of the splendid dark crimson bedding varieties which were so much admired by all visitors to the Messrs. Laing's nursery last autumn.

"In 1879 renewed energy was thrown into the work of cross-fertilising, Mr. Laing having so many improved flowers to work upon, and in the spring of the following year he had 161 different crosses from single and double varieties, *Stanstead Rival* being the most extensively used variety on account of its stiff habit and erect flower stems. *Reine Blanche* and *Lady Hume Campbell* were also extensively used, and from the seeds obtained that season were acquired still further advances in shape, size, substance, and colour, in the latter point especially. The later sorts obtained at Forest Hill have been obtained by constantly selecting the largest and finest shaped flowers for crossing, the results therefrom being the grand strain now offered as '*Royal Begonias*.' Mr. Laing has truly done wonders for the *Begonia*, and in no way can this be better illustrated than by comparing the flowers of the first hybrid, *B. Sedeni*, with one of Mr. Laing's greatest achievements, *Queen Victoria*.

THE SWANLEY COLLECTION.

"Some two years after Mr. Laing took the *Begonias* in hand, Mr. Henry Cannell commenced their cultivation at Swanley, and as showing what progress he has made, we may mention that in 1877 he offered for sale only nine *Begonias*, including *B. octopetala* and *B. Froebeli*, which, as we have before observed, have taken no part in the production of the magnificent varieties of the present day. *Sedeni*, *Dr. Masters*, *Stella*, and *Vivicans* were among the tuberous varieties, offered together with *B. boliviensis* and *B. Pearcei*. The following year thirty-eight sorts were offered for sale; but four of them do not belong to the tuberous type as now recognised. The greater number of these were of continental origin, and few of them now figure in collections containing the more modern improvements. Three doubles were mentioned—namely, *Louis Van Houtte*, *W. E. Gumbleton*, and *Argus*, together with a semi-double, *Notaire Beaucarne*. In 1879 twelve doubles were described, and ninety-six singles, including six of other species. A good sprinkling of them originated in this country, including *White Queen* and *Queen of Whites*, but still the continental productions were most prominent in this collection. The doubles numbered twenty-two, and the singles about a hundred in the following year, necessitating classification into different colours, of which the variety even then was most wonderful. In 1881 the double varieties numbered twenty-nine, and in the following year forty-two, with a corresponding increase of single-flowered sorts. At least thirty-five of the double forms were of continental origin, and even at this time they began to show some of the freaks and peculiarities for which they are noted. Some of the flowers mimicked those belonging to other natural orders, and a new section was created for those having serrated margins to the sepals, an indication of a tendency to revert to ordinary foliage leaves.

"More progress seems to have been made with the single varieties in this country, and six are specially mentioned as having been raised by the Messrs. Cannell, including three yellow and two buff coloured varieties, which owe their origin to *B. Pearcei* as one of the parents. A house of 150 feet in length was set apart for them at Swanley in 1881, and what is equally interesting, a number was planted out in the experimental garden there, and which withstood the following winter, flowering well the succeeding year. The double varieties numbered fifty-two in 1883, and were mostly or all, as before, of continental origin; in 1884 they numbered sixty-five; in 1885 forty-four of the older varieties, together with thirty-five new ones, are described, including the beautiful late-flowering *Camellia*-formed white *Octavie*. In 1886 112 doubles were described, including seventeen new ones obtained from France and Germany. Last year (1887) 119 doubles were described. An inspection of them shows that they have mostly been derived from *B. Veitchi* and others of that type, having broad leaves and broad rounded petals; a few have also been obtained from *B. Davisi*. During the last year or two Mr. Cannell has been most successful in raising double varieties, and now possesses a number which mark a great stride onwards. Some dozen or more of these will be offered next season.

"Mr. Cannell cannot be described as a raiser of the *Begonia* in the same sense as Mr. Laing, but he has grown them by tens of thousands, and has rendered horticulture good service by constantly introducing the best of the continental novelties, and exhibiting them in a condition that few can surpass. Mr. Cannell during the last quarter of a century has been a power for good in the horticultural world, inasmuch as that, perhaps, no man during the same period has sent out so many grand florists' flowers. During the same period, we must also add that he has, by indomitable pluck and energy, built up a business of con-

siderable magnitude, and that, too, under circumstances which would have deterred many another man from attempting the task."

GRAPES SCALDING.

THE discussion on this subject grows more interesting. Mr. Simpson in your last issue advances some very pretty theories, but I am sorry to say they are unaccompanied by hard facts. It is an easy matter to advance ideas, but quite a different matter to substantiate them. I have given some stubborn facts, none of which Mr. Simpson has cleared away. He wishes to remind me that *Lady Downe's* and *Black Hamburgh* grown in the same house cannot be compared, for they would not pass the critical stage at the same time. But what if they were treated alike till they had both passed the stoning process? The case I placed before your readers, page 261, was where *Lady Downe's* is planted in an early *Black Hamburgh* house, and the former scald while the latter never lose a berry. I will now endeavour to show Mr. Simpson that both varieties did pass through the stoning process under the same conditions. When the *Black Hamburghs* commenced stoning, a light was left open a little way above the Vine of *Lady Downe's*, and the bottom light also on hot days (which were very few). Now that light was never moved except for rain during the whole period, and the ventilation always given so as to prevent the condensation of moisture on the berries. If both are as liable to scalding, I say, why did one variety escape and the other suffer?

Mr. Simpson repeats that *Black Hamburghs* grown with little heat are as liable to scald as the other variety in question. I think I have proved conclusively that such is not the case, for the *Black Hamburgh* did not receive more air as suggested by Mr. Simpson, as the secret of their generally escaping the evil. Again I say there is no comparison relative to the scalding propensities of these Grapes. Mr. Simpson says that the treatment of the range in question being exactly alike accounts for the evil. How so? Neither would he think of treating early and late Grapes alike, neither should I. But when they are all started in March and ripened in September I fail to see where the comparison comes in in this particular case.

I still adhere to my former statement that it would require gross carelessness to scald *Black Hamburghs*, but not so the *Lady Downe's*. Mr. Simpson asks if it is gross carelessness to scald the one, what is it to scald the other? Well, I should say slight mismanagement, for the slightest cause will scald *Lady Downe's*, but I have never accomplished the feat of so treating the *Black Hamburgh*, for I still hold it a feat. I have no pet theory to advance why *Lady Downe's* should scald more than other Grapes; but still the fact is there. If, as our friends would have us believe, it is entirely due to atmospheric conditions, I say why should it scald more than other varieties? If due only to external surroundings, why should not the thin-skinned varieties be affected? For to me it appears feasible that a thin-skinned variety should scald sooner than a thick one. I am fully convinced that the reason why Grapes scald more than others under the same circumstances has yet to be explained. As I am always open to conviction, I shall be pleased to acknowledge it if any reader can explain the reason satisfactorily.

I see that there is one point that Mr. Simpson and myself are agreed upon—viz., we do not object to a few degrees rise or fall in any fixed temperature. I feel flattered in obtaining such an admission. Strange to say, the "fixed temperatures" Mr. Simpson so kindly gives for my future guidance have been my fixed temperatures during the past season, of course allowing the few degrees either way. Our night temperature was 65° as nearly as possible, and the airing of the house during the day, especially the early morning, was always to guard against the condensation of moisture on the berries.

Like Mr. Simpson I take great interest in Grape culture, and shall be pleased to obtain any further information on the subject. I think the subject of great importance to all gardeners alike, and I trust they will come forward with their opinions on the subject.—JAMES B. RIDING.

I HAD not overlooked Mr. B. Riding's communication on pages 260 and 261. I have been waiting Mr. Young's reply in the last issue. I gladly welcome the spirited criticism that my letter has brought out. Three correspondents are agreed that it is "fancy" on my part to affirm that *Black Hamburghs* will scald as badly as *Lady Downe's*, and which can only be accomplished by "gross carelessness." If a professional gardener of the stamp of Messrs. Riding, Young, and Kirby had scalded their *Black Hamburghs* until their bunches were "bits" instead of full bunches it might be termed "gross carelessness;" but with the young gardener or amateur growing Grapes perhaps for the first time any such accident could not be due to carelessness on their part, for they may have exercised every care that their knowledge warranted. It was the inexperienced I tried to instruct, and amongst whom I did not include your three correspondents; but I can already perceive they too have something to learn on this subject, and therefore my communications may be of service to a wider circle than I had anticipated.

All three would lead us to believe they repudiate the theory that scalding is constitutional, and yet they are firm believers in the theory if we draw conclusions only from their writings. If it is not constitutional with *Lady Downe's* (do not misunderstand me, I argue that it is not), why should that variety be subject to scalding and all other varieties not? This they say is the case, but the arguments they have adduced do not prove that they are right and I am wrong. If I admit for the sake of argument that to scald the berries of *Black*

Hamburgh as badly as Lady Downe's is "gross carelessness," I do so conditionally that the scalding of the latter is due to the same cause. I have never suggested that these two varieties grown together in the same house would both scald, but I should be surprised if Lady Downe's did not under the conditions to which it is subjected by Mr. Riding. On this point Mr. Simpson has hit the right cause. The Black Hamburghs will have completed the stoning period long before Lady Downe's, and the treatment it is then subjected to is the cause of scalding. The treatment the former receive after they are stoned is too forcing for Lady Downe's during the critical period of stoning.

Your correspondents have overlooked one of the main points to which I attributed scalding. They will find in the third paragraph, page 162, that I there wrote, "Overforcing, whether due to an increased temperature by sun heat or the anxiety of the cultivator to push the crop forward when Nature requires to move slowly, will certainly end in scalding, to a greater or less extent according to the amount of forcing to which the Vines may be subjected." Here is the secret of Lady Downe's scalding in Mr. Riding's two early houses. Overforcing at that critical period will cause Black Hamburgh or any other Grape to scald. Who would expect anything else to take place when Lady Downe's and Black Hamburghs are grown together? Who would expect Sea Eagle or Walburton Late Admirable Peaches to do satisfactorily in an early house with Hale's Early Peach or Lord Napier Nectarine? If the two latter had the treatment they required to bring them forward quickly to have them ripe as early as possible, who would be surprised if the two late varieties threw off the whole of their fruits or split their stones? If complete success with the latter was anticipated, then the early varieties would have to be materially retarded in their favour. Why should Grapes be an exception? Take the early Peach and Nectarine named; overforce them during the stoning period, or just before they have finally completed stoning, and what would be the result? Would not a fair percentage of the fruit fall, if not all? Why, then, should your correspondents single out Black Hamburghs and other early and midseason Grapes as not being liable to be affected in the same way? Scalding is not always due even in the case of Lady Downe's to "gross carelessness" in ventilation. Natural conditions over which the cultivator has no control render it next to impossible to regulate the day temperature to prevent it proving too forcing to this particular Grape during the time it is stoning. Overforce in like manner Black Hamburghs or any other variety during the time they are stoning, and I will guarantee any of your correspondents can scald them as badly as Lady Downe's. Ventilate as freely as you like in the morning, and until the temperature commences declining, and then close the house so as to run up the temperature considerably, and the berries will be scalded. This can be done before and after the stoning period without the slightest harm. Shade the house but maintain a high temperature, and the berries will be scalded. I think this is clear that scalding is not entirely due to the action of the sun striking on the berries while they have condensed moisture upon them. My advice then is, whether the Grapes are early or late, to let Nature at this critical time take its course, and suspend, as it were, for the time being forcing operations. It is wiser to err on the side of keeping the temperature rather too low than to attempt to excite the Vines at this stage. The only certain way of carrying Lady Downe's safely through the stoning period without scalding (I am writing of those growing in a late house) is to raise the night temperature slightly and ventilate the structure during the day like a greenhouse, so that the Vines have time to complete the important work in which they are engaged. During bright hot weather keep the day temperature as low as possible, and the cultivator will be rewarded with bunches, not "bits."

Mr. Young says the latter part of my article needs no comment if I keep to the text; it is merely a comment upon the matter be introduced into his first letter, and which if foreign to him is not foreign to the subject at issue. It is perhaps convenient for Mr. Young to ignore those portions of my article that tell against him. It is, to say the least, only a poor way of conducting a discussion—to pass over questions that need an answer by asking questions in return. But the amusing part of Mr. Young's letter is, that he asks questions on a matter that is practically foreign to the subject, and at the same time advises me to stick to the text. What has the price of Grapes to do with scalding? The market grower to whom I alluded syringes his Grapes until they commence colouring; all the varieties that he grows receive the same treatment in this respect. The work is not done by experienced hands. Last year I saw the Grapes, and the work had been entrusted to a boy who had never had anything to do with Vines before. His reward for keeping the Vines free from red spider was a new suit of clothes in addition to his wages. He earned it, and I have no doubt received it. The quality of the Grapes may be judged when it is stated that some of them were staged last year against those from such men as Messrs. Hunter and McIndoe, and gained the premier position for six bunches amongst ten competitors; again, first for Alicantes, seven showing in the class; third for any other black with Lady Downe's; for the heaviest bunch of Grapes, second with Alicante. That is not a bad record at one show, and in company of some of the best Grape growers in the country. Is this grower for the market "worthy of the name?"

"What causes moisture to condense on the berries?" asks Mr. Young, and he answers this question by saying, "Why, an overheated atmosphere, caused by the sun shining suddenly on the house without sufficient ventilation, as well as insufficient heat in the pipes to prevent the

berries becoming cold." This is, I should think, the vaguest statement on the condensation of vapours that has perhaps ever appeared. It would be as well if Mr. Young would take the trouble to look up somebody's theory on the "Liquefaction of Vapours." The condensation of vapours may be due to three causes—cooling, compression, or chemical affinity. Condensed moisture on the berries of Grapes is due to a low temperature; and the berries being naturally colder than the atmosphere, they cool the air in contact with them, and the consequence is some of the vapour it contains is quickly deposited. As the temperature rises the air takes up the moisture which it has previously deposited, and the result is evaporation. Instead of condensation taking place when the temperature rises, evaporation takes place and the air is charged with heated vapour that practically "stews" the berries unless means of escape for it have been provided. Condensed moisture is a natural process, and vapour is deposited in the form of dew under natural conditions most nights in the year, and why should Grapes be an exception, that it should injure them? The condensed moisture does no harm, but harm is the result of the artificial treatment to which the Vine is subjected by not providing means of escape for the moisture evaporated by the sun raising the temperature.—WM. BARDNEY.

It is very good of Mr. Simpson of Knowsley to give your readers, and Mr. Riding especially, what he appears to consider an infallible recipe for preventing the scalding of the berries of Lady Downe's; but as I have practised that system for some time without obtaining the results promised I fear Mr. Riding will not benefit very materially by following the advice; but probably he has already experienced failure under the conditions laid down by Mr. Simpson. When I took my present charge I acted on the experience acquired under one of the best Grape growers of his day in this or any other country in so far as the vineries are concerned, but I did not obtain immunity from the scalding of Lady Downe's. I had ventilation when the temperature rose to 70°, still scalding was prevalent. It was given at 6 A.M., scalding continued. The ventilators were left slightly open at the top and lower part of the house all night; but all of no use, scalding of Lady Downe's continued. Finding that the evil was not to be checked by usual or unusual methods of ventilating I turned my attention to the "damping" process. Orders were given for the late vinery to be damped once only in twenty-four hours. After two or three days there was an apparent diminution of scalding, but not an entire cessation. However, this was encouraging; we were on the right track. The word was passed that water was to be entirely withheld. This was done; and as soon as the atmosphere was as dry as it is supposed to be requisite to have a Muscat house when the Vines are in flower scalding ceased. The fire was kept going night and day from first to last, and the ventilators were kept open night and day until the berries commenced colouring. The vinery is heated by a flue. There are two fixed lights at the top at the east end and one at the west end. The front ventilators consist of small shutters 18 inches by 10½ inches opening inwards, and from the bottom upwards fixed in the front wall. The nearest lower ventilator is 4 feet from the end (east). The angle of the roof is about 60° from the horizontal, or 30° from the perpendicular. I give these particulars because the vinery in some respects is similar to the kind indicated by Mr. Bardney. Under the fixed lights at the east end is one Vine of Black Hamburgh. This never has any scalded berries. The next six Vines are Lady Downe's; then follow two Gros Colmans which never scald; and the last are three Muscats which are liable to be scalded by the western sun if not shaded.

Mr. Simpson's dictum that Black Hamburgh does not scald when grown under the same conditions as Lady Downe's, because the former is slightly in advance of the latter, is as fallible as his rule for prevention of scalding. The Black Hamburgh has less air, but yet is only about ten days in advance of the Lady Downe's at the stoning period; and as the scalding and stoning periods vary from three weeks to six weeks, it follows that both must be under equal conditions for scalding so far as that is concerned, but according to Mr. Simpson the Black Hamburgh is under the worst conditions, because it is not "so freely ventilated," and therefore the "secret" is a myth, a mere fancy.

It is a notorious fact that Lady Downe's is prone to scald up to the colouring period under conditions that such kinds as Black Hamburghs would be safe, and whether it is constitutional or not it remains a fact and is not a "fancy." I am aware that it is possible to grow Lady Downe's without scalding taking place, and I have so grown them, but it was in a vinery having ventilators the whole length of the house, and glazed with rolled glass. The question at issue is not whether it is possible to grow Lady Downe's without scalding taking place, but whether it is more prone to scald than other varieties grown under equal conditions, no matter what those conditions are. Mr. Bardney did not qualify his conditions.—A. BIGHTER.

In answer to Mr. Simpson, the cause of Lady Downe's Grape being more likely to scald than any other Grape is a physiological subject beyond me. Probably some scientific readers would advance their opinions. I fail to see any logic in Mr. Bardney's question to me. The inconsistencies advanced by Mr. Simpson in support of his argument or theory will probably be answered by Mr. Riding.—A. YOUNG.

YOUR correspondent Mr. Young is quite right in saying that Lady Downe's scalding can be prevented by those in charge. A few years since in the south of England I was troubled by Lady Downe's scald-

ing. To remedy it I left ventilation on during the night, kept the pipes just warm, and discontinued damping in the morning, which I found was the best course to adopt. I have never found other Grapes scald if ventilation is attended to early in the morning, and think it would be gross carelessness if Black Hamburgs or other Grapes were allowed to scald.—T. SLADE.

THE MADRAS AGRI-HORTICULTURAL SOCIETY.

IN the course of the annual report issued by the above, the following notes occur on tropical plants introduced or cultivated in the Madras presidency through the influence of the Society:—

ECONOMIC PLANTS.—The grievous depression amongst the planting community of Southern India mentioned last year unhappily still continues and paralyses private enterprise in the direction of new introductions. The stock of such plants is, however, still kept up in the Society's nurseries in hopes of better times reviving the demand. Numbers of Maragogipe Coffee, Erythroxylon Coca, Lance Wood, Mahogany, Landolphia, Trincomallee Wood, Edible Prickly Pear, and other useful plants are still available.

CHOCOLATE.—The large tree of *Theobroma Cacao*, under the shade of the Coconut Palms, succumbed to the drought, but another plant a year or two younger growing near it not only survived, but seemed not to suffer. The old plant was isolated in the grass, so had no protection but the shade overhead, and got only such water as was given to it directly by hand; while the survivor is in the new border closely surrounded, sheltered, and shaded by the Coconut Palms and the young trees and shrubs in the border, and got the full benefit of the periodical floodings of the border. The Honorary Secretary is still of opinion that the cultivation of Cocoa might very possibly be successful in Madras if the cultivators would take the same trouble as the growers of the Betel Leaf do in Bengal, to shade, shelter, and irrigate their crop.

RUBBER PLANTS.—The Landolphia plant successfully ripened its crop of fruit, and from the seeds Mr. Gleeson raised about eighty plants, which were in due course placed at the disposal of Government for further experiment. Orders have been issued to various officers to take over the plants and try them in climates and situations which are expected to be favourable to their growth and development. The *Castilleja elastica* plants still thrive.

BREAD FRUIT.—A batch of root-cuttings of the tree which bears the seedless Bread Fruit was obtained through the kind offices of Mr. Logan, the Collector of Malabar, and the Superintendent hopes to raise from them a few good plants. A large rooted plant was also obtained by Mr. Robinson, the Chief Engineer of the Madras Railway, from the western coast, presented to the Society, and planted at once in the Coconut tope where it is showing great promise. Three other fine plants are thriving, planted out in the gardens, two having been presented by Mr. Lavery, and one being the survivor of a number received from Dr. Trimen, Ceylon. In view of Mr. Lavery's success in growing and fruiting the tree, and of the healthy and vigorous appearance of the young trees in the gardens, the Committee sees no reason why this tree, such a safeguard from famine as it might be, should not be found growing by the side of the channel of every irrigation well in Madras. The Committee is informed that Mr. Lavery has interested several of the wealthy Brahmans living in and about Mylapore in the subject, the produce of the tree being specially suited to the needs of their community. The Society is of course willing, and anxious, to do its best to obtain plants from Ceylon or the western coast, for everyone who is prepared to pay the cost, which should not come to more for each plant than that of a young grafted Mango.

TREE TOMATO.—The Committee still hears frequently from the hills of the great success of its introduction, thanks to Mr. Morris of Jamaica, of *Cyphomandra betacea*. Unfortunately the plant will not grow on the plains, but in the cooler climates of Southern India it is an unqualified success, and its popularity continues to increase. Happily its fecundity is so great that the Society has no difficulty in complying with demands for seed by applying to some of its correspondents in more favoured localities.

PRICKLY PEAR.—A few inquiries have been made during the year for plants of the Edible *Opuntias* introduced from Cyprus and Malta, but no report has yet been received of their success. In the Society's Gardens plants of both are well established and growing freely, but have not yet fruited or even produced perfect flowers by which they could be identified. The Society's collection of *Cactaceæ* has been greatly enlarged by gifts from Poona, Calcutta, and elsewhere during the year, and it is hoped that progress may shortly be made in naming them all correctly; but, with the exception of the naturalised species, and two or three others, plants of this order do not appear to flower freely in the climate of Madras.

CARLUDOVICA PALMATA.—In August, 1887, three plants of this Palm were received in a Warden case from Dr. Henry Trimen, Director, Royal Botanic Gardens, Ceylon. Two of them unfortunately died, but the third promises to grow well, and is now five or six times as large as they were when they arrived. The following interesting account of the plant and its uses is extracted from the "Treasury of Botany":—"Common in shady places all over Panama and along the coast of New Grenada and Ecuador. Its leaves are shaped and plaited like a fan, and are borne on three-cornered stalks from 6 to 14 feet high; they are about 4 feet in diameter and deeply cut into four or five divisions, each of which is again cut. The Panama hats commonly worn in America,

and now becoming common in this country, are manufactured from these leaves. Those of the best quality are plaited from a single leaf without any joinings, and, as the process sometimes occupies two or three months, their price is very high, a single hat often costing 150 dollars, and cigar cases of the same material £6 each. The leaves are cut whilst young, and the stiff parallel veins removed, after which they are slit into shreds, but not separated at the stalk end, and immersed in boiling water for a short time, and then bleached in the sun."

PARITUM ELATUM (The Mountain Mahoe).—Seeds of this plant were received from Kew on 19th July, 1884, from which a few plants have been raised. Two of them have been planted in the border in the Coconut Tope where one of them is very promising, being now about 23 feet 9 inches high, and 9 inches in girth, at 3 feet from the ground. It is stated that this plant "affords the beautiful lace-like inner bark called Cuba bast, at one time only known as a material used for tying round bundles of genuine Havannah cigars, but afterwards imported, particularly during the Russian War, as a substitute for the Russia bast, used by gardeners for tying up plants; it is now largely substituted by other materials. The tree, which is found only in Cuba and Jamaica, grows 50 or 60 feet high, and yields a peculiar greenish-blue timber, highly valued by the Jamaica cabinet-makers."

MORINGA.—A species of this tree, *M. pterygosperma*, Gaertn., is well known to Anglo-Indians as the producer of the "Horse Radish" used on the plains, and less generally as the supplier of the main constituent of "Drumstick curry." There is another representative of the family with finer and more beautiful foliage in the gardens, where it has stood a solitary specimen for many years without flowering. Interest was excited in the subject by "The Kew Bulletin," which, in its first number mentioned another species which produced a tuberous root, reported to grow, and be valued as food by the Arabs in the Desert. The Honorary Secretary wrote to the Director of the Royal Gardens, Kew, on the subject, who kindly sent the Society, in May last, three roots which he described as "in the resting stage." From the account given of this plant it would probably be a very valuable introduction.

INGA DULCIS.—As usual the Society has sent on application to Ceylon, Penang, and all parts of India, particularly the north, large quantities of this invaluable and most versatile tree. It is probably the most universally cultivated tree in Madras, being as general for hedging and nearly as good as the Hawthorn in England. It bears any amount of clipping and chopping, or worse, nibbling by sheep and goats, and gnawing by horses and cattle. If attended to it forms an impassable fence, if neglected grows into a noble "Bullfinch." It sows itself and grows on all waste land, and that even with its roots in salt or brackish water. Single or surviving hedge plants grow into grand timber trees. The timber is used by the husbandman for cart building; the wood is specially appreciated by the brickmaker; the leaves and twigs furnish a never failing forage for the poverty stricken feeder of milch goats; birds, beasts, and boys scramble for the plump arillus which encases its seeds; and in the hot weather while the grass is too dry to be eatable, the hungry cattle eagerly devour the tough outer pods.

CASUARINA MURICATA.—Experiments and inquiries are now on foot to ascertain and bring to notice the value of this tree as a producer of timber useful for building purposes, pavement, and other economic uses, as it seems positively wicked to chop up trees 100 feet high, straight as a dart, and girthing at breast height 5 or 6 feet, for fuel, which is practically the sole use to which they are now put. Mr. Chisholm, the late Consulting Architect to Government, has spoken very highly of the timber for building purposes; and Mr. Thorowgood, the Engineer of the Madras Harbour Works, is now making experiments with it for the pavement of level-crossings over the Beach Railway. Mr. Thorowgood's experiments are yet in their infancy, but it is believed that the traffic will prevent the white ants, the bane of woodwork in the tropics, from doing much mischief, and that the cement in which the blocks are set will prevent warping, to which this wood, being immature, is specially liable. Should the trial be a success, it may be expected to revolutionise the dusty thoroughfares of Madras.

On 29th April, 1879, papers were read before the Institute of Civil Engineers which, amongst other facts, demonstrated that hard tough wood should be selected to creosote, creosoted beech pavement on Sunderland Bridge having worn less in fourteen years than granite sets in four years; that it is an absolute necessity for wood pavement that it should have a thoroughly good concrete foundation, and that the cost of maintaining wood pavement to get seven years' life from it is one-eighth, and of scavenging one-sixth of Macadam. With such facts before us there can be no doubt of the advantages of wood pavement generally, and there appears to be every probability that *Casuarina* timber will, on fair trial, be ascertained to be specially well suited for the purpose. The planting of the tree on a large scale has been practised for so short a time, and the wood has been so much used in an immature state for fuel, that comparatively little mature timber has been handled, but in hardness, toughness, density, and specific gravity it is almost unrivalled. Hard wood is scarce and costly in Europe, and if it should appear on experience that *Casuarina* wood is equal to or better than other woods in use, Madras has in her hands a source of almost incalculable wealth.

Another reason why experiments which may lead to the retention of growing trees till they reach something like mature age should be pressed and encouraged, is that the price of *Casuarina* wood for fuel has fallen during the last fifteen months nearly 30 per cent.; large plantations in the market can find no purchasers, and petty owners are grubbing up their young trees to realise before the price falls still lower without

any intention of replanting. Should large clearances be made followed by the abandonment of the fuel-planting enterprise, the results may be disastrous. The indigenous and established sand-binding plants have been smothered by the Casuarina trees, and the consequence of the removal of the latter can only be the transformation of, at a moderate estimate, fifty miles of coast line north and south of Madras, metamorphosed in the last twenty years into fine forest, into a chain of bare and blowing sand-dunes, the inland edges overlapping and hopelessly destroying the cultivated land, while those on the seaside contribute a liberal quota to the already surcharged streams which threaten to choke the new harbour.

KITCHEN GARDEN.

MUSHROOM BEDS.—Those who have been collecting material for Mushroom beds lately should now make them up. Cultivators differ in opinion as to the best position for beds. Some adhere to the old heated houses, others grow them in sheds and outbuildings, while many make up the beds in the open and grow them well there. We approve of all ways so long as they suit the grower and the beds are made up the same in all cases. As is well known, horse droppings are the best of all materials for Mushroom growing. We have known good crops produced from manure from the cow sheds, but prefer the horse droppings, only the beds need not be exclusively composed of these. Turf and soil, and even leaves, may be mixed with the droppings. We have often placed pieces of soil as large as the fist in the beds, and when the Mushrooms appeared some of these were crowded with them. The manure should be gathered into a heap, turned over frequently to allow the superfluous moisture to escape, and do not add the soil until the bed is about to be made up. If the soil is very dry it will be an advantage, as it will absorb the moisture from the manure and prevent it heating too much. The beds may be from 3 feet to 5 feet in width, and from 1 foot to 18 inches in thickness if they are under cover, but if in the open they should be made up like a Potato pit with a ridge about 4 feet up in the centre, and a sharp slope to each side. The manure should be trodden and beaten as firmly as possible, the object being to make it retain the heat until the Mushrooms are growing freely. We have lately formed a bed in the potting shed. It was made one day and spawned the next. Two days afterwards the thermometer indicated 90° as the temperature of the bed, and now it is 95°, but the heat will not increase, and the holes in which the spawn were inserted, although left open to allow the superfluous heat to escape, will be closed in a day or two and the soil put on. As long as the temperature does not rise above 100° there will be no harm done. Indeed, a high temperature is necessary to make the spawn run and penetrate the bed everywhere. We have known Mushroom beds fail through lack of heat, and when they were broken up the pieces of spawn were as hard as on the day they were inserted.

TOMATOES IN THE OPEN AIR.—The recent bright weather has improved these a little, but not sufficiently to make the crop of 1888 a success. There is now no chance of this, and this is the worst season we have experienced for Tomatoes in the open during the last dozen years; but one bad year in twelve is not discouraging, and in another year we shall try to extend their culture in the open, as it is an easy way of securing much good fruit. Our plants have failed to gain their usual strength, and the fruit is scarce, but the most must be made of what has been formed, and care should be taken that none of it be injured by frost. A few degrees will make the fruit spotted and diseased, and then it is useless, but if the fruit is cut off before it is injured and hung up in a warm glass house or room it will ripen slowly, and prove very useful in November and December. The fruit does not require to be fully grown to ripen in this way, as those not over half grown will ripen as well as those that are fully developed.

LATE VEGETABLE MARROWS.—Peas and some other choice vegetables are not so plentiful as they were, and as autumn advances it will be more difficult to secure variety, but Marrows may be kept on for a long time. Many of the fruits are ripe and hard, indeed unfit for cooking, and if these are allowed to remain on the plants until the leaves die more young ones will fail to form, but if every old fruit is cut off numbers of young ones will form and swell at once, and these will give a supply until about Christmas. We always secure fine late young Marrows by being careful in cutting the old and matured fruits at this time.

KIDNEY BEANS.—Both the runners and dwarfs are exceedingly tender. The slightest frost will destroy the foliage, and then the supply of pods will cease. The dwarfs are the easiest to manage in late autumn. Where they are in good condition still and growing in close rows, if some frames are placed over the best of them and cover them with lights at night the supply may be kept for some weeks after the exposed ones are destroyed. Hoops and mats placed over a few rows are also beneficial. Our latest runners are in flower, but we fear they will never form pods. Quantities have been gathered from earlier rows

and sent into the kitchen to be salted in jars for winter use. When this is properly done they may be served on the table throughout the winter, and very few will be able to toil them from pods newly gathered. Where pits for forcing are numerous a sowing of dwarf Ne Plus Ultra Kidney Beans should be put in now. Fill sixty, eighty, or one hundred 3-inch pots half full of good soil, place six or eight seeds in each, put a little more soil over them, and stand them near the glass in a house or pit where the night temperature is about 70°, or a little less. Here the plants will appear in a week, and when from 4 inches to 6 inches high transfer them into 7-inch pots. Two or three may be placed into each of the larger pots, and if well supplied with light, air, and heat they will grow robust and prove very fruitful by December.

TYING UP ENDIVE.—The best way to blanch autumn Endive is to gather the leaves up all round, forming them into a cone-like shape, and then tie them firmly round the top that they may retain this form. If done when quite dry wet will not readily reach the centre, and they will remain sound and good for a long time.

FRUIT FORCING.

PINES.—To maintain the sturdy healthful appearance of young growing stock free ventilation is necessary, maintaining the bottom heat about the roots at 80°, watering the plants whenever they require it. Employ weak liquid manure occasionally, and avoid using the syringe too frequently; merely sprinkling the paths every morning and evening will suffice. Fire heat must be resorted to to maintain a night temperature of 60° to 65°. Fruiting plants should have a night temperature of 70°, 80° to 90° during the day, closing at 85°. Newly potted plants must have a bottom heat of 90° to 95°, with a view to the roots speedily penetrating the fresh soil. Recently started suckers should, as soon as roots are plentifully made, be raised near the glass, it being essential that those intended to be wintered in small pots be brought on very gradually.

When the suckers started this autumn are well rooted they should be potted without delay, draining the pots well. Employ the fibry part only of turfy loam, and do not tear it up too fine, but use it in lumps proportionate to the size of the pots. The strongest plants may be transferred to the largest pots at once, the size of the pots being proportioned to the robustness of the varieties. Black Jamaicas do well in 9 or 10 inch, Queen in 10 or 11 inch pots, Smooth-leaved Cayenne and similar varieties in 11 to 12 inch pots, and Providence in 13 or 14 inch pots, which will afford fruit. Where smaller plants and fruits are the objects aimed at, pots an inch or two less in diameter will answer. The plants not of a suitable size for transferring to the largest pots may be shifted into 8 inch pots, in which they should be kept until spring.

STRAWBERRIES IN POTS.—Watering Strawberries for the coming forcing season must not be neglected, though plants in well drained soil in the open ground do not suffer from continuous rains, yet those in pots are seriously injured by continued needless waterings, especially those required for early forcing, still they must never be allowed to become dust dry. Any that have the soil very wet and remain so for a time without watering should have the drainage seen to, as worms or the material upon which the pots are placed choke the outlet, rendering the soil sodden, in which no plants will thrive. The crowns are often numerous in some varieties, especially Vicomtesse Hericart de Thury, a number of small crowns clustering near the central one. The small should be removed as soon as they can be taken with finger and thumb, leaving the central or strongest crown. This will concentrate all the vigour of the plant into the chief crown, and though there will be fewer trusses of flowers there is no need to fear a deficiency of crop, and it is essential that a forced Strawberry above all things be large and red. Give the plants sufficient room for the exposure of the foliage to light, keeping the plants free from runners, and the pots cleared of weeds.

CHERRY HOUSE.—If it is intended to plant any trees it should be seen to as soon as the leaves begin falling. The Cherry—indeed, stone fruits generally, thrive best in a calcareous soil, turfy loam with a sixth of chalk or old mortar rubbish, being careful to have it free from pieces of wood, as old laths, &c., and if deficient of grit add a similar proportion of road scrapings, and to this may be added a twentieth of steamed crushed bones. If the soil be light add a sixth of clay marl finely divided, the whole to be thoroughly incorporated. Provide a drain of 3-inch tiles with proper incline of the bottom of the border to it, and the drain having due fall and sure outlet. There should also be 9 inches, or better 12 inches, of drainage, the roughest at the bottom, with the material diminishing in size upwards to that of road metal, and if the top 3 inches be of chalk or the rougher parts of old mortar rubbish it will be an advantage. A depth of 24 inches of border is ample, and 6 feet width will meet all the requirements of trees grown under glass, and the compost should be placed together firmly. Black Tartarian and May Duke are the best varieties; but the yellow forms an excellent addition to the dessert when fresh fruit is not over-plentiful. Early Jaboulay, Elton, and Governor Wood are first rate. The lights having been removed they need not be replaced for a month or six weeks, the old surface soil being removed without injury to the roots and replaced with fresh compost, that above named answering with the addition of a fourth of manure.

Trees in pots required to be shifted into a larger size should be attended to at once, and those not required to be so treated should be turned out of the pots, removing a few inches of soil from the base, cutting back the roots, and supply fresh loam, adding old mortar rubbish and a sprinkling of crushed bones, good drainage being provided. Remove the surface soil, adding the above compost, with a

fourth of good manure. Afford a good watering, and place the trees where they can have plenty of air.

VINES.—*Preparing for Early Forcing.*—Where the roots have the run of outside borders it will be advisable to prepare some fermenting materials for placing on that part about the time the house is closed, the border in the meantime being protected from heavy cold rains by spare lights or other means. Two-thirds of Oak or Beech leaves to one of fresh stable litter thrown into a heap, moistened if necessary, and turned over a few times, will afford a durable heat and suitable source of nutrition. Similar material should also be prepared for placing inside the house, which will aid the Vines in starting through the uniform state of the moisture and heat, and lessen the necessity for fire heat. Thoroughly cleanse the house, everything being put into proper order, and keep the house as cool as possible. Vines that are to be started early in December should be pruned at once (if not already done), so as to allow them some weeks of rest before starting.

Earliest Vines in Pots.—These start more freely if a slight bottom heat can be afforded; a bed of fermenting materials, two parts leaves and one part stable litter, afford a mild lasting heat. Place loose brick piers so that their rims are level with the top of the fermenting bed, and the fermenting material brought up about the pots loosely in the first instance, and not to have a temperature at first of more than 70°. Vines that have been ripened early, pruned, and had about six weeks' rest, may be started at once. The temperature at starting should not exceed 55° by artificial means, but when the buds show signs of breaking it may gradually be increased to 65°. The canes should be slung in a horizontal position to induce them to push their buds evenly throughout the length of the rods, syringing them three or four times a day.

Late Houses.—Vines that were judiciously forwarded by fire heat in the spring and onward till now have crops of ripe well-coloured Grapes, which will keep much better than those that still require fire heat. Liberal ventilation on all favourable occasions will be required, and as the foliage is matured the temperature may be allowed to fall to a minimum of 50°. Mats or a light covering of clean dry straw placed on the inside border will prevent the rising of moisture. The Grapes should be looked over twice a week for the removal of decayed berries, but if properly ripened and the house drip proof they will give very little trouble. A supply of fern where the common bracken is plentiful should be cut for covering late house borders for the winter. A good covering of bracken is quite equal if not superior to litter as a protection. Late Grapes not yet ripe must have fire heat briskly by day, with a free circulation of air, and the temperature must not be allowed to fall below 65° at night, and to assist the ripening of the wood keep lateral growths closely stopped.

The present is a good time to lay in a stock of materials for forming Vine borders. The top 3 inches of a pasture where the soil is a good friable loam is suitable for Vines, and should form the staple of the compost. Place it in somewhat narrow ridges, and have the top ridged so as to throw off the wet. It is better got now than when soaked and cold from rains.

PLANT HOUSES.

Zonal Pelargoniums.—If not housed those for flowering early in November must be placed under glass at once. Water carefully at first and start them gently into growth. If they are hurried after they are housed they are liable to make a quick soft growth and fail to flower profusely. Those intended for later flowering should have the protection of glass; cold frames will suit them better than houses for a few weeks. All they need for the present is protection at night and from heavy rains. Give these abundant ventilation on fine days by throwing off the lights.

Salvias.—If not already lifted this should be done without delay; it will also be necessary to place them in a position where they can be shaded from the sun for ten days or a fortnight, and at the same time easily protected with canvas in case of frost. If they are well watered directly they are potted and then liberally syringed afterwards they will not be long before they are rooting freely, and will bear exposure to the sun.

Heliotropes.—The whole stock of these must be housed without delay, for they are not safe outside; even if they escape frost the temperature at night will fall too low for them. The earliest may be started with the Zonal Pelargoniums, and the remainder should occupy a light airy position in a cool house. For the present the temperature in cool houses will not fall low enough to do them any harm.

Tree Carnations.—The earliest plants may be housed. Select for them a cool, airy, light position, not too far from the glass. It is important that the pots be stood upon some moisture-holding base. Tie any shoots that need it before housing them, and examine the base of the pots to see that worms have not stopped the drainage and thus prevent superfluous water making its escape. A little artificial manure may be applied to the surface of the soil, and the plants gently fumigated if aphides exist upon them. The remainder of the stock, or those for spring-flowering, will be safe outside for another month.

Mignonette.—Tie down the shoots of standards and pyramids; if any of the plants are required in bloom in a month select those that are well furnished and allow the shoots to extend. Be careful that they do not become dry, or the shoots will soon become woody, and small instead of large spikes will be the result. Give abundance of air to encourage strong growth, and lightly syringe the plants twice on fine days. Give a little artificial manure to the surface of the soil at intervals of two or three weeks to keep the roots active. Be careful not to allow any of the plants to become rooted into the moisture-holding

material on which they are standing. A number of those in 6 and 7-inch pots grown for cutting may be allowed to flower if seed was not sown to be covered with a frame for yielding a late supply.

Tea Roses.—Plants in pots that are bursting into new growth may be placed indoors. Give them abundance of air by day, and in a month or six weeks they will yield a capital supply of buds for cutting when those outside are nearly all over for this year.

THE BEE-KEEPER.

HOW TO BEGIN.

NOTWITHSTANDING the inclement season some friends of local and hitherto successful bee-keepers have pressed us once more to give instructions to those who desire to set up in the industry of bee-keeping; and although we are fully conscious that such information can only be given in these columns at the expense of some reiteration, it is perhaps not misusing the space at our disposal if we comply with their wishes, and once more point out to those who desire to know what is the best and most expeditious means of starting an apiary at this season of the year.

It is hardly necessary to say that those who follow our instructions in a half-hearted fashion, and only in part carry out what we deem to be the essential features in the method, should not expect to be successful. On the other hand, any man of average intelligence who will follow the instructions to the full need have no fear of failure. The end of October is certainly rather a late period to commence, but it is not too late to make a start upon the very method which we think it advisable to instruct the beginner to adopt.

The novice must first find a stock filled with well built worker comb headed by a young and fertile queen, and certainly at the very least three or four swarms of bees. The hive must admit of at least twenty standard frames being used, and on no account must a stock located in one of the little abominations containing only eight or nine frames be purchased. One who has had but little experience can hardly expect to tell the value of a queen, and if the purchaser doubts the word of the vendor the only test he can apply is to examine the combs and see whether there are patches of brood, and also to notice whether there appears to be a more than normal amount of old bees. A young bee can easily be distinguished from an old one by its grey colour and the more perfect state of the wings of the former. An excess of drone comb is very detrimental to a stock, a very small population is fatal, and a worthless queen absolutely disastrous. But if we can find a hive filled with well built worker combs, some of them containing brood in various stages, even if the population is comparatively small, there need be no fear in making the purchase, even if the combs do not contain a sufficiency of store to carry the stock over the winter and spring, because the population can easily be augmented and a sufficient supply of food afforded.

When a stock answering the above description has been met with and the purchased hive removed to its new stand, means must at once be taken to add sufficient bees and to supply the necessary food. Some 5 lbs. of bees should be obtained either by purchase or in such other manner as may offer, and then those bees may be added to the stock in the following manner. A sheet must be spread on the ground in front of the stock, and a little warm syrup prepared, taking care that the syrup is very thin. In the evening, about dusk, a few puffs of smoke must be injected at the entrance of the stock, and then the driven bees must be thrown down on the sheet and well sprinkled with syrup, when the body box of the stock hive containing both bees and combs must be lifted from its stand and placed above the bees on the sheet, the sides of the hive being propped up by bricks to prevent crushing the helpless homeless insects. In a few minutes a happy hum will resound, and early next morning the hive may be replaced upon its stand. Now is the time for feeding up the stock. This may be done in at least two ways, for either sealed

combs containing sufficient honey may take the place of the empty ones already in the stock, or syrup may be supplied in large quantities until the necessary amount of food has been stored and sealed. The large round tin feeder is one of the best possible for rapid feeding. This feeder must be placed at the top of the hive immediately over the clustering bees, and must be replenished every evening until the stock has taken from 15 to 30 lbs. of syrup. The amount will be regulated according to the estimated weight of food already in the combs, but not less than 25 lbs. of sealed store should at the end be left in every stock for winter and spring use. It is false economy to spare sugar and spoil the stock. These are the necessary instructions given in a concise form, and they are sufficiently simple to enable everyone who desires to commence bee-keeping to do so with a reasonable prospect of success.

The following points need special care:—

- 1, Large population.
- 2, Good queen.
- 3, Abundance of food.

We may add that bees removed from a situation less than from one and a half to two miles distant from their old location return to their accustomed place, and many of them are consequently lost. This point will need care.

The above method is only one of many plans, but it has always appeared simple, easy to carry out, and inexpensive. To add other methods might rather confuse than instruct the novice, and we therefore hesitate at present to add more than has already been written lest some gaining a little knowledge only of the principles of more advanced bee-keeping should use that imperfect knowledge to the destruction of their own interests.—FELIX.

TRADE CATALOGUES RECEIVED.

W. Paul & Son, Waltham Cross.—*Catalogue of Roses, 1888-1889.*

Charles Turner, Royal Nurseries, Slo. gh.—*Catalogue of Roses, Fruit Trees, and Nursery Stock.*

J. Cheal & Sons, Crawley, Sussex.—*Catalogue of Trees, Shrubs, Roses, and Fruit Trees.*

All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Address (A. W., Leicester).—The address you require is Mr. J. Witherspoon, Red Rose Vineries, Chester-le Street, Durham.

Chrysanthemum Catalogue (E. T.). Write to Mr. W. Holmes, Frampton Park Nursery, Hackney. The price is 1s. 1d. post free.

American Papers (T. C.).—The *American Florist* is published at 54, La Salle Street, Chicago. You had better write to the publisher, who will give you the information required.

Hoya carnosa (T. G.).—Fruits are occasionally produced by this

plant, and the peculiarity you remark about the seeds is a characteristic of many members of the same family, the Asclepiadaceæ.

Fruit Trees for South-east Wall (Idem).—Cherries and Plums are the most suitable, but it may be used for Pears, such as Jargonelle, Williams' Bon Chrétien, Fondante d'Automne, Doyenné du Comice, Pitmaston Duchess, and Durondeau.

Celery (R. B.).—The Celery is infested by a fungus, and altogether appears to be in an exceedingly bad condition. Cut off the worst leaves and possibly the others may come clean, but the soil must be unsuitable in some way, and if you have a good stock it would be wise to destroy these plants.

Orchids (T. B. M.).—Do not withhold water so long as growth is advancing, but under cultivation the pseudo-bulbs do not always attain the same size as these plants have when imported, and the size also varies in different seasons. Try Mr. B. S. Williams' "Orchid Growers' Manual." A new edition of the work you mention is in preparation, that will probably contain much of the information you seem to desire.

An Early Blue Plum (T. H. W., Canada).—Probably the variety to which you allude is Early Rivers, a small early Plum remarkable for its fertility. The flesh is tender, sweet, juicy, with a brisk flavour, and separates from the stone. It is ripe in July and early August. Write to the nurserymen who make a speciality of fruit trees respecting your other question.

Funkia grandiflora (T. S.).—This plant succeeds and flowers well in pots, and probably you would find those mentioned more satisfactory in this way. At a recent meeting of the Royal Horticultural Society Mr. Roupell exhibited a plant in a pot with eight fine spikes of flowers. Grown in this style it has a fine appearance. If the soil is too rich in the border it would have a tendency to develop the foliage at the expense of the flowers.

Cucumber Roots Diseased (Telegraph).—The roots are in a very bad condition and affected by the disease which has been repeatedly noticed in this Journal. An illustration with description was given on page 473, June 4th, 1885. The nodules are caused by minute worm-like creatures, which increase rapidly and induce the sudden failure and root decay of which you complain. Clear out the soil and manure, and thoroughly cleanse the house.

Loofah (W. B., Essex).—The fruit sent is that of *Luffa ægyptiaca*, a cucurbitaceous plant found in Egypt and other eastern countries. The portion sold in shops and used for bathing purposes is the vascular tissue of the fruit after the pulp has been removed. The species named *Luffa æutangula* are known to the Arabians as Liff or Louff, and the fruit is made into a pickle like the Mango, but it has a disagreeable flavour, and is not considered very wholesome.

Wintering Tea Roses in Pots (Thos. W.).—They should be placed in a cool house or other place where protection can be given them in severe weather, the pots being plunged to protect the roots from frost. Could you not give them a sheltered situation outdoors, plunging the pots in ashes over the rims, and affording mats or other protection in severe weather? A cool house is, however, the best place for them, affording water only to keep the soil moderately moist.

Distance of Vines (P. J.).—We have had Vines 3 feet apart which answered fairly well whilst the Grapes were borne on the first shoots of the cane, but after they had borne a few years we found the distance much too little from the extension of the spurs, and not being able to encourage lateral growth, which is necessary for the continued success of the Vines. We advise you not having the Vines nearer than 4 feet, and you can take two shoots from a spur or otherwise, so as not lose anything of crop through not utilising space, but the principal foliage in any case must have full exposure to light.

Amaryllis, Gesneria, Nægelia, and Tydæa (J. E.).—It would be best to keep the bulbs of Amaryllis and corms of the other plants in sand a little moist to preserve them fresh until they are required for potting, keeping them in an intermediate or cool stove, and where they will be free from drip, as when placed beneath stages they are liable to become saturated and either decay or start into growth prematurely. Our correspondent asks, "Do any of your correspondents know any way of drying Tomatoes on a small scale so as to be available for winter use? Making them into sauce so entirely destroys the flavour." We should be obliged by particulars from those having a successful method.

Williams' Bon Chrétien Pear Unfruitful (A. R.).—Either the blossom is destroyed by frost or it is imperfect. Our trees against walls have fruited freely this year, whilst those of this particular variety have not borne any fruit on pyramids worth mentioning. This we attribute to the difference in respect of immunity from frost. If the bloom does not set through damage from frost we can only suggest protection; indeed a crop can hardly be relied on without means of protecting the blossom in case of frosts occurring at the time of setting. The blossom may fail to set from imperfection, which usually arises from a deficiency of aliment in the previous season, mulching and watering not being attended to in dry weather so as to insure the maturation of the buds. More liberal treatment with protection of the blossom would probably result in a crop.

Lifting Young Vines (W. T.).—It is a great mistake to have Muscats planted alternately with Black Hamburgs in the same house, as justice cannot be done to either, and we do not think you will mend matters by shifting the Muscats to one end, having Black Hamburgs at the other, as it is scarcely possible to maintain the needful temperature for Muscats by less ventilation at that end of the structure. What you require is a partition so as to make the house into two, having Muscats in one and the Black Hamburgs in the other, and even then you will need to have the pipes arranged so as to heat each house separately. It is little use attempting to grow Muscats if you cannot command a higher temperature than 50° when they are in flower. Instead of lifting the Vines we should take up fresh canes from the Black Hamburgs and train them so as to supplant the Muscats, or you might graft the Muscats with varieties requiring similar treatment to the Black Hamburgs.

Pruning Neglected Vines (Walbert).—In order to insure a crop of Grapes next year the shoots should be pruned to various lengths and to a plump bud in all cases on well-ripened wood. If the spur shoots are cut hard back there is little prospect of a crop of fruit, and there may not be a satisfactory break. It is much better to act cautiously in cases of this kind, as the hard pruning is only calculated to induce further growth, and scarcely that from pruning hard back to two-year-old dormant buds. We should prune or cut away some of the shoots where most crowded and least promising, and so shorten the other as to provide for an even spread of growth and crop. If the Vines are desired on the spur system a fresh cane may be taken up from the base of the rafter, and as this advances the old spurs or growths on the old rod may be cut away to allow of its extension, and ultimately be removed. In that way the rods may be renewed without loss of crop.

Asphalt (J. M.).—The small dust should be rejected, also the larger particles, but under ordinary circumstances it is only necessary to pass the ashes through the screen, using the screened part, the rougher portions being employed for the foundation of the road or pathway. The best material is the ash from large boiler furnaces, as it is harder burned than that of house grates, and passed through a half-inch screen it is first rate. The clinkers broken if requisite will be suitable for forming the necessary bed, which should have the same form as the intended surface. Soft stone is no good, as it will not wear, but it may be used for levelling before laying the asphalt. Leave a hole in the centre of the ashes, into which pour boiling coal tar, mix well together, and when as stiff as mortar lay it down 3 inches thick on a dry and previously well levelled surface. It may be sprinkled with fine spar or granite or sand, distributing just enough to prevent the boots sticking to it, and when sufficiently firm pass a roller over it. All the materials as well as the surface on which the asphalt is placed should be perfectly dry. Cold tar will not answer, it must be boiling hot.

Sowing Ranunculus Seed (H. J. P.).—Sow the seed in February in boxes about 18 inches long by 11 inches wide and 4 inches deep, full of loamy soil, and the surface level. Let the seeds be about the eighth of an inch apart, cover them thinly with soil, and water with a fine rose, placing the boxes in a cold frame. The plants usually make their appearance in about a month. Afford air day and night except in the severest weather, then cover with mats. Place them outdoors about the second week in May, and water daily until the leaves wither, let the soil become quite dry, and in the middle of July lift and preserve the roots in bags until February, and then plant them as the general stock. In the following June they will flower. The roots should be planted in drills about 2 inches deep, placing a little sand at the bottom, and after planting just cover the crowns with sand. The rows should be 5 inches apart and the roots 4 inches asunder. The beds may be 4 feet wide, with 18-inch-wide alleys between. The ground requires to be in good heart and well worked. Your proposed preparation of the ground ought to answer. The commercial value may be 10s. per 1000 roots, but much depends upon the strain and other circumstances.

Spearmint and Peppermint (M. S.).—Spearmint, or Green-mint, is *Mentha viridis*, a native of Britain, in marshy places. The plant has a strong, aromatic odour, with a warm and slightly bitter taste, which is less pungent but more agreeable than that of peppermint. The properties of the plant depend on a volatile oil, obtained by distillation. Oil of Spearmint is pale yellow or greenish when fresh, but becomes darker with age, and ultimately of a mahogany colour; it is used for the same purposes as oil of Peppermint. Its specific gravity is 0.975, and its boiling point 320°. Peppermint (*M. piperita*) is also a native of Britain. The plant has a warm, pungent, and camphorous taste, leaving a remarkably cold sensation in the mouth. Its odour is very strong, balsamic, and penetrating, particularly when touched, and which it does not lose, even in drying. Peppermint is stimulant and aromatic, and is good against nausea and flatulence. Its properties are owing to the presence of a large quantity of volatile oil which it contains, and is obtained by distillation. Oil of Peppermint is greenish-yellow, and has a strong aromatic odour, with a warm, camphorous, and very pungent taste. Its specific gravity is 0.920, and its boiling point 365°. It is often adulterated with alcohol, and even with oil of turpentine. Combined with alcohol it forms essence of Peppermint, and it is used medicinally as a carminative and stimulant, as well as in confectionary for flavouring bonbons. Peppermint water, obtained by distillation, is very much employed in tonic, cordial, and anti-spasmodic drinks.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*No Name*)—1, Jefferson; 2, Washington; 3, Pond's Seedling. Pear unknown. (*E. Wallis*).—White Magnum Bonum. (*M. A.*)—Pear not known. It ought to be gathered before it is ripe and allowed to mature in the fruit room. (*G. L. Court*).—Beurré d'Amanlis.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes, slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*W. C. & Sons*).—The specimen being loosely packed was damaged and dried when it reached us, but it is probably *Matricaria inodora plena*, a hardy plant of easy culture. (*W. C. Havant*).—The succulent plant is *Stapelia variegata*. The *Cypripedium* is a good variety of *C. insigne*. (*G. R.*)—3, *Gymnogramma chrysophylla*; 5, *Selaginella Martensi variegata*. The other specimens are insufficient for naming, and a sample of the wood and foliage should have been sent with the Plum. (*T. S.*)—We will endeavour to give you the name required next week. (*R. B. S.*)—1, *Xylophylla falcata*; 2, *Veronica Andersoni*; 3, *Osmunda gracilis*; 4, *Doodia aspera*. (*R. W.*)—*Lobelia syphilitica*.

COVENT GARDEN MARKET.—OCTOBER 3RD.

OUR market is now overstocked with Peaches, with difficulty clearing at low prices. Cobs down in price.

WHEAT SOWING.

AFTER a season remarkable for fluctuations of weather, and consequently with more than the ordinary difficulties which beset the farmers' calling, we have come to the end of the agricultural year and are face to face with the beginning of another. No cessation of work, no rest, in the common reception of the term, must there be, for so late was the harvest that the carting of the last load of corn had to be followed at once by a prompt preparation of the land for sowing green crops and winter corn, among which Wheat still holds the leading place.

Pressure of business prevented us seeing the finish of harvest on one of our off-hand farms. When we went there a few days subsequently the first sight we beheld was a Barley stack near the road with a couple of green Oak branches thrust into the top, to proclaim to all and sundry that the harvest was ended and that it was the last stack built on that farm. Turning from that not unwelcome sight we found ploughs and manure carts in full swing in preparation for autumn cropping. "Well done!" said we to the bailiff, "make the most of the fine weather for carting, ploughing, and sowing, and leave all corn-threshing alone till the winter corn is in." The ploughs were at work upon an old Clover layer upon which sheep had been folded, so that it was thoroughly manured in readiness for Wheat. Other land which had been a bastard fallow, and then sown with White Mustard, had already had that valuable green crop ploughed in and was quite ready for sowing. Two fields from which winter Beans had just been cleared were being dressed with pig manure to be ploughed in for Wheat, and this comprised all the Wheat land for next season on that farm. But there are some ninety acres adjoining this farm falling in hand from a tenant this Michaelmas, upon which there is a full proportion of bare fallow under the old four-course shift, and this fallow land will be sown with Wheat immediately after Michaelmas. We know full well how low in fertility the tenants' fallows are, and shall have to resort to an autumn and spring dressing of chemical manure for the Wheat in order to insure a profitable crop. The formula is in autumn half cwt. nitrate of soda, quarter cwt. steamed bone flour, quarter cwt. mineral superphosphate. In spring half cwt. muriate of potash, $1\frac{1}{2}$ cwt. nitrate of soda, $1\frac{1}{4}$ cwt. steamed bone flour, half cwt. mineral superphosphate. The manures are procured separately from a reliable source and mixed at the farm under close supervision.

All due care being taken to keep the land clean, free from superfluous water, and well stored with fertility, the next point of equal importance is to select and sow good seed. Glad indeed are we to say we have no difficulty now about the seed, for we have got rid of all inferior sorts from the whole of our farms, and the only question is which sort is best for all seasons. The sorts to which we give preference now are Defiance and Squarehead. Of these Defiance has much the finest grain this year, but Squarehead has so many high qualities that we feel bound to use some, and we shall sow about 200 acres of it. Of Defiance the published character is as follows:—"This very popular red Wheat is distinct from and far superior to any other variety on account of its productiveness and grand quality. The ear is of large size and remarkably thick set, while the grain is wonderfully plump and eagerly sought after by millers. It has also the great advantage of being very free from rust, and succeeds well where other red Wheats fail." There! is not that a good character? We certainly are able to say after growing it for two years that it answers

well to most of the description. But what are we to say to the more recent introduction termed *Sulvator* by one firm and *Mountain White Wheat* by another? It is a white bearded Wheat, which, like the *Beardless Barley*, loses its beard as the corn ripens, and is said to yield 88 bushels an acre, and the straw grows 7 feet high. We have seen a sample of this wonderful introduction, and it was so superior to ordinary Wheat that we have ordered some of it for trial, and if it proves at all equal to the description it will be used on our heavy land farms. All is not gold that glitters, but we always give a fair trial to any novelty of promise, for we hold that it answers to grow the best sorts and only the best.

WORK ON THE HOME FARM.

Harvest work is now practically over, the only crop out as we write being some spring Beans, which are still green, but the pods are full and the crop one of remarkable abundance, with such strong growth that the sheaves have the appearance of huge faggots. Late sown Peas proved a troublesome crop, ripening very slowly owing to the abnormal growth induced by a wet season. All have now been carted in fair order. As the last were still somewhat immature we had them put into long narrow stacks through which the air can circulate and dry the Peas thoroughly. The latest fields of Barley had the corn in best order when carted, for the recent spell of fine bright weather has indeed proved a blessing to farmers generally. Much caution will be necessary in threshing corn this season, as so much has been carted without being quite dry and hard.

Of work pressing for immediate attention ploughing land for green crop and winter corn is the most important. Those fortunate farmers having steam tackle may be able to get some land clean for spring crops also, but that is just a question of fine weather. First of all we will sow Rye and Winter Tares, then come winter Beans, Oats, and Wheat. On heavy land especially we cannot push on Wheat-sowing too fast for we like a full strong plant before severe winter weather sets in. Our best crops of Wheat this year on heavy land was from seed sown in September, but Wheat-sowing in September this year was impossible, and so we must just do our best in October. We have still got the mowing of second crop Clover and Sainfoin to do, but we cannot hope to save any good Clover seed now, and must try and turn it to account for forage. Much Clover has been folded by sheep, but there has been such a superabundance of green food that it was impossible to use the whole of it in that way. Sheep now find a brisk sale at high prices, and the full crop of roots certainly justifies the proceeding, but let farmers look well to a due provision of green crops for spring use also.

AGRICULTURAL LECTURES.—The annual course of lectures on agriculture will be given at the City of London College, Moorfields, on Tuesday evenings, at 7 P.M., beginning on October 2nd, by Mr. Bernard Dyer, B.Sc., F.C.S., F.L.S., Consulting Chemist to the Essex, Leicester, and Devon Agricultural Societies. The lectures will treat of soils, plant life, manures, tillage operations, live stock, dairying, food, &c. The course will be in connection with the Government Science and Art Department, and will end in May. In addition to the College and other prizes, the Sadlers' Guild offer, as in former years, a prize of £5 5s. to the student who passes the best examination in chemistry and agriculture.

REMARKS.

23rd.—Misty morning, cloudy day, bright evening and night.
 24th.—Sight shows early and about midday, otherwise fine and bright.
 25th.—Wet morning, dull afternoon and evening.
 26th.—Fine and bright.
 27th.—Cloudless morning, fine afternoon, with solar halo 4.30 to 5 P.M.
 28th.—Misty morning, dull drizzly day, with showers in the afternoon.
 29th.—Dull morning, fine day; sudden heavy rain at 9 P.M., lasting till after midnight.
 A variable week, but with much more fine and bright weather than would be inferred from the number of wet days and total rainfall. Temperature about 3° above the average.—G. J. SYMONS.

FRUIT CONFERENCES.

WHATEVER divergence of opinion may have existed on the action of the Royal Horticultural Society in the conduct of its affairs, there can be nothing but unanimity in respect to the decision arrived at in having periodical conferences at Chiswick on subjects of importance to the general community. The greatest success ever achieved by the Society was in holding the Apple Congress in the renowned Gardens a few years ago, the measure of that success being determined by the demand for the "Report" that was subsequently published. The Pear Congress was interesting and instructive, but essentially less useful, but only because of the intrinsic difference between the two kinds of fruits, one being largely a luxury for the palate, the other an important article of food.

The coming Conference will be in the nature of a combination—a combination of excellencies it ought to be, seeing that the collections of fruits staged will be selections, and thus representing the best varieties in cultivation in the best manner the season allows. From the nature of the conditions the exhibition cannot be expected to approach in magnitude its two predecessors, but it should excel them greatly in average of merit. Than some of the specimens that were staged when all varieties were invited, we cannot expect to see finer next week, and possibly, having regard to the inclement summer, the best may not equal the premier dishes of former years; but an enormous quantity of inferior fruit was of necessity sent to those gatherings (and rightly sent considering their nature) that ought to be absent from the collections of the present year.

The concentration of effort on the subject of fruit production and disposal cannot fail to be of great value, not to a section but to the general community. The isolated action of individuals no longer suffices in these competition-of-the-world days to keep us abreast of the times, and competent to meet the best products of other lands, raised and placed in our markets under a system of combination of resources. The old time-worn habit of personal and trade jealousies must no longer stand in the way of general advancement, but all must combine in contributing to a common fund of knowledge for a common object—developing the resources of the soil, and placing before consumers better supplies of life necessities than they can obtain elsewhere. That this can be done in the case of many of our hardy fruits is certain, and we have no doubt will be done eventually, but the object cannot be accomplished in a season.

The great desideratum is to ascertain right lines of procedure, which, if followed perseveringly and systematically, can only have one result, and that a good one. A community of effort, though seemingly antagonistic to personal endeavour, is not really so. There will be the same scope for wholesome individual rivalry as before, and this will be stimulated rather than suppressed by the consciousness that each knows the other's opportunities for acquiring information on matters in which all are interested. It is the aptitude of turning knowledge to account in which differences will and must be found; but the striving for excellence will be all the same stimulated, and the aggregate advantages accruing from informal, yet effective, co-operation cannot fail to be both seen and felt as time rolls on. Harmony of action amongst individuals working in

the same cause for the same end, combined with personal rivalry are the lines on which to work if we would attain to a position of supremacy as producers of life necessities for a teeming and ever-increasing population.

To accomplish this we even welcome rivalry, friendly and pleasant, in conferences, and this we have. The Crystal Palace meetings have done much good, and those at Chiswick must do much more, and the results of both will leave us the richer, while neither of the agencies can be weakened by the efforts made in work that is in every way so commendable.

The days of shows—bare shows—something to see and little more—have ceased to be satisfying, and it was a happy idea to associate with them meetings for the reading of essays and discussions thereon, and the earnestness, not to say the enthusiasm, displayed at the first of these gatherings at Sydenham showed conclusively what is wanted by the horticultural community; and having regard to the subjects to be advanced at Chiswick next week and the character of the authors an equal success may be hoped for in the gardens of the Royal Horticultural Society.

PREPARING FOR WINTER.

CULTIVATORS of gardens cannot have much to say in favour of 1888. As a rule it has been unfavourable for all. The spring was very late and backward, and there was no real summer. The autumn since about the beginning of September has been better and vegetation has been matured considerably, but a severe winter would soon show that much of it was far from being in sound condition, and it will require careful preparation to guard against blanks and failures. Holly and other berries are very plentiful. Some say these indicate a severe winter, but I do not place any reliance in the assertion, as I have frequently noticed the indication is not verified: but on the morning of October 2nd we had sufficient frost to blacken the leaves of Dahlias, Vegetable Marrows, and Kidney Beans, and I cannot disregard what this denotes. I can see plainly it will be prudent to prepare for winter in good time, and October is the month when this ought to be done.

Being a kitchen gardener, and knowing how important it is to have a good supply of vegetables during the winter, I give these attention first. Many have mistaken ideas about weeds in the kitchen garden. They are of opinion if the crops are well surrounded with them in autumn and winter that they will prevent the frost doing harm, but they are the worst of all shelters; indeed, they are injurious, as they make the plants very tender. The best way of guarding against the frost and wet doing harm is to expose the plants fully in autumn; then they are hardened and matured, and it is astonishing how much they will stand after that.

Dead leaves are no advantage about the plants. They retain the moisture around the stems, and wet plants always suffer more from frost than when they are caught quite dry. I therefore recommend that the dead leaves be removed from everything. Some may say, Broccoli and Brussels Sprouts, Curly Greens, and Savoys are hardy enough, and in their case it does not matter, but it is as important that the dead leaves be cleared from these as from anything else.

Lettuces and Endive should be lifted and stored in frames. If the plants are small give them some good soil to grow in; if large, and not likely to grow much more, plant them in sand or fine ashes, as they will not suffer from damp so much in these as in soil. Store Onions in a dry room or shed. Take up Beetroot, cut the leaves off about 4 inches from the crown, and store under cover amongst sand or ashes. The material should not be too damp, as it may generate decay, and if too dry it is apt to make the roots shrivel. Carrots may be stored in the same way, but it is only those that are fully grown, or the main crop, that should be stored. Late-sown ones that have not gained full size must not be taken up,

but left to be drawn as required. Store a quantity of bracken, straw, or some kind of covering material, to have it ready for covering Celery and other crops as soon as frost comes, but do not on any account begin protecting until then. We have frequently saved the crowns of Parsnips and Salsafy by spreading a quantity of leaves over the ground in which they were growing, and this also protected them from frost, so that there was no difficulty in digging up the roots as the ground was not hard.

We are now housing our Chrysanthemums. The last of them will probably be in before these notes are in print. As extra attention has been given them this year, the buds are large and promising, and we were afraid they might be injured by frost. This must be avoided, and the best place for all plants of value now is in the greenhouse, a Peach house, or vinery from which the fruit has been gathered. Do not shut them up. Let them have air day and night so long as there is no severe frost. They will then be in good order to stand the winter so far as they last into it. Begonias, Primulas, Cinerarias, and all tender greenhouse plants that have been in frames during the autumn should now be moved into a house. This applies more particularly to plants in cold frames. Where the frames are heated the plants may remain. Be sure that all the dead leaves and superfluous growths are removed, and it is equally important that the pots be washed. It is remarkable how easily a plant in a clean pot is kept in health as compared with one covered with green slime and dirt. I attach the utmost importance to having clean pots in winter; indeed it is one of the secrets of successful wintering of plants. In applying fire heat to plants in winter, a mistake is often made when it is said "the nights are getting very cold; I fear our plants will suffer," and heat is forthwith applied. This may suit tropical plants, not greenhouse and bedding plants, and it does more harm than good, as it makes them very tender before the winter has really set in. If we have a long period of wet we light the fires sometimes to expel the damp, but apart from this we avoid firing as much as possible until it is needed to keep frost out. After the new year this is not so important, as if plants do begin to grow then they can generally keep it up, but when prematurely excited in November the tender growths are almost sure to dwindle and die before March.

A great distinction should be made between plants that are only stored for the winter and those that are grown to be useful at that season. The want of sufficient light is the cause of many plants becoming unhealthy or dying altogether in winter, and all of any value should be so arranged that they may receive it, and any sunshine that may appear as well. Careful ventilation is another operation which adds much to their health and safety. If the houses or pits are at all air-tight keep them closed up on wet days, and open the ventilators when the atmosphere is inclined to be dry outside. As a rule front ventilators should not be much used in winter, but as the damp air ascends let it escape at the top. After a few days or weeks of wet the pipes or flues should be heated when air is given.

We are now coming to the time which is admitted to be the worst of all for keeping Grapes. If they can be safely taken through the latter part of October and November they will not be very troublesome afterwards, and to accomplish this keep the surface of the inside borders rather dry, remove every leaf as soon as it decays, clip decaying berries out as fast as they appear, and work the fires and ventilators so as to keep the atmosphere always very dry. If these details are carried out, and they are simple enough, I will guarantee the Grapes to winter well. Too much water at the root is a dangerous condition to plant life in winter. To those in a strong heat it may not be very injurious, but all plants in cool houses will suffer severely. We have some large plants of various kinds in a house where we cannot apply fire heat in winter, and it is astonishing how healthy these remain by a close observance of the rule of keeping the soil at the roots somewhat dry from October until March. We all know how much vegetation in the open suffers in winter in badly drained land, and this applies so forcibly

to plants in pots that the drainage of every one ought to be in good order before winter.—A KITCHEN GARDENER.

A LIBEL ON NURSERYMEN.

A GREAT deal of rhodomontade on fruit-growing appears from time to time in the daily papers that is not worth notice in these columns, but a paragraph, as stupid as it is scurrilous, was published last week that cannot be passed in silence. It is signed by the "Secretary" of a so-called "National Fruit Growers' League," and is as follows:—"Why is it that tons and tons of fruit are left to rot in the orchards where they fall from the trees? Simply because they consist of useless and unsaleable kinds. The nurseryman's stock in ninety-nine cases out of a hundred consists of these worthless trees. In this country at the present time there are millions of these useless trees in existence—what is to become of them? They are only fit to be burnt. In this sense it is a pity that at our conferences nine out of every ten committeemen are nurserymen having a pecuniary interest in the disposal of these worthless trees."

From the first two sentences we do not dissent, but the allegation that "the nurseryman's stock in ninety-nine cases out of a hundred consists of these worthless trees" is a gross and palpable untruth. The trees in nurseries are as unlike the decrepit and useless standards in old and neglected orchards as it is possible for trees to be; and to imply that nurserymen procure grafts from such worthless trees and varieties for propagating and distributing among their customers, betrays an amount of ignorance on the part of the writer of the paragraph in question that we did not suppose existed in these days, while it attributes to the men assailed positive foolishness, amounting even to trade suicide. Does not the assailant know that worthless varieties of trees would, if raised, occupy as much of the precious space in nurseries as the most superior, while the latter have a ready sale, doing credit to the vendors, and bringing more business through giving satisfaction to purchasers? Nurserymen have to keep many varieties of fruits in stock for garden culture, and the completion of collections that many persons derive pleasure in forming; but these are a very small minority, the great majority, amounting to ninety-nine out of a hundred, consisting of the very best and most profitable varieties in cultivation, these being in the greatest demand, and their raisers have the greatest pleasure in supplying them.

No one understanding what he sees can visit the establishments of the leading raisers of fruit trees without recognising the cleanness and general excellence of the stock, and it is easy to ascertain that the most useful varieties are produced in the greatest numbers; and no persons know better than those growers, and few as well, the best varieties to choose for different purposes and positions. It is a pity a respectable newspaper should be deluded into publishing such trash as is contained in the above paragraph, the closing sentences of which are positively insulting to as honourable a body of men as can be found in any other craft or calling. It is not for this "Secretary," whoever he may be, to malign men whose position and antecedents are at least as good and unsullied as his own; and to suggest they have got themselves appointed on committees to enable them to sell "worthless" trees is indeed pitiable, while to assert that "nine out of ten" of conference committeemen "are nurserymen" is entirely and absolutely false. There are only a sufficient number to render the committees fairly representative, and there are no more useful members than those alluded to. If the Secretary of the "League" continue to indulge in such reckless assertions and unworthy insinuations as those cited he can scarcely fail to speedily bring it into disrepute.

TRITOMAS.

THE Tritomas are unrivalled among hardy perennials during the autumn months. They are the most valued when the cold nights and nipping frosts have blackened and disfigured the Dahlias; and when the usual bedding plants have once more completed their task then it is that these "Red-hot Pokers," "Flame Flowers," or "Torch Plants," as they are often called, are seen to greater advantage than ever. There is nothing fastidious about these plants beyond some requiring slight protection in winter, and this may readily be given in the shape of a mulching of dry litter or bracken; and should they occupy positions much exposed then I would further advocate making them protect themselves by tying their leaves up in the shape of a sugar-loaf or cone late in autumn after flowering is complete. This may easily be accomplished by gathering the leaves rather closely together, and should they be at all massive a little dry straw may be placed between the foliage to prevent decaying, tying the whole up in a pyramid with three or

more stakes, as occasion may require, then with a handful of straw form a cup on the top, and all is complete. This may seem considerable trouble for a plant which is called hardy, and which is hardly beyond doubt so far as actual frost is concerned, but which at the same time cannot endure alternately frost, thaw, rain, and snow in a period of twenty-four hours. The Tritomas suffer most perhaps in common with Yuccas, Pampas Grass, and a few others from snow settling in their hearts, and from which they seldom recover. The Yuccas are broken down and thus permanently disfigured, but which can be avoided by adopting the plan I have alluded to; for all will readily admit that it is easier to thus protect fine specimens which do exist rather than let them take their chance of being either killed outright or, it may be, rendered unsightly objects for the greater part of the ensuing year. Nothing is more discouraging or disappointing as the spring time dawns than to discover one by one how this or that plant has suffered during the winter just past.

The positions most suited to these plants are the large border, the shrubbery in good open positions, not crammed between huge and ungainly specimens. For conspicuous places on the large rockery, or in bold masses or groups on the lawn, they are grand and effective, and are always admired. An excellent effect may be produced by forming an irregular clump on the lawn, say of twenty or thirty plants, raised a couple or 3 feet in the centre, and sloping to the sides. Dotting plants here and there may be very well in many cases, but nothing can pourtray the importance of this handsome genus of plants like planting in bold picturesque masses. With exactly the same results might this be extended even in our London parks and gardens, that the public may the more fully appreciate one of our best town plants.

But now a word as to planting time. After some experience with these plants, I consider that March and April are the best months for planting Tritomas. They may, however, be planted in autumn very successfully on warm, well-drained soils, but not always so on cold or clayey soils. If from various causes they must be planted in autumn, it is most important that the foliage should be left entire, and not cropped off to within a foot of the ground. In wet seasons, or when snowstorms are abundant, this cropping off the leaves, which is done sometimes for mistaken tidiness, often ends fatally, and should therefore be avoided.

The Tritomas have of late years increased in importance by the addition of new varieties, some of which assist in extending an already lengthened period of bloom, and at the present time by selecting the best of new and old varieties their richly coloured spikes may be had almost without interruption from early in August till the end of November. The best known and most widely distributed are the varieties of *T. Uvaria* itself, valuable and free-flowering. This is usually 3½ feet high, producing spikes of orange and scarlet flowers, which begin to expand in August and continue to October. The other forms of this species are *grandiflora*, a bold habited plant with crimson and orange-coloured spikes; *grandis* has a good deal of the last named about it. In general aspect and colour the two are not requisite in one collection, though both are excellent individually. *Glaucescens*, very distinct foliage and flower, the latter being of a bright orange scarlet and very effective, toning to deep orange with age. The last of this group is *nobilis*, a well named form, fully 7 feet high, producing a succession of reddish orange spikes from September to November, and in open seasons even later. Of other good and distinct forms *T. Macowani* is deserving special mention. It is much dwarfer than those already named, and rarely exceeds 18 inches high. It is not so robust as the majority, and is remarkable for its charming light golden orange red tinted spikes of flowers. This is just now (October 3rd) passing out of flower, and is well suited for the rockery or the border. A distinct species is *T. Leichtlini*, a September flowerer, which bears grand spikes of yellow flowers. This is most handsome and should be grown by all. *Mutabilis* is among the earliest of all, and has completed flowering nearly a fortnight; its spikes of saffron yellow changing to orange and slightly tinted with red are very pleasing. It grows from 3 feet to 4 feet high and is a very handsome plant. The last I shall now name is *Caulescens*. This is sometimes described in hardy plant lists as an arborescent species, which is misleading in the extreme. It may be more faithfully described as a gigantic form of *nobilis* with broad handsome glaucous recurving leaves, from which issue brilliantly coloured spikes of crimson and yellow to a height of 6 feet. I have never seen this species in a more happy condition than it is in the Birmingham Botanical Gardens. Being somewhat tender Mr. Latham, the able curator, has thoughtfully placed it at the foot of the wall of the new conservatories, where it enjoys full exposure to the sun in a border duly prepared for them. It is not suited to a heavy soil or damp low-lying position, but the reverse.

All the species and forms are readily increased by division and

also by seeds, which in most kinds germinate with remarkable freedom. I have this season potted several thousand plants from seed sown about eight months ago. These are now ready for planting in the open ground. I mention these facts to illustrate how readily a stock may be obtained for purposes of naturalisation either in the woodland or the arboretum.—J. H. E.

POTTING SHEDS.

WHEN visiting the gardens of L. Gueret, Esq., of Castleford, Chepstow, recently we greatly admired the potting house; for a house it is, not a shed such as is usually found in gardens. A new range of glass houses were erected in these gardens some three years since, which do great credit to the builders, Messrs. Boulton & Paul of Norwich, the house referred to being almost a continuation of the stove, forcing house, &c., and differs from these only in proportion to the purpose for which it is required, being efficiently heated and well fitted with every convenience necessary, such as cupboards, writing desk, &c. Nor is this all, as was pointed out by Mr. W. Iggliden in this Journal some years ago. These potting houses can be used in various ways—as an orchard or Tomato house, or, as in the case in question, a vinery, for we noticed a Vine of Foster's Seedling making its way up the roof of the house and bearing a few creditable bunches of fruit. Mr. Geuret evidently saw all this and probably much more when having these houses erected, for when there is a house of this kind close to the plant houses it must be clear to all that not only can much more work be done in a given time, but it can also be much better done, to say nothing of the additional comfort to those employed. How often do we find in gardens elaborately built glass structures with perhaps every accommodation for growing the plants, while the potting shed, mostly very badly lighted, is some distance away.

Owners of gardens are not always to blame for this sort of thing. We know of instances where it has been entirely the fault of the gardener; and, again, we could tell of cases where by a small outlay the want has been adequately supplied, and in return a profitable crop taken from the roof. We have often been obliged in early spring to do much of the potting in houses where the plants were growing. This may still be advisable in certain cases even where such a house as described above exists, but it is often a very great nuisance, especially on bright days, for it is not easy to keep the atmosphere in a condition to suit both plants and men, besides which the door has often to be incessantly opened and shut, which I need not say, when it opens into the cold air, is very objectionable. In cases (and there may be some) where the potting house or shed is of necessity disconnected with the plant houses, the glass potting house is of double advantage, as plants which have been repotted may be allowed to remain where they are for a few days until there is a favourable opportunity for removing them, I mean when the external air is exceptionally cold.—W. JENKINS.

ROSES AT THE NATIONAL ROSE SOCIETY'S METROPOLITAN EXHIBITIONS.

HAVING now before me the necessary data for the last three National Shows, I am able in the present analysis to give the average results for the whole three years, instead of, as before, the positions taken by the different varieties at each show separately. A three-years average is of course a very short one, but it is the best as yet at my disposal. Had any one of the last three Rose seasons been an early one the tables here given would have been in every way more satisfactory than they now are; but unfortunately each of these three summers has been unusually backward, so that the earlier flowering kinds become unduly favoured, whereas those coming into bloom late occupy lower positions than they are entitled to. That these adverse influences have not, however, seriously affected the places accorded to the leading varieties is, I think, shown by the fact that when the results obtained at the Society's two Exhibitions this year—one held on the 7th and the other on the 20th of July—were compared, there was found to be but little difference between them. In fact, out of the twenty-four Hybrid Perpetuals most frequently shown at the Crystal Palace and Darlington respectively, only E. Y. Teas, Prince C. de Rohan, Xavier Olibo, Camille Bernardin, and Heinrich Schultheis are absent from both lists. With the exception of those Roses sent out since 1882, the positions of the varieties included in the accompanying tables, are dependent upon the average number of times they were shown in the prize stands at the last three metropolitan Exhibitions of the National Rose Society. The 1883 Roses are placed according to their averages for the last two Shows only, while for the still newer kinds the number of times they were staged at this year's Exhibition is alone taken into

account. The total number of Roses tabulated for the purposes of this analysis is altogether 5420—viz.,

	HYBRID PERPETUALS.	TEA AND NOISETTES.
1886	1038	509
1887	1130	642
1888	1247	854
	3415	2005

The past summer was the most backward of the three seasons. Moreover, instead of the weather being hot and dry previous to the metropolitan exhibitions being held, as was the case in 1886 and 1887, the end of June and early part of July this year proved exceptionally wet and chilly; consequently, although when the annual lists are examined separately most of the principal varieties come out in nearly the same positions each year, yet, as might be expected, there are a certain number of important exceptions. By comparing the average positions of the different Roses at the two previous exhibi-

HYBRID PERPETUALS.

Position in Present Analysis.	Average Number of Times Shown in the Three Years.	Number of Times Shown in 1888.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.

39	6.0	7	Magna Charta	1876	W. Paul & Son	Bright pink carmine.
39	6.0	5	Rosieriste Jacobs	1880	Ducher	Dark velvety red.
40	5.7	5	Alfred Dumesnil	1879	Margottin fils	Light crimson rose.
41	5.3	13	Auguste Rigotard	1871	Schwartz	Cherry red.

TEA AND NOISETTES.

Position in Present Analysis.	Average Number of Times Shown in the Three Years.	Number of Times Shown in 1888.	Name.	Date of Introduction.	Raiser's or Introducer's Name.	Colour.
1	37.8	50	Catherine Mermet	1869	J. B. Guillot fils. ...	Light rosy flesh.
2	37.3	34	Maréchal Niel	1864	Pradel	Deep golden yellow.
3	35.7	46	Innocente Pirola	1878	Madame Ducher ...	White, slightly shaded.
4	33.3	57	Marie Van Houtte	1871	Ducher	Yellowish white, tinted rose.
5	31.0	43	Souvenir d'un Ami	1846	Belot-Defougère ...	Pale rose.
6	30.7	37	Souvenir d'Elise Vardon	1854	Marest	Yellowish rosy cream.
7	30.3	24	Caroline Kuster	1872	Pernet	Lemon yellow.
8	28.9	24	Comtesse de Nadaillac	1871	J. B. Guillot fils. ...	Rosy flesh and apricot.
9	28.3	23	Niphetos	1844	Bougère	White.
10	25.3	27	Jean Ducher	1874	Madame Ducher ...	Salmon yellow, shaded peach.
11	23.5	21	Madame de Watteville	1883	Guillot	Pale lemon, pink margin.
12	21.0	51	Madame Lambard	1877	Lacharme	Salmon, shaded rose.
13	20.7	32	Honourable Edith Gifford	1882	Guillot	Blush white, tinted pale rose.
13	20.7	26	Madame Cusin	1881	Guillot fils	Violet rose.
14	19.7	23	Anna Ollivier	1872	Ducher	Pale rosy flesh, shaded buff.
15	19.0	19	The Bride	1885	May	White, tinged lemon.
16	18.0	14	Etoile de Lyon	1881	Guillot	Bright sulphur yellow.
17	17.7	34	Madame Bravy	1848	Guillot père	White, flushed pale pink.
18	15.7	31	Rubens	1859	Robert	Creamy white.
19	14.3	18	Madame Willermoz	1845	Lacharme ...	Creamy white.
20	13.7	14	Souvenir de Paul Neyron	1871	Levet	Creamy white, tinted rose.
21	11.0	2	La Boule d'Or	1860	Margottin	Golden yellow.
21	11.0	9	Princess of Wales	1882	Bennett	Pale rosy yellow.
22	10.7	23	Francisca Krüger	1879	Nabonnand	Coppery yellow, shaded rose.
23	10.0	10	Souvenir de G. Drevet	1884	Guillot	Salmon white, shaded pink.
24	9.0	12	Devoniensis	1838	Foster	Creamy white.
25	8.7	4	Madame Margottin	1866	J. B. Guillot fils. ...	Citron yellow.
26	8.3	3	Madame H. Jamain	1869	J. B. Guillot fils. ...	White, shaded yellow.
27	7.0	13	Jules Finger	1879	Madame Ducher ...	Rose, shaded silver.
28	6.7	7	Belle Lyonnaise	1869	Levet	Deep lemon.
29	6.3	9	Perle des Jardins	1874	Levet	Bright straw colour.
30	5.7	4	Madame Welche	1878	Ducher	Pale yellow, flushed pink.
31	5.3	4	Madame A. Jacquier	1879	J. B. Guillot fils. ...	Light pink, shaded yellow.

tions with those they occupied at the Crystal Palace Show this summer it will be seen approximately to what extent these climatic and other causes have affected them. Monsieur Noman, for instance, loses this year eighteen places, Marie Rady seventeen places, Duchesse de Vallombrosa sixteen, Beauty of Waltham twelve, Annie Laxton and Madame Lacharme eight, and Star of Waltham, Violette Bouyer, Le Havre, and Reynolds Hole six places. Marie Cointet, which stood at No. 10 in 1886, and as high as No. 7 last year, disappears entirely from this year's list when taken by itself. On the contrary, when tested in the same way a few sorts appear to have delighted in this cool and dripping summer. For example, Général Jacqueminot rises thirteen steps, Duke of Edinburgh (which the season for once suited admirably) and Sénateur Vaisse each twelve steps, Dupuy Jamain eleven, E. Y. Teas and Louis Van Houtte ten, and Marie Verdier seven. Duchesse de Morny, which did not find a place at all in the last analysis, judged by this year's form alone, would stand No. 17.

Out of the sixty-five varieties in the list of Hybrid Perpetuals there are only seven which are less than eight years old. These, which we may term the newer Roses, are thus placed:—First at No. 6 comes a Rose possessing perhaps more good qualities than any other member of the Hybrid Perpetual family, and that is Ulrich Brunner (1881). Immediately following it are Lady Mary Fitzwilliam and Merveille de Lyon, both brought out in 1882. The former of these is a very dwarf grower, but otherwise an extremely free flowering and high class Rose, while Merveille de Lyon is well known as the most dependable of all the white H.P.'s. Skipping over a couple of dozen older sorts we reach at No. 26 Her Majesty (1885). Next to this grand exhibition Rose, which this year owing to adverse circumstances occupies a much lower place than it is entitled to, stands Violette Bouyer (1881), a variety that the damp weather of last summer did not at all favour. At No. 28 we find Heinrich Schultheis (1882). This is likely to win its way more and more into public favour on account of its excellent habit of growth and distinct and delicate shade of colour. Pride of Waltham, which came out in 1881, is again low down in the analysis, doubtless eclipsed by its older rivals Marie Finger and Eugénie Verdier.

Turning now to the Teas and Noisettes, and treating the more

established varieties in the same way as the H.P.'s, it will be found that the past Rose season, as was the case with the Hybrid Perpetuals, proved detrimental to more kinds than it benefited. For instance, that hot-season variety La Boule d'Or, as compared with its average position in the two previous years, loses as many as fourteen places, Caroline Kuster and Etoile de Lyon nine, Comtesse de Nadaillac and Madame Margottin eight, Maréchal Niel and Niphetos five, and Belle Lyonnaise four places. On the other hand Rubens gains nine places, Marie Van Houtte eight places, and Madame Bravy seven places. Madame Lambard, the favoured Tea Rose of the year, which was set up in only ten winning stands in 1886, and in but two in 1887, appeared at the last exhibition in no fewer than fifty-one different stands.

Judging by this analysis the Teas are making far more rapid progress than the Hybrid Perpetuals. Although the list of Teas and Noisettes is only about half as long as that devoted to the H.P.'s, yet as many as seven varieties, or about one-fifth of the whole number, have come out since 1880. The 1881 Teas are represented at No. 13 by Madame Cusin, and at No. 16 by Etoile de Lyon. The past season does not appear to have suited the former, notwithstanding its sturdy petals, while Etoile de Lyon, being very full, and also thin-petalled, suffered of course considerably from the continued damp and cold weather. As compared with its position at the two previous shows it loses nine places. Of the Teas distributed in 1882 two also find places in this analysis—the Hon. Edith Gifford, a welcome addition to the Devoniensis race, at No. 13, and Bennett's Princess of Wales at No. 21. Although only sent out in 1883, that elegant butterfly-like variety, Madame de Watteville, already stands No. 11 in the analysis, and ahead of all the other newer Roses. Souvenir de Gabrielle Drevet (1884) also takes up a good position (No. 23) considering how little it is as yet known. The Bride, only sent out in 1885, is one of those few fortunate Roses which become popular at once. It is a nearly white version of the Rose which stands at the head of the list of Teas and Noisettes in the present analysis—Catherine Mermet.

The following short lists of choice varieties, which are recommended as the best for general cultivation, will, I trust be found useful, not only to those just commencing Rose-growing, but also

to those who, having mostly only inferior sorts, may wish to improve their collections. These selections are very similar to those I gave last year, but having again gone carefully through them, I do not well see how they can as yet be further improved.

HYBRID PERPETUALS.—*Light-coloured Varieties.*—Madame G. Luizet, La France, Merveille de Lyon, Captain Christy, Baroness Rothschild, Marguerite de St. Amand, and Marie Finger. *Medium Reds.*—François Michelon, Ulrich Brunner, Marquise de Castellane, Marie Verdier, Comtesse d'Oxford, Heinrich Schultheis, and Dupuy Jamain. *Reds.*—Marie Baumann, A. K. Williams, Alfred Colomb, Prince Arthur, Le Havre, E. Y. Teas, and Ferdinand de Lesseps. *Dark Varieties.*—Charles Lefebvre, Horace Vernet, Duke of Wellington, and Louis Van Houtte.

TEAS AND NOISETTES.—Innocente Pirola, Marie Van Houtte, Souvenir d'un Ami, Caroline Kuster (N.), Madame de Watteville, Madame Lambard, Hon. Edith Gifford, Anna Ollivier, Rubens, and Perle des Jardins.

HYBRID TEA.—Grace Darling.

BOURBON.—Souvenir de la Malmaison.

CLIMBING ROSES.—Belle Lyonnaise (T.), Gloire de Dijon (T.), Bouquet d'Or (N.), William Allen Richardson (N.). *Summer Flowering Varieties.*—Blairii (H.C.), Charles Lawson (H.B.), Coupe d'Hébé (H.B.), Bennett's Seedling (Ayr.) Félicité Perpetué (Evergreen), and Madame Plantier (H.N.).

In conclusion, I have to thank Mr. H. Appleby, Mr. J. Bateman, Mr. J. Burrell, Mr. T. W. Girdlestone, Mr. W. J. Jefferies, and Mr. G. Mount for their kind assistance in helping me to take down the names of the Roses at this year's exhibition.—E. M., *Berkhamsted.*

HALE'S EARLY PEACH.

I HAVE frequently written in favour of this Peach, but my remarks have not always been well received, some growers asserting it is not a good one; but after another year's experience that is not my opinion. We have a tree of it in a cool house, which invariably bears a good crop. This year we gathered the first fruits from this tree on June 20th. They were well formed, fleshy, highly coloured, and very agreeable in flavour. Another large tree in the open that grows against a wall facing the east supplied ripe fruit on August 10th; and like those under glass these were very fine Peaches. I do not hold that it is unique in flavour. It is second-rate in this respect, but in all others first-rate. It grows freely, is an abundant bearer, rarely fails to produce a full crop, and its ripening so early is greatly in its favour. I do not know a more certain Peach to bear, swell, and ripen. I have never known it fail; and in the hands of amateurs, or in positions not the most favourable for successful Peach culture, it would, I feel sure, prove invaluable. As we only require Peaches for home use in succession, we do not grow more of it than the two trees in question; but if I were growing Peaches for market, I would plant it by the dozen. A very large fruit tree nurseryman told me the other day that Hale's is now one of their leading Peaches. They have a difficulty in keeping pace with the demand. This has been by no means a first-rate year for open-air Peaches. We have scores of late fruits now that will never ripen, and our determination to give up growing very late Peaches is nearer being accomplished now than ever it was.—J. MUIR, *Margam, South Wales.*

GARDENERS' EDUCATION AND THEIR SOCIAL POSITION.

THE time is fast drawing nigh when the usual "Lectures to Young Gardeners" will probably appear in our Journal; and perhaps the usual earnest advice will be given them to improve their position by devoting themselves sedulously to the study of most of the sciences having a bearing directly or indirectly upon horticulture, and including a knowledge of Latin, French, and shorthand. This advice in itself is excellent; but the question has frequently suggested itself to me of why should a menial servant like a gardener be expected to know aught of botany, geology, chemistry, land surveying, natural phenomena, Latin, French, shorthand, &c.? Legally the gardener possessing a knowledge of all or a part of the above subjects, besides being a first-class gardener, is no more than the equal of the scullery maid or stable helper, who perhaps can only write their names in a very illegible manner. Politically, in some respects and under certain circumstances, he is the inferior of his subordinates; and socially he is very little if at all superior to either scullery maid, stable helper, or garden labourer. Why should he be? He is the paid servant of the same master or mistress; and so long as each servant performs his or her duty faithfully and well it is all the master or mistress desires or expects, and they treat each servant with equal consideration, and rightly so. Pecuniarily the gardener is very frequently the inferior of the coachman, the cook, or the butler; and yet the coachman is not expected to be a veterinary surgeon, or the cook an analytical chemist, or the butler or valet a classical scholar! Then why should gardeners become the learned men they are recommended to become? Is it because 30s. per week is too extravagant a price to pay for the qualifications of an old-fashioned gardener? Or is it to be preparatory to claiming a different recognition legally, and of elevating themselves socially? If for either or both of the latter, it is time for gardeners to bestir themselves.

It cannot be too deeply impressed upon the minds of respectable and well educated youths who seriously think of becoming gardeners, that by doing so they voluntarily become menial servants, and occupy the position of such, no matter what their education or previous social position. Probably many young men enter domestic service thinking they are entering a "profession," because gardening is so misnamed frequently, and it is equally probable that such young men would find employment quite as congenial to their tastes in directions other than domestic service if they were cognisant of all the facts, but too frequently they only realise their true position when it is too late to retrace their steps. The ranks of gardeners are much too full, and respectable and educated young men would benefit themselves and gardeners in general by selecting other occupations.

It is astonishing that people in good social position will occasionally endeavour, and sometimes succeed, to make one of their sons a gardener; this is frequently because they see only the sweets of the occupation, and are nearly, or quite, ignorant of the bitters, and of the price their sons have to pay in after life. Such parents would study their children's best interests if they made curates of them instead, for though, perhaps, their pecuniary position for the time being would not be much better than that of gardeners, yet their social position would be such as not to produce any after regrets on that score, and their chances of obtaining an average annual income of about £300 per year would be as about 18,000 to perhaps less than eighteen.

Then there are numbers of young men whose parents could not afford to give them a proper University education. Let such young men turn their attention to engineering, telegraphy, music, mechanics, chimney-sweeping, anything rather than gardening. It is painful to see the numbers of educated, bright, intelligent youths in our large private gardens and in our nurseries who are doomed to disappointment and domestic servitude, but one remove from slavery in after years; but it is the lot of nearly all of them. There is but one Chatsworth, one Trentham, one Drumlanrig, one Dalkeith; but how many thousands of gardeners are there who entered the calling of gardening hoping that they might ultimately attain such situations or something approaching them? for though they would necessarily be menial servants, yet the remuneration would bring with it some compensation for their low social status; but probably about 90 per cent. of gardeners in this country do not receive more than £80 per annum as wages, yet we have writers periodically recommending young gardeners to acquire something nearly approaching a University education, and I have just read of a training college being established at Swanley. What does all this mean? It means that masters and mistresses are to be constantly supplied with an article for 30s. that as compared with other articles of very similar manufacture is, or should be, worth 50s. in the market; but these articles are supplied at such low prices because the supply is far in excess of the demand. And head gardeners themselves are very much to blame for this. Many of them, for the sake of a few pounds premium, keep employing these young men to do work that in some cases their own handy labourers would do as well or better, and infinitely more to the comfort of the gardener. The labourer is content to remain a labourer, and he will remain in the same garden year after year and learn to take such pride in his work that he ceases to be a trouble. For every labourer that is treated in this way there is one gardener less in the market. Frequently there are four or six young gardeners being manufactured when there is only requirement for two or three. I think head gardeners would study the best interests of themselves and their fellows, both at present and in future, if they would employ fewer apprentices and so-called journeymen and employ more labourers in their immediate locality.

By all means let gardeners receive a University or college education if at the same time they are going to receive corresponding remuneration and social status; but will they receive either or both of the latter?—A. BIGHTER.

NOTES ON POTATOES.

I WAS surprised to hear how small the Potatoes were by "A Kitchen Gardener." On September 28th I finished lifting 6½ acres, and find them very good as to size. The sorts are Vicar of Laleham, White Elephant, Schoolmaster, and Beauty of Hebron. Some were diseased of Vicar of Laleham, not so many of White Elephant or Beauty of Hebron, and very few of Schoolmaster. I have another field of 8 acres to lift; the sorts are Redskin Flourball, Imperator, Reading Giant, Reading Hero, and Magnum Bonum. When they are lifted I will send you the result. I have also sixty-five sorts planted side by side, one row each, but some of them are very bad, especially the coloured sorts. The white-skin sorts seem to resist the disease best with me. I grow about 16 acres, and I always expect to get at the least ¾-ton good "ware" from every ton grown, taking one sort with the other, and we seldom have many diseased. The soil is very shallow with chalk subsoil, but the sixty-five sorts are grown on the only piece of damp soil I have, and being a wet season they have been affected more. I suffer very much from the rooks working the Potatoes. Thus I have to earth them very close on the top. They are earthed with the ridging plough and brought to a close ridge. That may be the reason they are not so very bad. I suppose that is the plan recommended by Mr. Jensen. I may add the sixty-five were not earthed nearly so high, and the work was done by hoes in the usual way.—C. OSMAN.

I THINK this year of 1888 has been the worst for Potatoes since 1879 both for disease and smallness of crop. Round here they will

not average more than a pot of 90 lbs. to the perch. The worst affected by the disease are second early sorts. White Rose and Beauty of Hebron are scarcely worth lifting, and White Elephants are much diseased. I tried Sutton's Early Market. I had 14 lbs. of seed, and have nearly 11 bushels of fine tubers, with scarcely any disease, but some have become diseased since being lifted. Sutton's Seedling, Satisfaction, and Abundance have proved good sorts, and will be largely planted next year. They have proved the three best out of eight varieties. The best way of storing Potatoes that I know of is in pits 2 feet wide, and from 1 to 3 feet deep. As I have helped to store several thousand tons in my time in that way, they should not be any wider, as when narrow they keep the wet out better.—SINGLE-HANDED.

EXHIBITION JAPANESE CHRYSANTHEMUMS.

A CORRESPONDENT sends the following list of Japanese Chrysanthemums staged in first-prize stands in open competition at twelve of the principal shows in 1887. The list has been compiled from the reports published in this Journal. The numbers after the names of the varieties indicate the number of winning stands in which they were included. The shows were the Crystal Palace, Kingston-on-Thames, the National Chrysanthemum Society, Portsmouth, Brixton, Lewisham, Ascot, Sheffield, Birmingham, Hull, Pontefract, and Liverpool. The exhibitors were Messrs. C. Gibson; Packman, Molyneux, Mursell, Shoesmith, Page, Parker, Mease, Daniels, and Cox.

The varieties are as follows:—Fair Maid of Guernsey, 12; Madame Clemence Audiguier, Triomphe de la Rue des Châlets, and Meg Merrilies, 11; Mdle. Lacroix and Jeanne Délaux, 10; Criterion, Boule d'Or, and Madame J. Laing, 9; Thunberg, Belle Paule, and Val d'Andorre, 8; Japonais, 7; L'Adorable, Ralph Brocklebank, and Golden Dragon, 6; Maiden's Blush, Comte de Germiny, Marguerite Marrouch, Baronne de Prailly, and Soleil Levant, 5; M. Tarin, Elaine, Mdle. Blanche Pigny, M. Astorg, Mr. J. Laing, M. Freeman, Duchess of Albany, and M. Burnet, 4; Fernand Feral, M. Délaux, Grandiflorum, Mdle. Moulis, La Triomphante, Martha Harding, and Carew Underwood, 3; Hiver Fleuri, M. Ardene, Album plenum, Peter the Great, and Edwin Molyneux, 2; William Holmes, Agréments de la Nature, Dormillion, Mdle. B. Rendatler, Red Gauntlet, Avalanche, Mrs. Townsend, Madame Feral, Snowstorm, Mrs. W. Harris, Roi des Japonais, Gloriosum, Balmoreau, Source Japonais, Stanstead White, La Sceptre Toulousain, and Annie Clark, 1 each.

CHRYSANTHEMUMS AND THE FROST.

CULTIVATORS of the above will have reason to remember the morning of Wednesday, October 3rd. From 10° to 13° of frost were registered in this district after a heavy rain on Tuesday. Few had the whole of their collections inside, and in some places not a plant was housed. I have seen several which are completely ruined. Where the buds are well advanced not so much damage will be experienced, but in all cases where they are small and just taken, when they are in a very tender stage, on close examination will be found to be of little use. This is very disappointing after all the trouble that has been bestowed on them, and we are within a few weeks of their flowering season, when all would be anxiously looking forward for the reward of their labour. Up to the first week in October I have always considered them safe outside, and have never before known any very serious damage done to them.—EDWIN BECKETT, Aldenham House Gardens, Elstree.

NATIONAL CHRYSANTHEMUM SOCIETY.

A GENERAL meeting of members of this Society will be held on Monday evening, October 15th, 1888, at "Anderton's Hotel," Fleet Street, City; the chair to be taken by E. Sanderson, Esq., the President, at seven o'clock precisely. This meeting is convened in accordance with rule 5, and with the special object of giving an opportunity to all members to bring forward any proposals or suggestions that may have occurred to them and are in the interest of the Society. All new members elected at this meeting will receive a pass for the November Fête and other Shows and meetings.

The grand provincial Show, 1888, will be held in the Corn Exchange, Sheffield, on Friday and Saturday, November 16th and 17th. Schedules for this Exhibition have been forwarded to all members. Any further particulars may be had on application to either of the Hon. Secretaries, Mr. W. K. Woodcock, Hon. Sec., Sheffield Chrysanthemum Society, The Gardens, Oakbrook, Sheffield; or Mr. William Holmes, Hon. Sec. National Chrysanthemum Society, Frampton Park Nurseries, Hackney. A Chrysanthemum Conference will probably be held on the evening of the first day, further particulars of which will be duly announced. Visitors to Sheffield will be admitted after three on Friday at half-price on presentation of the return half of the railway ticket. The Midland Railway Company will convey exhibits at owner's risk at single rate for

the double journey provided they remain the property of the exhibitor. A number of cheap excursion trains will be run into Sheffield on Saturday, November 17th.

A meeting of the Floral Committee of the National Chrysanthemum Society was held at Westminster on Wednesday last, October 10th, but the exhibits were not numerous. Present: E. Sanderson, Esq., in the chair, and Messrs. H. Ballantine, W. Holmes, H. Cannell, C. Gibson, Lewis Castle, G. Gordon, R. Dean, G. Stevens, Kendall, R. Owen, and G. S. Addison.

Two blooms of the Japanese variety Edwin Molyneux were shown by Mr. Molyneux from Swanmore Park Gardens, the certificate awarded last year being confirmed. The blooms were very large, deep, the florets broad, intense crimson, with a gold reverse. Mr. R. Owen of Maidenhead sent a stand of new Japanese varieties, comprising Anna Roudière, exhibited last year; M. Levêque (Délaux), described as a sport from James Salter, with straight spreading florets of rather deeper colour (commended); Sam Henshaw, with incurving broad florets of a silvery pink tint; Mr. W. Holmes, very bright and fresh; Rose Beauty, with narrow fluted twisted rose florets (vote of thanks).

Messrs. H. Cannell & Sons, Swanley, exhibited specimens of select ornamental Beet leaves, and very fine double Tuberos Begonias of varied colours (vote of thanks). A certificate was awarded for the following:—

Chrysanthemum Dorée (W. & G. Drover).—A charming Japanese variety in the way of Mr. Garnar, with fluted, recurving, and slightly drooping florets, of a bright clear pale yellow tint.

CHRYSANTHEMUM TUBE FIXERS.

PER parcel post I take the liberty of sending you one of my Chrysanthemum tube fixers, and also an electro block showing the contrivance, suitable for printing, along with a description of it. As you will notice

FIG. 37.—TUBE FIXER. A. socket, B. ring.

(fig. 37) it consists of a tinned cast iron socket (A) containing an india-rubber ring (B) and is fastened to the top of the exhibition board over the hole, or it may be fastened to the under side of the board. By tightening or slackening the screws it will fit any size tube within certain limits, or the tubes may be made perfectly secure at any desired height for travelling. This contrivance gets over the defect of existing appliances, which raise the cup out of the tube, and at the same time raise the flower out of the water. I hope it will be taken up by some of the leading florists and sold at a cheap rate. I send you one fixed, and one not fixed, on board.—EDW. HARLAND, Hull and East Riding Chrysanthemum Society.

[The appliance sent is perfectly effective in its working, the tube being easily moved, and remains firm in any desired position.]

GRAPES SCALDING.

I NOW see that Mr. Bardney's article, page 162, was only intended for the very young and inexperienced, but I fear there are many experienced gardeners that differ on this subject from your correspondent. But I feel honoured by being numbered amongst this class. So this must be my excuse for daring to question some of his statements. There is much in Mr. Bardney's first article that I heartily endorse, but I still take exception to the point at issue. "It is no more difficult to scald Black Hamburgh and Madresfield Court than Lady Downe's." In spite of elaborate argument, Mr. Bardney has not come forward with

anything substantial to prove this statement. It is pure theory. He admits that it would be gross carelessness for a professional gardener to scald Black Hamburg, but he does not add that it would be the same thing to scald Lady Downe's. Every practical gardener knows that with the utmost care this Grape will scald more or less in the majority of cases in spite of every means of ventilation or care.

Mr. Bardney will admit that scalding Black Hamburg as badly as Lady Downe's would be gross carelessness. Conditionally it is admitted both are produced by the same cause. Possibly they are, but it would require an extra amount of the "same cause" to scald the former as badly as the latter. This is the chief difference between your correspondent and myself. So we are nearly agreed, for I have not brought forward any theory as to the reason of scalding, but wished to show they could not be compared as equals in the evil. Attention is drawn to the unseemly mixture of Lady Downe's in an early Hamburg house. Hardly anyone can be more sensible of this fact than myself, but it is only one case of many that could be cited on this point. But under the treatment given there is no excuse for the one variety scalding more than the other if they are both as susceptible to the evil. Overforcing is, no doubt, the cause of many ills that affect our Grapes. But I fail to see that Lady Downe's, grown as naturally as possible, can be overforced systematically. If so, it takes very little forcing to injure them. I have seen Black Hamburg forced very hard, but never remember seeing them scald.

That Lady Downe's will scald without the sun's direct action I think all will acknowledge, for houses that are shaded will sometimes scald as badly as those that are not shaded, except by foliage. There is something different about this Grape; it is either weak constitutionally, or it differs structurally, for the berries do not stand the same amount of treatment as the majority of other Grapes. When we get at the real cause of the scalding, then I think we shall find an infallible remedy, but at present, what appears adequate to prevent the evil in some places is totally inadequate in others. — JAMES B. RIDING.

THAT this annoying phenomenon is more generally prevalent than the knowledge necessary to avert its disastrous effects the various opinions of numerous correspondents fully testify. Having had some experience in dealing with some rather persistent attacks I venture to submit the ideas I have formed as to its cause and prevention.

Regarding the cause, I think we are all agreed that the wrong disposition of heat and moisture are the predominant forces which produce the effect; but in reference to the action of these agents there is, I perceive, much divergency of opinion. In the correct elucidation of Mr. Young's proposition, "What, then, is the cause of moisture being condensed on the berries?" will I venture to say be found the lever that will give the uninitiated power to cope with the difficulty. This correspondent's theory "That an overheated atmosphere caused by the sun shining suddenly on the house without sufficient ventilation, as well as insufficient heat in the pipes to prevent the berries becoming cold," may, to Mr. Bardney's mind, appear somewhat vague, and possibly heterodox if he is a firm believer in "somebody's" theory on the "liquefaction of vapour." That the writer of that useful pamphlet may be well versed in reference to the formation of dew on the open ground, and in that direction his theories may be infallible; but when it comes to the natural action of air, heat, and moisture in an artificial structure like a glass house they may in many instances be at a discount. "Condensed moisture on the berries of Grapes is due to a low temperature," says Mr. Bardney, "and the berries being naturally colder than the atmosphere they cool the air in contact with them, and the consequence is that some of the vapour it contains is quickly deposited. As the temperature rises the air takes up the moisture which it had previously deposited, and the result is evaporation. Instead of condensation taking place when the temperature rises evaporation takes place, and the air is charged with heated vapour that practically 'stews' the berries unless means of escape for it have been provided." This I take to be the gist of Mr. Bardney's arguments, and in it I think we can trace a desire to prove the case by analogy with the generally accepted theory of the deposition of dew—viz., the cooling of an atmosphere laden with moisture, and consequently its inability to retain it suspended in an invisible form, hence it deposits in the form of tiny globules of water on points of leaves, grass, &c. This form of condensed moisture occurring in vineries and plant houses nearly every cultivator is familiar with, caused undoubtedly by early closing with sun heat and plenty of moisture being distributed, consequently a high humid atmosphere followed by a rapid fall and deposit of dew if there is insufficient heat in the pipes to maintain the temperature above dew point. But in all well-regulated vineries this shutting up with a strong sun heat should only be practised during the early part of the growing season, and then the advice to allow a low night temperature is open to grave question if this course is followed. The first part of Mr. Bardney's quotation will be correct enough, "Condensed moisture on the berries of Grapes is due to a low temperature," but the second part, alluding to berries being naturally colder than the atmosphere and thereby favouring a deposit of dew, is altogether contrary to the present phase of "liquefaction of vapours," as I cannot but think that if Mr. Bardney will recollect in cases where moisture has been condensed owing to a low temperature he must have observed the partiality the liquefied vapour has for points of leaves, tendrils, and other sharp protuberances. But it is not in this fact that injury is caused, he argues, but when the temperature rises, and this moisture is again absorbed or evaporated from the berries and the leaves, this vapour-charged and highly heated atmosphere "practically stews the

berries." No mention is made as to how the leaves and tender shoots fare under this ordeal. Possibly Mr. Bardney's theory on leaf-scorching is correct, which is, I believe, that such an occurrence cannot take place if means are taken to insure the preservation of a moisture-laden atmosphere. We never hear of Cucumbers being injured by "stewing," though they are compared to Grapes subjected by some successful cultivator to abnormally high temperatures.

Again, why does scalding generally occur on the shady side and in the centre of the bunch? If Mr. Bardney's theory is correct all and every berry should fare alike; also for a full and complete remedy a ready means of escape for the moisture evaporated by the sun raising the temperature is recommended, though some correspondents affirm that free ventilation was only partial in staying the mischief. To that I think we must look in another direction for the solution of the enigma. Mr. Young's theory, as given at the commencement, though perhaps a trifle too concise, is, I am inclined to think, the correct one. The generally accepted law of condensation may be right enough and work on exactly the same principle in the open as in a glass structure, but when we come to evaporation the artificial restrictions materially affect its working. Under natural conditions scalding of fruits or scorching of foliage seldom or ever occurs owing to the freedom of evaporation of moisture deposited on vegetation. But under artificial treatment the case is different. The sun shining on the house raises the temperature, and evaporation takes place—that is, the heated air by chemical affinity absorbs moisture from surrounding substances up to this point. I agree with Mr. Bardney and somebody's theory on the "liquefaction of vapours," but here I depart, owing to artificial means setting aside the common rule of Nature. The sudden rise and compression in the temperature of a glass structure when closed, and sometimes even when ventilated, is very rare in Nature, therefore we may expect to find results the causes of which are apparently obscure though natural enough when understood. This, then, is my theory, that a rapid rise of the temperature, owing to the sun shining suddenly on the house, enables the atmosphere to absorb moisture; the berries which have arrived at a period of density of tissue are unable to heat so quickly, consequently by a law of Nature any object of a less temperature than the air it is surrounded by cools the air about it, so that if the air is charged with moisture the influence of the cold body renders it incapable of carrying it, consequently it is thrown down or condensed on that body, as illustrated by the objectionable state of affairs known amongst Grape growers as "sweating." This moisture not being evaporated quickly becomes heated, consequently the scalding of the skin of the berry takes place. Why the berries are generally most damaged on the side opposite to that nearest the sun is a circumstance that is explained by the more rapid warming of their substance and their non-liability to act as refrigerators.

This, then, I think is the solution which was shadowed by Mr. Young, and the main difference between Mr. Bardney and the foregoing is in the way the moisture is condensed on the berries, but it is in the proper elucidation of this circumstance that enables us to propound a remedy, or, better still, a preventive. With Mr. Young I favour sufficient heat in the pipes to prevent the berries getting cold, and also to obviate a too humid atmosphere, and coupled with intelligent ventilation, Lady Downe's or any other variety of Grape may be grown without any scalding taking place.

As to some varieties of Grapes being more susceptible to this form of injury than others, I venture my humble opinion that all Grapes are liable to scald if proper precautions are not taken to prevent it, though some varieties more than others, owing to the physical structure of their berries, Lady Downe's especially so, the large solid formation of its seeds, and general dense construction, renders it unfit to withstand rapid changes of temperature. This is, I think, proved by the injury taking place during the stoning period, when the solidity of the berry is increasing, while at the same time the skin is in as tender a condition as previous to attaining this stage, and in many cases the treatment they receive in respect to damping down and closing being continued the same as earlier in the season, consequently aggravating the evil. I am of opinion that if the treatment that is generally given when colouring commences—viz., more air and drier, but not necessarily a lower temperature, was put in force during stoning, scalding would soon be unknown.—M. COMBE.

MR. BARDNEY does not strengthen his case in the least on the main question at issue by his remark that his article was intended for the young gardener and amateur. Mr. Bardney now says that he never suggested that these two varieties grown together in the same house would both scald, but he did say that it was just as easy to scald the Black Hamburg as Lady Downe's. I conclude by the above statement that he has had disagreeable experience in the scalding of the Black Hamburg; if such is the case I would advise him to alter his practice. The "main points" which he thinks I, in common with your other correspondents, have overlooked, have not the least bearing on the portion of his article which I disputed. If he thinks he will succeed in convincing the readers of the Journal, he has a hard task before him. Surely he cannot be in earnest concerning the part of his article which I did not comment on, and which he says tells against me. As a matter of fact he has already had his answer when I stated that it "required gross carelessness to scald the Black Hamburg." Can Mr. Bardney prove that the Black Hamburg will scald under the slight conditions which will scald Lady Downe's? Your correspondent also professes to be amused at my allusion to the cost of Grapes, it being foreign to Grapes

scalding, though it has as much practical bearing on the subject as his own remark at page 260—viz., "Such action may be tolerated when the cost of production and the value of the crops are not placed side by side. It is the reverse of economy to leave the house open and maintain the desired temperature by the aid of fire heat. Expenses of this nature are not warranted at the present price of Grapes." I can quite understand his making such statements. Fire heat is used very judiciously by me. In the same article, a little further on, we read on syringing Vines: "I do not believe in such a practice, because it is liable to injure the bloom." If these Grapes were so good (and I do not dispute the fact) through this heavy syringing night and morning, why should Mr. Bardney qualify his statement in such a manner? If these Vines are really syringed in the manner as stated, what of the bloom? The condensation as referred to by me is very different to that which is deposited by Nature in the open air. If Mr. Bardney has a house of black Grapes, let him keep the ventilators closed until the sun has shone a short time on the house, and he will soon notice a mist on the Grapes. The above is practically what happens to Grapes when they scald, through the house being too close and cold, or even if shut up too early. —A. YOUNG.

I AM very pleased to read the interesting communications which appeared in your last issue. According to Mr. Bardney's communication on page 319, he is of opinion that I think the scalding of Lady Downe's Grape constitutional. I fail to conceive where he could draw such conclusions. What I said was this—that Lady Downe's would scald sometimes under the best of management, and I contend that it will, and especially in dull wet seasons. Nevertheless, I do not say that it cannot be grown without scalding, and if Mr. Bardney has grown it without being so affected, or any other correspondent, I should be pleased to read the cultural instructions. I wish to draw attention to a house of Grapes that was under my management some time ago. The house in question was a late one, and a lean-to due south, with the necessary appliances with respect to artificial heat, but nevertheless we did not think it necessary to use it to encourage the commencement of growth, but, on the other hand, allowed the Vines to start naturally. The varieties consisted of Black Hamburgh, Black Alicante, Lady Downe's, and Mrs. Pinee. Growth commenced in March, the first named taking the lead by about ten days or so. When they had all broken well into growth we thought it necessary to turn a little fire heat on, and gradually increasing it as growth advanced. Let it be understood that the object of these remarks is to draw particular attention to the stoning period. Black Hamburgh led the way, and the others followed in the order they are given, and, notwithstanding the attention they received with respect to air-giving and an increased artificial temperature, together with a dry atmosphere, Lady Downe's was the only one affected, and to quote the words Mr. Bardney uses, scald into "bits of bunches." This seems a singular thing to me. Was this "fancy" or gross carelessness? It cannot be attributed to over-forcing, as I have shown, so perhaps some of your correspondents will take the matter up and give their opinion. I leave the question open as to whether the scalding of Lady Downe's is constitutional or not. —R. KIRBY.

PLANTING FLOWER BEDS FOR SPRING.

FLOWER beds when cleared of their summer occupants may be levelled with the rake, and again be filled with such spring-flowering plants as Golden Gem Viola, Daffodils, the common Primrose, and Alyssum saxatile compactum, four distinct shades of yellow. Myosotis dissitiflora, Imperial Blue Viola, Nemophila insignis, and Aubrietia deltoidea afford a like number of shades of colour, ranging from light blue to purplish lilac. In white, Daisies, Arabis alba, and Dean's Viola White Bedder will be found three white free-flowering plants; and in red Daisies, Blood Red Wall-flower, and Silene pendula ruberrima we have materials for supplying masses of red and pink. In addition to Snowdrops, Crocuses, Hyacinths, Tulips, and other bulbous plants, there are many hardy perennials besides those enumerated above which are suitable for embellishing the spring garden; but those already mentioned, if the colours are judiciously arranged in masses, will be found sufficiently floriferous, effective, and varied in colour to render the garden in spring as charmingly beautiful as it can be made in summer.

The beds in which it is intended to plant the double Daisies may have a sprinkling of fresh soot mixed with the surface soil as a preventive of the attacks of the grubs of the daddy-longlegs, which are frequently very destructive to these old-fashioned spring-flowering plants. In every case take up the plants with soil attached to the roots, and plant the same depth in the ground as they were before, making the soil moderately firm about the roots. —H. W. WARD.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 9TH.

A SMALL gathering of exhibits greeted the members of the Committee and the few visitors who assembled in the Drill Hall, James Street, Westminster, on Tuesday last, but the group of Ferns from Tottenham was one of exceptional merit.

FRUIT COMMITTEE.—Present—Dr. Robert Hogg (in the chair), and Messrs. H. J. Veitch, J. Lee, S. Ford, A. H. Pearson, J. Burnett, R. D. Blackmore, W. Warren, J. Cheal, G. T. Miles.

W. Roupell, Esq., Roupell Park, was awarded a cultural commendation for excellent samples of Canon Hall Muscat Grape, grown in an

11-inch pot; also Gros Colman and Black Hamburgh grown in an unheated house for over fifty years. Mr. C. Ross, Welford Park Gardens, Newbury, sent specimen of a seedling white Grape; and Mr. J. Bradshaw, Downshire Gardens, Hillsborough Castle, Co. Down, sent a specimen of a seedling white Grape named Lady Downshire, but no award was made for either. Mr. G. Bolas, Hopton Hall Gardens, Wirksworth, showed specimens of Cherry Late Duke (vote of thanks). Messrs. Veitch & Sons, Chelsea, exhibited twenty-seven dishes of Plums, representing that number of distinct varieties (silver medal). From the Society's garden, Chiswick, was also sent a collection of seventeen dishes of Plums. Messrs. Carter & Co., 237, High Holborn, sent neat even specimens of their New Model Onion, described as a cross between Rousham Park Hero and Magnum Bonum. Mr. R. Dean, Bedford, sent two plants of Laxton's outdoor Tomatoes. From the Society's gardens came samples of the Dracena-leaved Beet (Veitch), and Endive Queen of the Winter. Messrs. Lloyd, Lawrence & Co., 21, Worship Street, London, E.C., sent several samples of farm and garden tools, comprising seed drills and double wheel hoes.

FLORAL COMMITTEE.—Present—G. F. Wilson, Esq., in the chair, and Messrs. W. Wilks, J. Laing, H. Herbst, W. Goldring, J. Walker, B. Wynne, W. Wildsmith, W. Holmes, R. Dean, C. Noble, C. Pilcher, J. Durney, H. Ballantine, H. M. Pollett, J. O'Brien, E. Hill, Shirley Hibberd, G. Duffield, and T. Baines.

Mr. Walton, Burnley, exhibited a collection of Ferns, amongst them being eight plants of Adiantum farleyense, which were said to have been raised from spores sown on February 23rd, 1887. They were taken from a large plant in the possession of E. Ecroyd, Esq., Edgond House, Burnley, Lancashire. In a note accompanying the plants it was stated that "the spores were only found after much searching, being in the overlapping pinnules of the frond. The first frond from the prothallus appeared some six months after sowing, the whole of the plants germinating being reared. The batch of plants should prove conclusively that Adiantum farleyense may be raised true from spores, when the spores can be obtained true from extra strong plants that have been isolated from any other Adiantum having any affinity to it." A vote of thanks was accorded for the plants, which were evidently the true A. farleyense, but the Committee expressed no opinion on the point to which attention was specially called in the letter. It has been claimed before that this Fern has been raised from spores, and the accuracy has been as frequently questioned by other Fern growers.

Mr. S. Ford, Leonardslee Gardens, Horsham, sent flower trusses of Nerine coruscans highly coloured. Messrs. Wm. Paul & Son, Waltham Cross, showed flowers of an H.P. Rose named Denmark, in the way of La France, of similar colour and fragrance; to be seen again.

Messrs. J. Veitch & Sons, Chelsea, exhibited plants of Amasonia calycina, Bouvardia President Cleveland, Amaryllis Autumn Beauty, Canna Ulrich Brunner, and Begonia John Heal (vote of thanks). All these are well proved plants of great merit, and they have been several times noted. Messrs. H. Cannell & Sons, Swanley, exhibited a collection of handsome single and double Tuberous Begonias, two of the latter being certificated, and votes of thanks were also awarded.

Mr. H. B. May, Upper Edmonton, contributed an extensive and handsome group of Ferns, representing about 200 species and varieties. All the plants were in excellent health (silver-gilt Banksian medal).

CERTIFICATED PLANTS.

Laelia porphyrites (Baron Schröder).—A supposed natural hybrid, a dwarf neat Orchid with medium size flowers, the sepals and petals tinged purple, the lip of an intensely rich crimson, and light in the throat.

Nepenthes Ficksoniana (J. Veitch & Sons).—A hybrid between N. Veitchi and N. Rafflesiana, named after the late Professor Dickson of Edinburgh. Pitchers large, long, green, beautifully mottled with crimson. A very handsome free variety.

Tuberous Begonia General Chichester (H. Cannell & Sons).—A double variety with large full deep rose coloured flowers of good shape.

Tuberous Begonia Mrs. Stark (H. Cannell & Sons).—A fine double yellow variety, blooms full and handsome.

Chrysanthemum Elsie (G. Stevens).—A beautiful creamy yellow variety, Japanese reflexed type, florets fluted and recurving.

Adiantum Waltoni diffusum (H. Walton, Brierfield, near Burnley).—A freely growing diffuse but graceful variety; a seedling from A. Waltoni, a so-called hybrid sent out in June, 1888.

Canna Ulrich Brunner (J. Veitch & Sons).—A very large flowered variety, deep rich scarlet, particularly showy and handsome.

NATIONAL APPLE AND PEAR CONFERENCE.

THIS Conference, which opens next week in the Royal Horticultural Society's Gardens at Chiswick, promises to be of great interest to fruit growers and of wide general importance. At a meeting of the Executive Committee held on Tuesday last, present: Dr. R. Hogg in the chair, and Messrs. A. H. Pearson, J. Walker, W. Wilks, H. J. Veitch, Wm. Paul, Shirley Hibberd, J. Douglas, W. Warren, J. Cheal, F. J. Lane, A. Dean, W. Wildsmith, J. Hudson, A. Turner, and J. Wright, the following arrangements were made:—The fruit, which will comprise selections from various districts, is to be staged early on Tuesday next, and the Conference will be opened by the Council of the Society at 3 p.m. On Wednesday papers will be read by Mr. G. Bunyard on the "Growth of Apples for Profit;" by Mr. William Paul on the "Growth of Pears for Profit;" by Mr. T. Francis Rivers on "Stocks for Apples and

Pears:" by Mr. W. Wildsmith on the "Fewest Varieties of Apples and Pears necessary to insure supplies of ripe fruit from August to March;" "Pruning Apple and Pear Trees," by Mr. Shirley Hibberd, Dr. Hogg being nominated to preside at the meeting. On Thursday the subjects are "Canker in Fruit Trees," by Mr. J. Douglas and Mr. E. Tonks; the "Enemies of the Apple and Pear," by Mr. J. Fraser; "Varieties of Apples for Sussex and their Culture in Heavy Clay Soils," by Mr. J. Cheal; "Renovation of Old and Formation of New Orchards in the Midlands," by Mr. W. Coleman; "Apples and Pears Suitable for Cultivation in Scotland," by Mr. M. Dunn, Mr. Shirley Hibberd presiding. On Friday the papers to be read are on "Compensation for Orchard Planting," by Mr. W. E. Bear; "Fruit Production and Distribution," by Mr. E. J. Baillie; "Railway Charges for Carriage," by Mr. D. Tallerman, Mr. T. B. Haywood being nominated to preside on the occasion. The meetings are to commence at 1.30 on each day, and discussions are expected to follow the reading of each paper. Visitors from the country who propose attending the meetings may be reminded that the Gardens are within five minutes' walk of the Acton Green station on the Metropolitan District Railway, and trains run in half an hour from the City stations every twenty minutes. Visitors from the south will find trains from Clapham Junction to Chiswick station, which is within a mile of the Gardens.

EVENTS OF THE WEEK.—To-day (Thursday) the Crystal Palace Hardy Fruit Show opens, and at 2 P.M. a Conference of Fruit Growers and a meeting of the British Fruit Growers' Association will be held. At 5.30 P.M. the Annual Dinner of the United Horticultural Benefit and Provident Society will be held in Cannon Street Hotel, Dr. R. Hogg presiding, and H. J. Veitch, Esq., in the vice-chair. The Crystal Palace Fruit Show will be continued on Friday and Saturday. A General Meeting of the National Chrysanthemum Society will be held at 7 P.M. on Monday, October 15th, in Anderton's Hotel, Fleet Street; E. Sanderson, Esq., in the chair. The National Apple and Pear Conference in the Royal Horticultural Society's Gardens, Chiswick, will be opened on Tuesday and continued until Friday, particulars of the programme being published on another page.

— **ROYAL HORTICULTURAL SOCIETY.**—It has been decided to hold a Grand Horticultural Exhibition in the Temple Gardens on the Thames Embankment on or about the last week in May, 1889, the Benchers of the Temple having liberally given their consent for the Society to occupy the Gardens during two days for that purpose.

— A PROSPECTUS before us shows that the business of MR. SAM DEARDS is being converted into a limited liability company, to be worked with a capital of £25,000 in shares of £1 each. The prospectus shows the various medals that have been awarded to the Victoria dry glazing and other of Mr. Deard's specialties, most or all of which have been from time to time described and illustrated in this Journal. Mr. Deards accepts the position of manager to the company on terms stated in the prospectus.

— THE death of MR. DAVID WOOSTER at the age of sixty-four was recently announced as having taken place at Bayswater after an illness of over three years. Mr. Wooster was formerly associated with Loudon, whom he assisted in the compilation of several important works. A work on Alpine plants was also published by him, and for some years he was also associated with Sir Walter Trevelyan at Wallington.

— SOME inquiries have reached us in respect to a HORTICULTURAL AND TECHNICAL COLLEGE for students in Kent. We are not in a position to give advice on this matter, as information essential for this purpose is not given in any prospectus we have seen. In a copy before us we find a tempting curriculum displayed, but we look in vain for names of proprietors, teachers, officers, or manager. Obviously on the character and ability of these, and the means at disposal, depend the stability and usefulness of a scholastic or collegiate institution, and until full particulars are furnished on these matters we are justified in regarding the scheme as speculative. At the same time we are convinced that knowledge cannot be bought at any college with which we are acquainted that will enable "students" to compete successfully with the leading gardeners, private or commercial, trained in establishments where actual work is conducted to a satisfactory issue.

— **EXTRAORDINARY ONIONS.**—A correspondent sends the following note:—"At Mr. Deverill's Royal Seed Stores, Corn Hill, may now be seen two dozen of his new Onion, Ailsa Craig, probably the largest bulbs ever placed on an exhibition table, the largest of which girths 18 inches in circumference and weighs 2½ lbs., less 1 ounce, the total weight of the twenty-four Onions being very nearly 47 lbs. Mr. Murray, the head gardener to the Marquis of Ailsa, Culzean Castle, is the grower, and after such a magnificent display we are sure the Oxfordshire growers of Onions will acknowledge that they do not stand alone in the production of fine Onions. We are assured that not for the last twenty-nine years has the like been seen in Banbury, and for the present Ayrshire is the premier county for Onions."

— **GARDENING APPOINTMENT.**—Mr. William Maybury, late head gardener at The Rookery, Dorking, has been appointed head gardener to J. Godfrey, Esq., Brooke House, Sandwich, Kent.

— AT the present time *HELIANTHUS MULTIFLORUS RIGIDUS* is one of the most showy plants in the borders. It has run up to a height of 7 feet, and its bright yellow flower heads are much prized for the decoration of tall vases when in a cut state.

— SMALL plants of *FUCHSIA PROCUMBENS* covered with its crimson berries are very attractive and useful for draping the edges of the greenhouse or conservatory stages. It is a plant not often seen, but generally admired when well cultivated.

— *CUPHEA PLATYCENTRA* is useful when planted in a mass in the flower garden. It is not often used now for embellishing beds and borders, but where it succeeds it is certain to meet with many admirers. Cuttings strike readily in the spring and rapidly grow into neat little bushes.

— **PRESENTATION TO MR. A. J. BROWN.**—On Thursday last a public meeting was held in Lindfield, the object being to present Mr. A. J. Brown, who is retiring from the charge of the Finches Gardens, with a purse containing £8, as a mark of appreciation for the service he has rendered to the village during the nine years he has had charge of the gardens named. Mr. Brown is also local Secretary for the Gardeners' Orphan Fund.

— A VERY fine example of *TROPEOLUM SPECIOSUM* is growing at the base of a north wall of the Dairy, Highfield, Heckfield. The shoots of this season's growth measure 12 feet long. At the present time there are many fine blooms upon it. The effect it produced some time since when covered with flowers can easily be imagined. Where this plant flourishes it is splendid, but how seldom do we see it in thoroughly good condition?—M.

— **LILIUM AURATUM AND ROSES.**—Anyone wishing to improve the appearance of their Rose beds during September and early October, when there is a scarcity of blooms upon Hybrid Perpetual Roses, could not do better than plant bulbs of this Lily. Good bulbs are capable of producing stems carrying as many as ten and twelve large blooms the first year upon each. This form of after-decoration of the Rose beds does not in any way interfere with the welfare of the Roses.—E.

— **THE WEATHER IN LIMERICK.**—An event without a parallel in the memory of anyone occurred on the morning of the 2nd, when I awoke to find 8° of frost. Dahlias, Heliotrope, Paris Daisies, Calceolarias, annuals in variety, French and Runner Beans, &c., were cut down to the ground. Geraniums were not much hurt, yellow Daisies not at all injured. The days since have been cold, rain falling frequently. Each night we have had from 2° to 6° of frost. Everything is cut down fully a month earlier this year. The swallows are still as plentiful as they were in the summer.—R. WELLER.

— **MESSRS. CASSELL & COMPANY** send us a specimen with plate of a new serial publication they are issuing entitled "THE WORLD OF ADVENTURE," and ask our opinion thereon. The work, which is to be published monthly, is mainly intended for young people, and is to be "attractive in text and illustrations, and at the same time of an elevating character." The specimen copy, which consists of sixty-four pages of matter and illustrations, well fulfils these conditions, and the work will be interesting to, and no doubt read by, old as well as young. We commend this new serial to the attention of our readers.

— **TOM THUMB AGERATUM.**—This is the best Ageratum that I know. The plants from which I have propagated my stock the last twelve or fourteen years were selected from seedlings raised from a packet of seed had under the above name, and during that period I have supplied friends with cuttings and plants of it. It is the admiration of

all who see it, and this is not to be wondered at, seeing that it is of dwarf and constant habit, a good grower and free flowerer, and the masses of colour, a beautiful grey, are very distinct and effective when contrasted with the surrounding masses of scarlet, yellow, pink, white, and blue. A few plants of this *Ageratum* should be potted at once.—H. W.

— **HELIOTROPES MISS NIGHTINGALE AND WHITE LADY.**—Anyone in want of a good *Heliotrope* for bedding could not do better than procure the first named variety. It is of medium compact habit, the foliage and flowers being dark. For covering the back wall of a greenhouse to which is admitted a fair amount of light no better plant could be used than *White Lady*. Its growth is not too robust, while it flowers abundantly and the fragrance is especially pleasing. It is well to closely prune in the shoots to one or two eyes in the early spring of each year, or the branches are liable to become straggling and bare. Annual pruning of the shoots renders the succeeding growth free and neater in appearance.

— **HALE'S EARLY PEACH.**—If anyone wants a good early companion for *Bellegarde* it will be found in *Hale's Early*. If the true form is obtained this will be found of fairly strong growth, and provided the district favours outdoor culture of Peaches, a sure bearer. It colours beautifully, usually ripens about the middle of August, and may be said to be of fairly good quality. This and other early varieties, notably *Waterloo* and *Rivers' Early York* ought to be most extensively grown in gardens where the late Peaches generally fail to ripen. Our collection of varieties on the open walls is somewhat limited, and I, and doubtless many others, would be glad to hear what has succeeded well in other gardens this season.—W. IGGULDEN.

— **BELLEGARDE PEACH.**—If limited to the cultivation of one variety of Peach, whether under glass or in the open, *Bellegarde* would be my choice. It possesses a good constitution without being too robust, sets well whether forced or otherwise; the fruit are of good size, colours grandly if given fair play, while the quality is first class. It succeeds admirably on the open walls here, and even in such a season as we have nearly passed through all have ripened capitally. The fruits were certainly smaller than usual, but the colour was as good as ever, and good judges of fruit expressed the opinion that the quality surpassed anything tasted previously this season. In other words, *Bellegarde* ripened in the open was more pleasing to the palate than fruit ripened under glass with all its supposed advantages.

— **GHENT AZALEAS.**—These as well as the old *Azalea pontica* are lovely twice in the year—that is, when they are in flower and in autumn. Their bright crimson foliage is now most beautiful. The ordinary smoke of large towns does them no harm whatever. They are not really effective when planted on the dotting system with *Rhododendrons* and other evergreens, though they look well during the time they are in flower. When destitute of their foliage they have, from a distance, the objectionable appearance of looking like so many dead plants. This objection is overcome by planting them in masses instead of, say, alternately with evergreens, and with a good background of the latter they are shown to great advantage. They will grow well in any good loam where *Rhododendrons* thrive, but make more rapid growth if plenty of leaf soil is mixed with the loam.—W. D.

— **MR. J. MALLENDER** sends his usual SUMMARY OF METEOROLOGICAL OBSERVATIONS AT HODSOCK PRIORY, WORKSOP, NOTTS, for September 1888. Mean temperature of month, 53.1°. Maximum on the 2nd, 69.1°; minimum on the 27th, 32.9°. Maximum in sun on the 14th, 126.4°; minimum on the grass on the 26th, 28.2°. Mean temperature of the air at 9 A.M., 54.1°. Mean temperature of the soil 1 foot deep, 55.4°. Temperature fell below 32° on the grass on two nights. Total duration of sunshine in month, 101 hours, or 27 per cent. of possible duration. The brightest day was the 13th. We had two sunless days. Total rainfall, 0.91 inch. Rain fell fourteen days. Average velocity of wind, 6.1 miles per hour. Velocity did not exceed 400 miles on any day, and fell short of 100 miles on twelve days. Approximate averages for September—mean temperature, 55.8°; sunshine, 108 hours; rainfall, 2.51 inches. Cold, dry, fine, and very calm weather, and a good deal of haze and fog. The mean temperature of the past quarter is lower than any of the last thirteen years, and probably for a much longer period.

— **A COLD WEEK.**—A daily paper says:—"The past week has been unusually cold in all districts, and in London the temperature of the six days, Monday to Saturday, was in every respect lower than that registered during any similar period in the past sixteen years. The

highest temperature of the week was only 51°, or 4° lower than the lowest previous maximum, and at least 10° lower than the maximum recorded in ten out of the sixteen years. In October, 1886, an unusually warm month, the thermometer on the 4th rose to 80°, or 26° higher than last week's maximum. As regards the night temperatures it appears that the actual minimum for the six days was also 4° lower than the lowest previously recorded, and strangely enough it was also at least 10° lower than in ten of the years in question. Although ground frost is not very unusual at this time of year, there is no previous instance of the thermometer in the screen falling as low as 32°. Last week, however, it did so on three occasions, and the mean of all the night readings was only 32.5, or about 2° lower than the average minimum for December and January."

— **THE WEATHER IN THE NORTH.**—A fortnight ago, after the cold sunless season through which we have passed, there really did seem a promise of a few weeks bright and somewhat settled weather; but alas! our hopes were raised only to be disappointed, rain and fog soon followed, and on the night of the 1st October we were visited with 10° of frost. Of course, everything out of doors is now done for the season. *Chrysanthemums*, where not well protected, are cut down as badly as last year, when we were visited with 8° on September 28th, late varieties now, as then, suffering most. The difference in the hardiness of varieties is very marked, *Peter the Great*, *Fair Maid of Guernsey*, *Boule de Neige* I notice are particularly tender, while many others, particularly where the buds have been "taken" and the foliage become matured, have stood it much better. We have usually felt pretty secure here until about the second week in the present month, but our season of safety is apparently becoming shorter. We have gathered one small dish of *Scarlet Runners* only. *Dwarf Beans* have not even flowered, and *Vegetable Marrows* never grew larger than a very small pod of peas. Surely this is gardening under difficulties.—WM. JENKINS, *Durham*.

— **THE WEATHER AND THE CROPS.**—Mr. G. R. Allis writes from Old Warden, Biggleswade—"The sudden change in the weather on the 2nd inst. came as a surprise. The day throughout was heavily overcast, cold rain and sleet falling, with a very low temperature, the mercury of the thermometer only rising 5.42°, or 10° above freezing point. The mercury went down during the night to 24°, or 8° of frost. This was unusually severe for so early in the month, making sad havoc with vegetables—*Kidney Beans*, *Peas*, *Marrows*, *Endive*, outdoor *Cucumbers*, also *Cauliflowers*. *Dahlias*, *Heliotropes*, *Asters*, *Sweet Peas*, *Zinnias*, and a host of other things were completely spoiled. The same amount of frost occurred on the 13th October last year. The thermometer has registered frost on most nights since the 2nd from 5° to 7°, but the crowning frost of the season occurred on the morning of the 8th, the mercury falling to 22°, or 10° of frost. The market gardeners of the district have suffered in the loss of fine crops of *Vegetable Marrows*, *field Cucumbers*, and *Runner Beans*, and it is feared that a good breadth of *Onion* seed will have been spoiled that was late in coming to maturity; but it will be some consolation to those whose crops of *Potatoes* showed such early signs of disease in the haulm to find, on lifting, much better results than could have been expected some weeks ago. The crops on light sandy soils are yielding fairly well, with but few diseased tubers."

— **AN AMATEUR'S HOUSE.**—Mr. Edgar Newton has erected in his garden at Hitchin some houses with his "reform" system of glazing, which has been well described in the *Journal*. The first is span-roofed, about 30 feet long, with stages of corrugated iron on each side, and on these are shallow boxes 6 inches to 8 inches wide, containing plants of *Tomatoes*, which are grown on the single-stem plan to wires under the roof glass. They are heavily cropped with fine and richly coloured fruit. In another house a *Black Hamburgh Vine* is carrying a crop of *Grapes*, the bunches of good form, and the berries well finished in colour. He also grows *Ferns* and choice flowers for cutting and decoration. Trained to the back wall *Maréchal Niel Rose* and *Zonal Pelargoniums* are well grown, tall plants of the latter being always in flower. Shelves are provided near the glass for dwarf-growing and other plants, and the arrangement may be worth noting. A narrow strip of wood is placed edgewise the entire length on both sides, and the shelf has a gentle fall from the middle to the ends, where a hole is bored and a lead pipe fitted in to carry off the waste water. There is no drip on the plants beneath, and anyone can attend to the watering without getting at all wet.—T. G.

— **BIRMINGHAM GARDENERS' MUTUAL IMPROVEMENT ASSOCIATION.**—The first meeting of the autumn session was held at the Midland Institute on Tuesday evening, October 2nd. The President, Sir Thomas Martineau, occupied the chair, and more than 100 members

were present. The President warmly congratulated the members upon the great success of the Society and the excellence of the programme for the autumn session. He likewise drew their attention to the valuable horticultural education such societies and meetings must be giving to the younger members of the profession. He remembered with very great pleasure presiding at the first meeting which was held to inaugurate that Society, inasmuch as it was one of the most useful and one of the most successful societies that sprang into existence during the three years of his mayoralty. At the close of his remarks Mr. R. Parker, The Gardens, Impney Hall, Droitwich, gave a most practical, instructive, and interesting paper on "Essential Points in Connection with the Successful Cultivation of our Hardy Fruits." He dealt with his subject in an exhaustive manner, dwelling upon the importance of a wise selection of stocks; of the value of a high, dry, and sheltered position, and a limited selection of such varieties as are suitable for the district in which they are to be grown. A lengthy discussion followed, which brought out much useful information, and a suggestion from Mr. A. Outram that a record should be kept in the library for the use of the members of such varieties that are known to do well in the district. A unanimous vote of thanks was tendered to Mr. Parker for his valuable paper, a similar vote being most enthusiastically tendered to Sir Thomas Martineau for presiding. The meeting then adjourned till October 16th.—J. H.

— A FREE course of ten lectures on **ELEMENTARY BOTANY AND THE PRINCIPLES OF GARDENING** will be delivered in the Lecture Hall of the Mechanics' Institute, Woolton, Liverpool, on Thursday evenings, at 8 P.M., commencing on Thursday, October 11th, by R. J. Harvey Gibson, M.A., F.R.S.E.L., Lecturer on Botany in University College, Liverpool. The main object of the course will be to give an account of the structure and uses of the various parts of flowering plants, and the principles on which they are artificially cultivated. The origin of cultivated from wild plants, the diseases to which plants are liable, and the means adopted for the prevention and cure of such, will also be discussed. No scientific knowledge will be assumed, and the lecturer will aim at making the lectures as free from technicalities as is consistent with accuracy. A detailed syllabus will be distributed previous to each lecture, giving an abstract of the subjects considered therein. The lectures will be illustrated by magic lantern views, and, as far as possible, by actual specimens. The following is a detailed statement of the subjects of the individual lectures:—Lecture I. Animal and plant life, and the relation of plants to animals in nature. II. The general structure of the plant. The food of plants, and the method in which it is collected. III. The structure and uses of the various parts of the plants. IV. The structure and uses of the several parts of the flower, and the way in which they become altered to bring about cross-fertilisation. V. The origin and growth of the adult plant from the seed. VI. The means artificially adopted for improving and multiplying the plant. VII. The origin of cultivated from wild plants, illustrated by examples. VIII. Parasitic plants, how they live, and how they may be got rid of. IX. Carnivorous plants. X. The plants of the past, and their relation to the plants now existing on the earth.

SEASONABLE NOTES ON FLORISTS' FLOWERS.

AURICULAS.—Judging from what I have seen with others, and from my own small collection, this cold summer with its cloudy skies and low temperature has been favourable to the Auricula. The plants look sturdy, nor has there been so much autumn bloom as usual. There are some sorts which are more inclined to do this than others, but even with these I do not see so many autumn trusses. Where they do appear it is better at once to remove the pips if the stem has not risen much above the foliage, as there is less likelihood of the stem damping off and so, perhaps, injuring the plant; but if the stem has shot up to any height the top may be pinched off. All plants that have thrown these autumn flowers should be carefully watched, as the stem in decaying may injure the plant. For the same reason it will be necessary to remove all dead and decaying foliage from them, for there is nothing which is so injurious to the well-being of the Auricula as damp. The frames should be carefully gone over, and if there is any sign of green fly it should be at once got rid of. If not very numerous the application of a brush may be sufficient, only care should be taken to brush the under side of the leaves, and in so doing to hold the pot on one side so as not to allow the aphids to fall on the surface of the soil, for if they do they will inevitably soon crawl up to their old quarters. But perhaps the most effectual thing is fumigation; it does not hurt the plants in the least, and the smoke penetrates to every part of the plant. I at one time used to be afraid to use tobacco for this purpose, but I no longer fear it. As to woolly aphids, he has ceased to be the bugbear he used to be. It is not found to be injurious to the roots, but when it is found clustered round the collar of the plants it should be removed by the finger and thumb. When all these minutiae have been attended to, and the frames have

been well cleaned, and if necessary painted, the plants should be removed to their winter quarters, facing the south. Water must now be given sparingly, depending on the weather; if that is bright and sunny they will require it oftener than if it be dull and cloudy. Nor is it well to water all the plants indiscriminately; it will be seen which require it most, and it is better to take a little pains in this matter than to give an over-supply that may injure the plants. Air should be given whenever the weather is at all favourable, and when the nights become cold mats should be provided to cover them; but above all things avoid damp and drip from the lights. Treat the plants as hardy, but keep them from frost, not so much for the sake of the plants as for the bloom, which suffers from it.

CARNATIONS AND PICOTEES.—The season has been a peculiar one for these plants. My own small collection did very well, but the grass made growth so late, and the bloom was so late also, that the layering was postponed to a much later period than usual, it being far into September before even my small collection was finished. At the same time, the grass looks unusually healthy. It will now be time to take off such layers as are rooted. They should be either potted singly or in pairs; the compost used should be simply good loam, and a little coarse sand or grit to keep it open. The advantage of potting them thus is that when planted out the roots are very little disturbed, and growth goes on at once. Here too, as with the Auricula, damp is the chief enemy to be avoided. This causes spot on the leaves, and impedes the well-being of the plant. When potted they should be placed in a frame and kept close for a few days. They should then be removed to a frame or frames placed facing the south, and water should only be given when actually required. Air should be given on all suitable occasions, and indeed until frost sets in the frames may be kept open night and day. I may here say that I have had a most satisfactory bloom, and owing to the kindness of Mr. Douglas and Mr. Laken have been enabled to enjoy the sight of some of the newer varieties which I should otherwise have missed.

GLADIOLUS.—Towards the end of the month some of these may possibly be ready for lifting, although I do not think that there is need to be in a hurry about them. Some advocate the lifting of them when the foliage is quite green, but we do not do that with other bulbs, nor think it is advisable with these. The French growers say that November 5th is the proper time for lifting, and if they, with their drier autumns, think so, surely it ought to be much more so with us. There is, of course, a great difference even in our islands, and in late districts it may be necessary to loosen the roots by slightly raising them with a fork, but in the more southern parts this is not necessary. I have never had a finer bloom, although very late; and indeed have now, September 29th, a stand of twelve in my hall, with which I should not be afraid to enter the lists with any amateur, and I have had less signs of disease amongst them than I ever remember, so that, on the whole, I am inclined to think that they prefer a wet to a dry season. When they are taken up they should be carefully dried and put away in some place where frost cannot reach them.

PANSIES.—As I grow my small collection of these in pots I am now taking the old plants from the open, where they have been growing since the spring, and am dividing off and potting them for the winter. I find this to be, perhaps a lazy, but a good plan, sufficient for my purpose. Perhaps were I an exhibitor I should be more careful and strike them from cuttings, but plants treated as I do mine give me a beautiful bloom, and the flowers are as large as any I see at exhibitions. I grow none but Fancy varieties; indeed the old Show varieties seem pretty well elbowed out now, and for one Show there are fifty Fancies grown, and no wonder, they are so much more varied in colour and more robust.

RANUNCULUS.—The Persian varieties will only need to be looked over in order to see that there is no damp about them, which is very injurious to their well-being; indeed, if it gets at all a hold on them it is fatal, but it will be time in the early part of November to plant the Turban varieties, which are not so much grown as they ought to be. They will grow in any good garden soil provided it is not too heavy, and being perfectly hardy they give in early spring a large quantity of beautiful flowers.

TULIPS.—If the ground is in good order any time early in November is suitable for planting these bulbs. There seems to be a prospect of the revival of the fancy for them in the south. In the north they have always held their own, and I can remember when they were largely and well grown in the south. I remember going to see Groom's collection at Walworth, and those of amateurs at Sevenoaks and other places, but now, "None, alas! so poor as to do them reverence." Yet are they most gorgeous and beautiful flowers, and although a great fuss was made about them in former days, it is very questionable whether it was all necessary. There is one thing that intending growers should remember, that it is a mockery, delusion, and snare to look to Dutch growers for what we want. I had a collection from a very eminent Dutch firm, and I may safely say that there was hardly one amongst them that would come up to the requirements of an English fancier as what a rectified Tulip is—stained bases to the petals, the colours right down to the bottom, pointed and ill-shaped flowers were all too common, so that I have been trying to eliminate them ever since, the principal difficulty is to know where to buy them.

Of Roses and Chrysanthemums I have said nothing, because such ample directions are given from week to week in the Journal that it is unnecessary. Rose growers will now be in a wild state of excitement, making alterations, getting in new kinds, and clearing out those

which have been found wanting; indeed, altogether this is a busy time with the floriculturist. The fine weather we have lately had has been beneficial, but I fear it is not likely to last long now, therefore we must

attracted considerable attention from visitors. The central florets are of a dark bronzy hue, the broad spreading or drooping rosy florets being of a purplish crimson colour, very distinct and quite a relief from

FIG. 38.—*RUDBECKIA PURPUREA*.

make use of every fine day that we can, and get through our work. —
D., Deal.

RUDBECKIA PURPUREA.

A HANDSOME autumn-flowering Composite, which from its bold habit and large flower heads is most conspicuous in gardens either in separate beds or associated with other plants in borders. Masses, however, have a particularly good effect, and at Kew this season it has

the prevailing yellow shades amongst the autumn flowering Compositæ. It grows to the height of 3 or 4 feet, succeeds in deep well-drained soil, is quite hardy, and a perennial.

LATE PEAS.

SOWINGS of Telephone Peas which were made on the 15th of June last, and Ne Plus Ultra and Champion of England sown a week earlier

in drills 3 inches deep, from 8 to 10 feet apart, and running north and south, are now, as they have been for some weeks past, yielding abundant supplies of large, handsome, and well filled pods. The haulms were earthed and sticks supplied in due time, the supports being 6 feet high from the ground, and a good mulching of manure was then laid on each side of the ranks. Subsequently, owing to the weight of the crop, long Bean sticks were placed longitudinally on each side of the rows at 5 feet from the ground and secured to a series of upright sticks of a like thickness driven into the ground on each side, and with cross-ties made of tar string. These necessary supports have served a double purpose—namely, in the first instance in supporting the heavily laden haulms in an upright position, and now in supporting the no less heavily burdened haulms which overhang the longitudinal supports 3 or 4 feet on either side. This is the result of the wet season. The haulms have kept on growing from the time they started into growth. They are growing, flowering, and podding still, and will continue to do so until cut down by frost. Growers should note this.—H. W. WARD.

THE PEACH.

[A paper read by Mr. T. Francis Rivers at the meeting of the Horticultural Club, 'Hotel Windsor,' October 9th.]

THE origin of the Peach, like the origin of species, is so far removed from all our means of arriving at the truth that it is not necessary to make it a subject of discussion. It is sufficient to say that it is probable it was introduced into Europe from Asia about the time of the Emperor Augustus, and it was introduced into Greece by the Romans; the name *Persica* indicates the country from which the Peach is derived. It is said by some French authors that a variety of the Peach was grown in Southern Gaul at a very early period. There is, however, nothing remarkable in this fact, as the Mediterranean was traversed by Syrian mariners before Rome had attained to imperial power, and the seaport of Marseilles being a trading centre of great importance, there would be nothing strange in the fact of the introduction of Peaches from Syria into Gaul. We know of course that the relations of Syria and Persia had been very intimate from very ancient times, the Book of Esther showing that an important colony of Jews was established there. The transfer of the fruit in a dried form would account for its introduction into Palestine, and as the Peach varies almost more than any of our domestic fruits from seed, no doubt plenty of sorts came rapidly into general cultivation. To this day certain districts of Syria abound with Peaches and Nectarines. An old friend of my father sent him some years since some score or more of Peach trees which had been raised in the gardens near Aleppo. These were received with the native soil clinging to their roots; all these were seedlings, and bore fruit of different degrees of excellence, some being Nectarines of the Stanwick type, and some very good and sweet Peaches. A thirsty traveller would no doubt go into ecstasies about them, but when tested here in company with cultivated varieties they were good but of no particular excellence. The sweet kernel, which is a distinguishing characteristic, is of course of no consequence, as one would hardly crack a Peach stone with the teeth, and the labour of extracting the kernel with a hammer would not be repaid by the result.

There seems to have been an uneasy feeling among some of the ancient doctors that the Peach is not a wholesome fruit. I can understand that this theory was founded on something like a hard fact, for some of the seedling Syrian Peaches and Nectarines were so bitter as to be uneatable, and the strong flavour of prussic acid suggested their unwholesomeness; in fact, I should have been very sorry to have eaten one of these bitter fruits, a very slight taste was convincing. Assuming that Persia was the native home of the Peach, it seems to have spread both to the east and west with equal facility, for the Peach is so well established and so universal in China that its introduction through the Central Asian highways of commerce must have taken place at a very early period.

The Peach seems to have attracted popular attention in a singular degree in China. Its history has been wreathed with legends more or less interesting, and as it can be cultivated without the assistance of walls the Peach orchards when in flower are wonderfully attractive, the trees being laden with pink and white blossoms, which are used for decoration in the houses of the wealthy and luxurious Chinese. It is not abundant enough here to be used as a decorative flower, but there is no doubt if it could be gathered from trees as children gather May, it would soon become popular. In the "Leaves from my Chinese Scrap-book," by Frederick Henry Balfour, it is stated that three sorts of Peach trees are grown by Chinese gardeners—the dwarf, the shrub and the full sized trees, of these the dwarf is the most highly prized for the beauty and perfume. Of its blossoms which are remarkable for their size and colour, and are divided by Chinese florists in eighteen different species. Some of these are the varieties which electrified the gardening world

when introduced by Robert Fortune. As they are not hardy enough to be grown in the open air they have not retained their original popularity.

The shrub grows to the height of 4 or 5 feet, is common in the Imperial gardens, where it is planted on the margins of pools and acclivities of rockwork, which form a prominent feature in Chinese artificial landscapes. This is, of course, our flowering Peach. If our climate were not so cold in the spring there is no doubt the Peach would be a popular ornamental flowering tree, but a biting east wind does not conduce to the admiration of any out-of-doors product; but I can quite understand the delicious effects given to the early spring in China by the abundant and delicate colouring of this pretty tree. One of the Chinese historians has described in glowing language the delight of seeing the villages connected by gigantic wreaths of Peach trees, dotting the plains as far as the eye can reach.

The third sort is the full-sized tree, and is cultivated for the fruit, which I have always heard is handsome and poor in flavour. There is much diversity in the shapes and colours of these fruits, some being spherical, and one variety a curiously oblate spheroid, which we call the flat Peach of China, and which is no value except as a curiosity. The Peach is said to have been established upwards of 2000 years in China (this is a very moderate estimate of Chinese time), and was presented to the Emperor Wu-Ti of the Han dynasty by foreign ambassadors. It was held in so much esteem that the fruit or plants formed part of the tribute paid to the Imperial government by foreign nations. It is also one of the emblems of longevity and marriage:

"When the Peach tree flowers,
The bride with order rules."

Here, I think, where the Tarragon grows, the grey mare is the better horse. A Peach garden was the scene of one of the most celebrated events in Chinese history, where the oath of brotherhood was taken by the three heroes who played so important a part in the historical romance of the "Three Kingdoms." There are many interesting details connected with the Peach in Chinese literature, to which it is not necessary to refer. The Chinese gardeners have an infallible receipt for the destruction of the insects which infest the Peach. This is a decoction of pig's head, poured on the trunk and into the roots, and they also say the best manure for the trees is snow. From China many of the Peach trees in Australia were derived. Residents, however, say that the Peaches are woolly and insipid, and always full of grubs.

The Peach appears to have been known in England in the eleventh and twelfth centuries, as we read that King John died of a surfeit of Peaches and new wine at Swineshead Abbey. It is very probable that it was known to King Alfred, as his tutor resided for some time at the Court of Charlemagne, who was a cultivator and admirer of the Peach. It is recorded by French historians that he ordered a list to be compiled of the varieties grown in his garden. In the seventeenth century the fruit appears to be very generally cultivated, as both Philip Miller and Batty Langley, early in the eighteenth century, give lists of some forty or fifty varieties, many of the sorts named being still familiar to English fruit gardens.

No English historian will ever be able to point with pride to his native villages being wreathed with Peach orchards, but there seems little doubt that before many years have elapsed the railways will be lined with glass houses, under whose sheltering protection more good Peaches will be grown than either Chinese or American orchards have ever produced. No fruit suffers so much from bad cultivation and over-production as the Peach. Excessive cropping means loss of flavour, and good cultivators need never fear competition. A bad Peach is only fit for pigs. The fruit has no economic value in the sense of the Apple and the Plum. As a preserve it is not equal to the Plum, and it cannot be stored for future consumption like the Apple. In this country it must therefore be a fruit of luxury, requiring skill and capital for its cultivation, which must be carried on either on walls or in glass houses. Very uncertain crops are, however, obtained from unprotected walls in our climate, and my own experience has been gained for the last thirty years from glass houses, during which period I may say that I have never known a failure.

When the cultivation of Peaches in pots was systematised it became possible to test the several varieties, both of the Continent and of England, which had been hitherto known by name only, and a collection was formed, including as many distinct varieties as it was possible to obtain. I remember being much interested by the precocity of some of the sorts, the "Avant Pêche Rouge" and the "Double de Troyes" being ripe in the middle of July, the "Early Anne," dedicated to the memory of Mrs. Anne Dunch, ripening at the end of the month

Although of little value as fruits, I thought they might prove valuable in imparting precocity to the later and better Peaches, and being young and curious I amused myself by mixing the pollen of the early and midseason varieties, preserving and sowing the stones of the fruit so treated. When the first batch of seedlings fruited, consisting of some two or three hundred trees, my father and myself were much interested in observing the curious diversity exhibited. Whether or no the mixture of the varieties caused this divergence, the appearance of early Peaches was at once an established fact, and in rapid succession came the "Early Beatrice," "Early Louise," "Early Rivers," giving an abundance of fruit in the orchard house during July, a month hitherto barren of any but worthless sorts. With the advent of the "Stanwick" Neectarine an entirely new race, both of Nectarines and Peaches, was created, the rich flavour and size of the Syrian fruit imparting a totally different quality to the progeny of the ordinary Peaches and Nectarines, and to this mixture I owe the Lord Napier Neectarine, for although this was raised from a Peach, there is no doubt but that it inherited the Stanwick blood. Most of the seedlings raised from this race have vigorous growth and deep green sickle-shaped leaves.

In 1874 I received from Messrs. Capps & Son of Mount Pulaski, Illinois, two Peaches which they affirmed were the earliest to ripen in the United States; these Peaches were the Alexander and Amsden June. I confess that I was entirely incredulous, but I had the plants potted, and in due time they produced and ripened fruit; to my great pleasure it matured in a cold orchard house six days before the Early Beatrice. The Alexander, although slightly clinging to the stone, is a Peach of high quality in every sense; but the Amsden June, ripe almost on the same day, is slightly bitter and a clingstone. I did not think it necessary to cultivate two varieties so closely allied, and I preferred the Alexander. I see, however, that on the Continent the Amsden June is selected as being the superior. I cannot help thinking that in some cases the two varieties have become changed, a very easy matter, as they are so much alike. "Alexander, Waterloo, and Hale's Early are three very valuable early Peaches, and very distinct; the foliage of all is easily distinguished by the expert, the leaves being very bright and lanceolate, and the wood deep in colour. Although the Alexander and Waterloo are earlier than the Early Beatrice and Early Louise, yet the hardiness and fertility of these two English sorts will always keep them in general cultivation. I am almost inclined to think that the Early Beatrice, if grown in the open air after protection during the spring, would give a reasonable profit. I have seen it ripen on neglected bushes in the last week in July out of doors, the colour of the fruit being so bright that I thought some Poppies had been overlooked.

The midseason Peaches are of course well known to all gardeners. The great tribes or races are the Noblesse, Grosse Mignonne, Galande, and Madeleine. From these types hundreds of varieties appear to have been raised from seed and named. The Noblesse is probably derived from the Madeleine Blanche, and reproduces itself frequently from seed. The Grosse Mignonne is one of the most popular Peaches in France. Under this name André Leroy enumerates no less than fifty-seven synonyms. There is no doubt that this is one of the most excellent of Peaches. According to this French author it has two centuries of existence. La Quintinye, in 1680, declares that the Mignonne is the finest Peach in cultivation, very large, velvety and round, melting and exquisite, but sometimes flat and insipid, a fault from which no Peach is entirely free under certain conditions of soil and culture. In England this Peach has obtained so much popular favour that it is encumbered with synonyms. There is no doubt that it is worthy of the extended cultivation it has received, and it is to be regretted that the season of ripening cannot be enlarged; the multitude of seedlings which have been raised from it have not, however, produced this desirable result. The Early Grosse Mignonne ripens sometimes in advance, and the Belle Baucé or Mignonne Tardive somewhat later, but the few days of difference are not of any great importance. There is a variety, said to be Grosse Mignonne, with small flowers, which I understand is sometimes sold by continental growers. This is a false Mignonne; the true Grosse Mignonne has large, clear brilliant flowers, and the leaves have globose glands.

The Galande is another distinct race of Peaches, which is also encumbered with synonyms both in England and France. It is distinguished from the Grosse Mignonne by the intensity of the colour of the fruit. When exposed to the sun in a warm season the skin becomes almost black, and one of its synonyms is Noire de Montreuil. It is perhaps harder than the Grosse Mignonne, and for this reason it is cultivated very extensively in the Peach gardens of Montreuil, and is the principal market Peach. The flavour of the fruit, when thoroughly

ripe, is very good, but visitors to Paris sometimes complain that the price is excessive, and that a franc a piece for hard and dry fruit is too much, the fact being that they are gathered long before they are ripe. The flowers of the Galande are invariably small. The Madeleine Rouge is the prototype of our popular Royal George, which again seems to be the sport of name-givers. The English sort under this name is so well established that it can be easily identified. The flowers are small, and the leaves serrated. The fruit is of the highest quality, but the excessive tendency to mildew renders this sort difficult to cultivate, as there appears no remedy for this disease. The Red Magdalen and Madeleine de Courson, which seem to have been very mixed with the Royal George, have large flowers and are glandless. I am responsible for the introduction of many varieties of Peaches, but I cannot say that I have ever studied the interest of the wall cultivators. Wall cultivation, unless in certain very favoured districts, appeared to me to be a weary waste of labour, and my object has always been to provide the orchard house with fruit from day to day, ranging from July to the end of September, after which date no reasonable man need desire Peaches or Nectarines.

In September after the Royal George we have the Barrington, claimed by the French as a synonym of the Chanceller; the Walburton Admirable, which is evidently a seedling from the Noblesse; the Late Admirable, which is also claimed by French pomologists as a synonym of the Bourdin. The orchard house has, I am glad to say, introduced a new race of late Peaches; these are—Princess of Wales, Lady Palmerston, Golden Eagle, the Neectarine, Sea Eagle, Gladstone, and Osprey, all of which fruits in the orchard house properly grown are far superior to the Late Admirable, Chanceller, Gregory's Late, Desse Tardive, or any other so-called October Peaches. There is a variety of the Peach which has never been very popular in England, but which is used in the south of France for stewing; this is the Pavie, the fruit being large and heavy, with tough and tasteless flesh, and a skin as disagreeable to the touch as cotton velvet. This is the Melacoton of the Spanish (Anglicé, Cotton Apples). In the soft Provençal tongue it is Mirecoton, or Mirlecoton, and in the United States, where the fruit seems to be popular, it is ingeniously transformed into Malagatune. If these Peaches could be grown out of doors like Pears or Apples they might make a pleasant addition to the dinner table, but they are not worth either the time or cost of glass or wall culture.

Since the introduction of the Stanwick Neectarine a great advance has taken place in this smooth-skinned brother of the Peach. Some few years since the Elruge and Violette Hâtive were the principal sorts grown, we have now a more extended range. These ordinary varieties of Nectarines, unless very skilfully and exceptionally grown, are small and insipid. The green-fleshed sorts have not been considered as equal in flavour to the orange-fleshed kinds. I think, however, this is no longer the case, the intermixture of the Stanwick race having imparted a quality of flesh differing completely from the older sorts. This is exemplified by the Victoria Neectarine, which was raised by my father, and is the result of a cross between the Violette Hâtive and the Stanwick. This is a very delicious and distinct Neectarine, but it ripens too late for walls in our climate, and must, therefore, be grown under glass to be enjoyed in perfection. The early sort, Lord Napier, I believe inherits the Stanwick blood, although it came from a Peach. This Neectarine begins a series of fruits which last through August and September, divided into two distinct types, the orange-fleshed and the green-fleshed. There are now many important varieties of the former, and I venture to say that the better known they are the more popular they will become, the principal sorts being the Rivers' Orange, the Pitmaston, Humboldt, and Pine Apple. These ripen generally in the order in which they are placed. The most decided success of late years in seedling Neectarines is the Lord Napier, ripening fully ten days in advance of the Hunt's Tawny, a Neectarine valued for its precocity, but otherwise of no merit. In Peaches and Nectarines, as in all other fruits, I hope we shall cease to place a fictitious value upon varieties because they happen to be old and historical. It will be much better, both for ourselves and for others, if we can improve the standard of flavour and merit. This can only be done by the judicious raising of seedling fruits. I have tried with varying success for many years, but considerable improvement is still desirable both in early and late Peaches. The failure of flavour attributed to the latter, however, appears to me to result from the fact that the tree, unless kept in a gentle warmth, is unable to complete the ripening. For this reason I think that the late sorts should be grown in a house devoted especially to them, so that the necessary heat should be applied. This continual heat is injurious to those sorts which have ripened their fruits

and desire rest. As late Peaches have a high value in the market, the extra expense is fully repaid to the cultivator.

The various methods of cultivating the Peach would require another paper, which I hope may be furnished at another meeting. The subject will be one of great interest and value, as I venture to think that we are still only on the threshold of Peach cultivation in this country.

RESTORING ROSES TO HEALTH.

My recent remarks were directed to Roses grown in pots and planted out that were subjected to early forcing. I never attempted recruiting unhealthy plants outside, when once they are thrown out. I should do the same with unhealthy forced plants. If they are left until they are too far gone, it is useless to attempt to do anything with them. But the strain of forcing will in time weaken plants, and if they are operated upon as soon as they display signs of exhaustion, fresh soil and a year's rest will often restore them to health and vigour.

SPORTS.

It is pretty clear, I think, that some Roses are much more liable to sport than others, the same as many other plants. *Merveille de Lyon* was in the market before I noticed it produced on a plant of *Baroness Rothschild*. For several years this plant has continued to yield flowers of both varieties. One half of the plant has flowers of the former and the other flowers of the latter. Both are beautiful Roses, and would be more highly appreciated if they possessed fragrance. Scentless Roses ought to be discarded, they are no better than *Camellias*.

ROSE THE BRIDE.

The *Bride* is a stronger grower than *Niphetos*, and in some respects a fuller and better Rose. In growth and the construction of its flowers it closely resembles its parent, *Catherine Mermet*. The greater number of petals in the flower than *Niphetos* possesses is in favour of its lasting longer, but the flowers have not the pure whiteness of *Niphetos*. The greenish tint, however, is not objectionable in either wreaths or bouquets. We have lately had occasion to use it for these purposes, and good full flowers are lovely. It will never supersede *Niphetos* in my opinion for market purposes, for although it is a stronger grower it does not flower so profusely; in fact it possesses the character of its parent in this respect in a marked degree.

ROSE HER MAJESTY.

This seems to be a shy bloomer. I have only two or three plants, but they have not yet produced a single bloom. They have grown strongly this year, and were the first in the garden to be attacked by mildew. I had hopes, judging from its thick leathery foliage and robust growth, that it would have been proof against this parasite. —W. B.

DRESSING ROSE BLOOMS FOR EXHIBITION.

MR. W. R. RAILLEM, page 287, has not referred to this matter too soon, and certainly his dispassionate method of treatment is most commendable. The question cropped up a short time since at the last Show of the Royal Irish Horticultural Society at Dublin, and the blooms shown by Messrs. Dickson of Newtownards were sought to have their size and beauty minimised by saying they were "dressed." A distinguished amateur hearing this buzzed about took my arm and said, "Come, Murphy, let us see how Dickson's Roses are said to have been spoiled." We went carefully through them—two forty-eight stands, I think—to see how many would wear the unnatural contorted appearance we heard of, but except *Madame Eugénie Verdier*, and if I remember right, *Caroline Durdan*, not one seemed otherwise than they might have been cut off the stem, and those two would be passed except you were searching for evidence. But is not the dressing of *Carnations*, *Dahlias*, *Chrysanthemums*, &c., permissible, especially in a bad season? —W. J. MURPHY, *Clonmel*.

RECOLLECTIONS OF ROSEBANK.

ROSEBANK is the residence of E. Mawley, Esq., the well-known and popular junior Secretary of the National Rose Association. Arriving from Euston at Berkhamsted, and having passed the interesting remains of its once renowned castle, a house appears reproducing the well-known Croydon wonders of wind and rain-gauge, while the grounds are full of other gauges of various mysterious meteorological appliances. There is no such private observatory in the kingdom, but what is more to the point there is no such highly scientific scene of Rose-growing, and desire to inspect this strongly added to the claims of friendship. Here are 1000 Roses in the highest state of cultivation. A field of half an acre contains them, excepting a few Teas on a south wall in the adjoining garden. It is divided into two parts by a lawn tennis court, and has narrow strips of turf between the long narrow beds. These contain two rows of thirty-five each, this arrangement being better than any other for getting easily at each plant, all Rose

bushes, and in a high state of excellence, the wood for next season being strong and robust.

The Teas, about 200 in number, were even finer than the H.P., and perhaps the most striking of all were a few high-class Teas on 3-foot standards. They were but one year old, and the heads come larger than is mostly attained in three years. I am still of opinion the standards are not sufficiently used nowadays, and the finest blooms of all come from maiden standards. The cold wet season, though fatal to Mr. Mawley's hopes up to June of very first-rate exhibition blooms, has done wonders for the growth of his *Maréchal Niels* against walls, which give the highest promise for next year. Side by side with these were two W. A. Richardsons as large and bushy as if they had been *Gloire de Dijon*, although quite young plants.

It was interesting to hear that Mr. Mawley considers *Ulrich Brunner* as the best H.P. It is so good all round—colour, size, magnificent growth, handsome foliage, and freedom from mildew. Her Majesty in this latter respect appears rather the opposite. The Tea beds, on Mr. George Paul's system, were considerably above the level in the middle. On herbaceous borders and giant *Chrysanthemums* coming on I may not enter, as Mr. Story says:—

"For, O my Rose, my frank, free-hearted,
My perfect above all conscious arts.
What are others beside thee? O Rose, my darling!
To thee I have given my heart of hearts!"

—A. C.

ROSE GLOIRE DE DIJON.

THIS is once more asserting itself as one of the finest autumn blooming Roses in existence. During September very fine blooms were obtainable both from plants from walls and also in the open border. It is largely used by cottagers in many districts for training up the front of their houses. It is one of the few varieties of Roses which will thrive and flower on a northern aspect.—M.

THE MANETTI STOCK.

If it should be of any interest to record the opinion of another Rose-grower, who has also exhibited, on the question of *Manetti* as a stock for Roses, I should like to say ditto to Mr. Pemberton, on page 312. *Olivier Delhomme*, a very beautiful Rose, is, on *Manetti*, an impossibility.—T. W. GIRDLESTONE.

It is, I think, quite possible that Mr. Murphy saw many thousands of old Roses on the above stock when visiting the home of the celebrated North of Ireland Rose at Newtownards recently. The last time I visited the nursery there was in August, 1886. There was then an enormous quantity of old Roses carrying such massive blooms as I have never before or since seen except in the Messrs. Dickson's stands at the Dublin Exhibitions. That the soil at Newtownards is peculiarly adapted to the *Manetti* stock no one who has seen the Roses there can deny. Here, however, they will not thrive; we have tried them in every fertiliser, and always with the same result—failure. Those on the *Briar* do exceedingly well. Two years ago we produced a hundred of each. More than two-thirds of those on the *Manetti* are gone over to the great majority, while of those on the *Briar* there are but eleven dead. Soil, I believe, has a great deal to do with Roses as regards success or failure on the different stocks. In the neighbourhood of *Clonmel* magnificent Roses will be found in their season growing on the *Manetti* stock. On one occasion when in that locality I saw some in Mr. Murphy's collection that would have been highly creditable in the stand of cut-blooms from any professional Rose grower. Doubtless Mr. Murphy will inform Mr. Gilmour the size of the blooms I saw, also the age of the plants, as I ascertained neither of these facts.—R. WELLER.

I HAD no intention of embarking in a controversy on this subject, and may say I quietly stood aside until my name was brought prominently forward by two writers in your Journal. Mr. Duncan Gilmour, jun., is evidently determined to give the *Manetti* no quarter, and to strengthen his arguments quotes from page 20, "*Rosarian's Year Book*, 1888," that I favour the *Briar* cutting, but he altogether ignores what I wrote about the *Manetti*, page 19. If Mr. Gilmour cannot grow Roses on *Manetti* others do. How can he get over the fact that two of the most celebrated amateur exhibitors (I refer to Mr. R. N. G. Baker and Mr. Jowitt), year after year contested for the championship (during that time no one could approach them) with Roses grown on *Manetti*? The former gentleman, writing in 1879, says that all the blooms he exhibited that year were grown on cut-back plants on *Manetti*, most of which were five years old. Probably if Mr. Baker had any Teas in his stands they were cut from *Briar* stocks, but singular enough this year Mr. Baker again wins the champion trophy, and this time there was not a single Tea Rose in his forty-eight. Perhaps he will kindly tell us where he had those splendid blooms from, *Manetti* or *Briar*? I once had the pleasure of spending a few days with Mr. Jowitt at the Old Weir, Hereford, at a time when he was heads and tails with Mr. Baker as to who should be first; his Roses were all on *Manetti*, and many of them three or four years old, and splendid they were. Again, an ex-amateur champion wrote me last spring, that the strongest plants he had in his garden are "old" ones on *Manetti*. It is no argument to say then they must be on their own roots. Does that in any way damage the value of the stock on which they were budded? The secret of success is by careful study to find out the most suitable stock for the various kinds of Roses. As a rule, all the strong-growing Hybrid Perpetuals, Moss, and summer Roses, also those of robust habit, such as *Baroness Rothschild*, *Merveille de Lyon*, &c., &c.,

do first-rate upon Manetti, yet for choice I prefer the Briar cutting to seedling Briar, Manetti, or any other stock, as I have never found it fail me whatever kind is worked on it. Mr. Gilmour is wrong in supposing nurserymen have no quantity of plants excepting maidens. I have something like 4 acres of them ranging from two to eight years old, from which I cut many thousands of blooms every morning during the summer months, and very many are used at the early shows before the maidens are in flower.—BENJAMIN R. CANT.

I DO not desire to continue the discussion on this subject further than to ask your permission to point out to Mr. D. Gilmour that when he says, "I could go on pitching in the Manetti over several sheets" (261), and my reply (287), that "I am sure any reader who has been a student of his racy style and fertile imagination will take this readily for granted," does bear another interpretation besides that of impugning his veracity. I meant to write in the same good-humoured vein as he did; and you must permit me to say I extremely regret if I have annoyed him; as he seems to think I have made "insinuations" against him. As to his queries about my "limited" number of Roses, I have already answered them by anticipation; and as I mean to lift them within the next few days I shall know how the roots grow, or from whence they come—none on the Manetti after eight years is dead. The soil is a strong limestone loam; Messrs. Dickson's seems much lighter.—W. J. MURPHY, *Clonmel*.

A TWIN ROSE.

I ENCLOSE a double Rose bud, two flowers on one hep. I am aware that there is nothing very unusual in it in itself, but it is remarkable as springing from a shoot of the striped sport mentioned in No. 2083, and from the same portion of the plant as produced the pink sport, and would seem to point out an inherent tendency in the strain to vary in every possible way—colour, growth, shape, and strength.—DUCKWING.

[It is an example of fasciation, two buds and stalks having become combined in an early stage.]

FIXED TEMPERATURES FOR VINES.

MR. YOUNG said, "We have no fixed temperature, but work by the 'feel' of the pipes, which are kept comfortably warm." I said on page 260 that I agreed with him. For years I have worked on the principle that he advocates, but I have invariably found that young men took a good deal of drilling before they could thoroughly grasp the matter and carry it out properly. Once this is mastered—and it should be done by the dullest pupil in a week—it is the easiest and safest method of maintaining the necessary temperatures for conducting forcing operations under glass. I do not believe that one man in a hundred would have a desire to return to the keeping of his houses at fixed temperatures after he has once been thoroughly initiated into regulating the temperature by external conditions. "Fixed" temperatures result from breathing upon the thermometer and other kinds of deception before the chief enters, so that the mercury shall be "right" whether the house is or not. Even in following what we may call a natural system, it is necessary to have a stated temperature, especially for the guidance of the inexperienced; but in doing so a wide margin should be given, often 15° in the night temperature. But it is needless to fix temperatures for the inside unless they are arranged to allow for variations externally. For instance, if we wanted a house, say 55°, it would be maintained at that temperature if the thermometer stood at freezing point outside; and if it continued to fall, the temperature inside would be allowed to fall to 50°. If it stood 45° to 50° outside, it would be madness to try to keep any structure at 55°. On such occasions the pipes would be kept gently warm, even if the house stood at 70°.

This is the principle upon which I have worked, and I have found it to be more satisfactory than trying to keep the temperatures at a fixed degree, whether mild or the reverse, without the slightest deviation being permitted. I nearly killed a house of *Odontoglossums* once by trying to keep it at 45° where the thermometer was hanging. Three parts of the house was at freezing point. Most of the plants took two years to recover, and some died. It taught me a lesson I have never forgotten. The maintenance of fixed temperatures was one of the mysteries of gardening for many years, and it will be a long time before it is obsolete.—WM. BARDNEY.

CATERPILLARS IN THE PAST SEASON.

COMMENTING upon a circular on the caterpillar pest, which has just been issued by the Agricultural Department, a daily contemporary refers at some length to the subject in an article from which the following remarks are extracted:—

The past season, apart from the drawback of continuous cold and wet, was disastrous to fruit growers, owing to the swarms of caterpillars which attacked their orchards. Apples, Pears, Plums and Filberts were rapidly stripped of leaves, so that no sight was more common during the summer than to see trees almost bare of leaf, instead of being covered with blossom or with fruit. When the flower buds and the young leaves began to expand, legions of caterpillars—little, light, unsightly things—seized on them, until in a few days many of the usually prosperous plantations in parts of Kent, Hereford, Worcester, and other counties, looked as if a sirocco had passed over the country, scorching every green thing in its course. The result was, of course, a scanty crop in the blighted districts; and (what is quite as serious) the

trees, it is feared, have been affected, so far as their bearing powers are concerned, for next season. The reason is plain. The caterpillars which worked such woe were the larvæ of various small moths, which are already laying their eggs, and will in the second generation multiply a hundredfold, if their numbers are not diminished either by man, or birds, or the weather. The two latter contingencies are not to be depended on, so that the farmer and fruit grower must now bestir themselves to put in force the preventives which lie ready to their hand. But in doing so regard must be had to the habits of the caterpillars, or rather of the moths of which they are the intermediate stages. The chief offender was the Winter Moth, though the Pale Brindled Beauty, the Mottled Umber, and a few other species with a similar life-history shared in the mischief. As the females of these moths are practically wingless, they must remain not far from the spots where they have passed their ehrysalis, the mummy or cocoon-like stage, and hard by the trees upon which they live during their caterpillar existence. There was, however, a second group of moths busily at work all summer, or spring, which must be checked in their costly career by means in accordance with their habits. The Lackey Moth, one of the pests of Oaks, Elms, and Beeches, and especially of Apple trees, the Ermine Moth, and the Figure-of-eight Moth, are types of this section of the orchard owners' enemies, though they were not quite so destructive as the first-named group. The females of the second group of moths can fly, and some of them lay their eggs upon the twigs and spurs of fruit trees, where they remain until spring.

In the case of the Lackey Moth, the Entomologist of the Agricultural Department tells us that its caterpillars change to ehrysalids under rubbish, grass, and clods near the fruit trees they have injured. Accordingly, to limit the family, it is necessary to destroy the progeny in these quarters, by brushing off the grass and weeds under the trees, and raking up and burning all rubbish. Lime and other caustic materials might also be usefully applied to the surface, as the ehrysalids do not burrow deep in the soil; while a preliminary digging and hoeing in cultivated ground, before the liming is put into practice, is likely to render the process even more efficacious. To throw finely powdered quicklime into the trees in winter during a damp fog, when there is just sufficient moisture to hold the lime up on every part of the twigs and spurs, might also be useful. This treatment applies excellently to mossy Apple trees, as it destroys the lichenous growth, which looks so picturesque and poetical, but in reality harbours all kinds of insects. It is nevertheless clear, owing to the free flight of the female of this group of moths, that it is more difficult to provide preventives against their raids than to apply remedial agents after they have begun work. But when the fruit grower has to deal with the first group his task becomes easier, and the results more certain. The moths being wingless and their habits therefore less wayward, all that is needful is to destroy them in the caterpillar condition, which terminates towards the end of October, by digging the ground around the trees, and applying lime and other caustic substances. Again, the female moths may be prevented from ascending the Apple and other trees, for the purpose of laying their eggs, by tying round the trunks and branches bands of cloth or ropes of hay dipped in tar or smeared with cart grease, or with one of the various compositions sold for the purpose. Oil cake or manure bags dipped in a mixture of softsoap, paraffin oil, or carbolic acid, in any of its various forms, are even better. In the United States and Canada—where for many years past the various State and Provincial Governments have bestowed much more attention on these matters than we have—girdles made of tin and stout line, well smeared with these substances, are fastened round the stems. Drenching the ground under the trees with water having paraffin oil in it, or applying strong liquid manure, dressings of quicklime, gas lime or soot, at some distance from the trunk, are the most approved modes of killing the ehrysalids before the perfect insect emerges from them.

In fruit plantations it is also possible to get at the ehrysalids by digging all round the trees in October, working in at the same time lime, soot and other substances of a like disagreeable character. This is especially necessary in the case of Filbert and Cobnut trees, round which it is not always practicable to place guards. Such trees, when badly attacked by the Winter Moth, should not be pruned until January, after the eggs have been deposited, and then the lopped-off branches should be burnt. At the same time the loose bark of Apple trees should be removed, and the stems brushed with softsoap, paraffin, or carbolic soap—a treatment equally applicable to Pear and Plum trees. In the circular nothing is even hinted at regarding the services which birds render to the fruit grower in keeping in check the insects which so seriously diminish his profits. It was, indeed, loudly affirmed this year that the wholesale destruction of sparrows by the Wirral and other farmers' clubs had not a little to do with the extraordinary increase of the other winged creatures. This, so far as sparrows are concerned, is, we think, a mistake. There is no doubt that in towns, where the sparrow—a graminivorous bird—cannot procure more appropriate food, it destroys aphides, cockchafer, and the like. Yet there is no denying the allegation that this bird is an indifferent friend of the farmer; and unquestionably, for every caterpillar it might devour in an orchard, it would ruin a large quantity of fruit. The Buff-tip Moth caterpillar is easily shaken from the Lime tree in showers; and in Germany, especially when the caterpillar is torpid in early morning, it is found that it is easy for three people to clear fifteen trees in a few hours of Pine Sawfly larvæ by simply jarring the branches. The small Ermine Moth caterpillars can also be easily shaken to the ground, and then dispatched; and cockchafer are sometimes shaken down, when they are speedily disposed of by pigs and poultry. The most effectual means, however,

of getting rid of all these insect pests is to prevent them from laying. This can be accomplished by smearing the bark with train oil, softsoap, or other disagreeable substances; though we fear that this, like a great many other preventives, is not, on the whole, so readily useful in large as in small orchards.

FLOWER GARDEN NOTES.

ZONAL PELARGONIUMS.—Frosts have greatly crippled the more tender bedding plants, and in many instances the work of breaking up the beds has already commenced. Although enough cuttings apparently have been struck to meet all the requirements of the garden, many of these may be lost during the winter, and it is advisable in this case, and imperative in others where an insufficiency of cuttings have been rooted, to lift and store a number of old plants. There are various makeshift ways of storing them, dry rooms, outhouses, and even cellars being utilised for the purpose. The surest method of wintering a sufficiency is to pack a number of plants closely together in either well drained boxes or in large pots, or they may be placed singly in small pots, the choicer varieties most needing this treatment. In any case the plants should be forked out of the ground, no attempt being made to preserve a ball of soil with the roots. Pick off the greater portion of the old leaves, shorten the roots considerably, and pack or pot firmly in any common soil. They may be stored in a dry light soil, the shelves or staging of an empty vinery answering well, while those in pots may be set on greenhouse or other shelves. Dry pits and frames, rooms, and outhouses may also be utilised for storing the plants. Give no water at first, and only sufficient subsequently to prevent shrivelling. A little frost such as benefits the fruit trees will not hurt them, but they must be protected from severe frosts.

TUBEROUS BEGONIAS.—These stood through a frost surprisingly well, only those in a low-lying position being crippled. Soon after frosts have disfigured them these Begonias ought to be carefully lifted with a small ball of soil and roots, and be packed closely in boxes of light and only slightly moist soil. They may be set in dry sheds or rooms, or in dry cool houses, pits, or frames, no water being given, and according as the tops die these must be removed, or the decay may spread to the tubers. Damp and frost are the greatest enemies to be feared, and much fire heat is injurious, causing premature growth. Autumn-struck cuttings and late-raised seedlings will all form small bulbs or tubers, and these should be gradually dried and kept cool and dry till the spring.

DAHLIAS.—When the frost spoils these they ought soon to be cut down to within 8 inches of the ground, and the roots at once lifted. The greater portion of the soil should be cleared from the tubers, and the plants be then stored in a shed stems downwards to dry. Before the tubers shrivel they ought to be packed closely in a single layer in boxes and well covered with nearly dry soil, or they may be set on the floor or bench of a dry shed and covered with soil. All they require is to be kept cool, dry, and protected from severe frosts. The commoner varieties, including the old Constance or White Cactus and the singles, generally have the most robust constitutions, and these may frequently be safely wintered in the open. If well established in a rather dry position all that is necessary is to cut them down to near the ground, and then well mound over with ashes or cocoa-nut fibre refuse. If a severe frost reaches the collar of a Dahlia this usually proves fatal, and for this reason either lifting or protecting must not long be deferred after the top is crippled.

CANNAS.—The strong clumps of these ought to be lifted directly the foliage is spoilt by frost, and may be wintered as easily as Dahlias. Some of the soil of the beds should be left on the roots, and after being dried somewhat, all may be set closely together in a shed or cool cellar and lightly covered with nearly dry soil. Warm, moist, and darkened cellars are unsuitable, but answer admirably when plenty of light and air can be admitted in all but frosty weather. In warm localities where the subsoil is of a gravelly nature, or in dry positions near shrubberies, Cannas may be left undisturbed and protected with a mound of ashes; but, as a rule, the safest course is to lift and store where frost or much damp cannot reach them.

SALVIA PATENS AND VERBENA VENOSA.—The former has done remarkably well this season, and in most years is very effective in the centre of large beds and also in mixed and ribbon borders. It is tuberous-rooted, and ought to be cut down, carefully forked out of the ground, and after being dried somewhat, be closely packed in boxes of soil and kept either in a house where drip cannot reach the soil, or in pits or frames. Kept on the dry side, only enough water being given to keep the tubers plump, and protected from severe frosts, every plant will push up numerous cuttings next spring, and which may easily be struck in gentle heat. Verbena venosa is fairly showy, very serviceable, and easily wintered and propagated. It forms long fleshy roots, and the old stems with these attached should be forked out of the ground and closely packed in shallow boxes of common soil. Even loose roots may be similarly treated, and all will keep fresh and plump in a pit or frame. Every short piece of root with one or two points may be converted into a plant next spring.

HERBACEOUS LOBELIAS.—These also have been very beautiful, a mass in the centre of a bed being most effective. The old stems may be shortened down, the plants forked out of the ground, and either potted or packed in boxes of soil. Being wintered in a cool house, frame, or pit, very little water being given, all will push up numerous young growths or suckers, and a larger stock of plants obtained by division.

SUCCULENTS.—A severe frost has caught a few of the choicest *Sempervivums* and *Echeverias*, but all have been lifted and stored for the winter. They require rather small pots or very little sandy soil to root in; must be kept very dry, and any decaying portions be cut out as often as necessary. A damp position, drip, and frost, prove fatal to them, and they ought therefore to be wintered, where possible, on dry shelves or staging in slightly heated houses. The common *Echeveria secunda glauca* may be very closely packed together in frames and protected from severe frosts, or in boxes in houses or frames. A large number may frequently be safely wintered packed facing outwards in a mound or bank of soil against a dry sheltered wall, being protected from snow and frosts with the aid of garden mats or other coverings. Sometimes they are bunched up like ropes of Onions and suspended in cool vineries or other houses, where they keep alive till it is safe to put them out in the spring.—W. I.

NOTES FROM GUNNERSBURY HOUSE.

THE well known gardens attached to the residence of H. J. Atkinson, Esq., at Acton, have long been noted for good management in every department, no one hobby being allowed to interfere with the well-being of others. Health, luxuriance, and cleanliness are conspicuous throughout, and it would be difficult to find in so limited a space gardening, in its many forms, so thoroughly carried out as it is at the above named place. The well-stocked kitchen garden, vineries that maintain a constant supply of highly finished Grapes, pleasure grounds abounding in choice and beautiful shrubs and delightful views, have frequently been fully described in the Journal, while the fine specimens of stove and greenhouse plants, which a few years since were exhibited by Mr. Hudson, will be remembered by many as the victors in numerous hard won fights. Large specimens are not grown now, but a good stock of Palms, *Dracenas*, *Crotons*, &c., of a suitable size for decorative purposes is still kept. The work of propagation going on continuously, and the excellent condition of the plants, unmistakeably indicate that they are in the hands of one who thoroughly understands their culture from the cutting to the specimen plant. My object in penning these brief notes is to draw particular attention to the exceptionally fine *Chrysanthemums* I had the honour of inspecting early in September, the majority of the plants being grown on the large-bloom system, three shoots to each plant, and although not grown for exhibition, many an intending competitor at the *Chrysanthemum* shows would contemplate the coming struggle with equanimity if he possessed such plants as these. They are tall, vigorous, and clothed to the rim of the pots with deep green leathery foliage, the wood being wonderfully hard and well ripened for such a season as we have passed through. This satisfactory state of ripeness in the wood is, I believe, due in a great measure to the fact that the plants are in smaller pots than they are usually met with; indeed it is quite a marvel how such large and vigorous plants could be kept in so healthy a state in the limited amount of root room allowed. The largest pots are only 9 inches in diameter, and yet I did not notice a single unhealthy leaf in the whole collection, which was one that any *Chrysanthemum* grower might be justly proud of.—H. DUNKIN.

LOBELIA PUMILA MAGNIFICA.

THIS is one of the best *Lobelias* that I am acquainted with. It is a good grower, of compact habit, and produces flowers of a rich blue in great profusion. Therefore it should have a place in every garden where masses of distinct colours are employed. But, owing to the plant being such a profuse flowerer difficulty is experienced in procuring the necessary complement of cuttings in the autumn, and on this account a dozen or two plants should be taken up at once with a little soil adhering to the roots. Shorten the latter back to the soil and cut the flowering shoots down to within a couple of inches of their bases before the plants are potted. Employ 4½-inch pots and a mixture of four parts light sandy loam and one of sweet leaf mould, the soil being made moderately firm about the roots. Place the plants in a frame or pit out of the reach of frost or excessive damp, water through a rose to settle the soil, and keep the plants close for a week or ten days until the roots have pushed into the fresh soil, when plenty of fresh air should be admitted on all favourable occasions. Keep them also on the dry side at the roots to prevent the plants starting into growth before being required for propagation in the spring. They should then be put in heat near to the glass to induce the plants making a sturdy growth, from which to strike sufficient plants for furnishing early in summer the number of beds allotted to it in the flower garden. The plants when put into heat should be kept moist at the roots.—H. W.

THE PROGRESS OF BOTANY.

(Continued from page 309.)

THE DARWINIAN THEORY.

THIS leads me to touch on the great theory which we owe to Mr. Darwin. That theory, I need hardly say, was not merely a theory of descent. This had suggested itself to naturalists in the way I have indicated long before. What Mr. Darwin did was to show how by perfectly natural causes the separation of living organisms into races which at once resemble and yet differ from one another so profoundly came

about. Heredity explains the resemblance; Mr. Darwin's great discovery was that variation worked upon by natural selection explained the difference. That explanation seems to me to gather strength every day, and to continually reveal itself as a more and more efficient solvent of the problems which present themselves to the student of natural history. At the same time, I am far from claiming for it the authority of a scientific creed, or even the degree of certainty which is possessed by some of the laws of astronomy. I only affirm that as a theory it has proved itself a potent and invaluable instrument of research. It is an immensely valuable induction; but it has not yet reached such a position of certitude as has been attained by the law of gravitation; and I have myself, in the field of botany, felt bound to protest against conclusions being drawn deductively from it without being subjected to the test of experimental verification. This attitude of mine, which I believe I share with most naturalists, must not, however, be mistaken for one of doubt. Of doubt as to the validity of Mr. Darwin's views I have none: I shall continue to have none till I come across facts which suggest doubt. But that is a different position from one of absolute certitude. It is therefore without any dissatisfaction that I observe that many competent persons have, while accepting Mr. Darwin's theory, set themselves to criticise various parts of it. But I must confess that I am disposed to share the opinion expressed by Mr. Huxley, that these criticisms really rest on a want of a thorough comprehension.

Mr. Romanes has put forward a view which deserves the attention due to the speculations of a man of singular subtlety and dialectic skill. He has startled us with the paradox that Mr. Darwin did not, after all, put forth, as I conceive it was his own impression he did, a theory of the origin of species, but only of adaptations. And inasmuch as Mr. Romanes is of opinion that specific differences are not adaptive, while those of genera are, it follows that Mr. Darwin only really accounted for the origin of the latter, while for an explanation of the former we must look to Mr. Romanes himself. For my part, however, I am altogether unable to accept the premises, and therefore fail to reach the conclusion. Specific differences, as we find them in plants, are for the most part indubitably adaptive, while the distinctive characters of genera and of higher groups are rarely so. Let anyone take the numerous species of some well-characterised English genus—for example, *Ranunculus*; he will find that one species is distinguished by having creeping stems, one by a tuberous root, one by floating leaves, another by drawn-out submerged ones, and so on. But each possesses those common characters which enables the botanist almost at a glance, notwithstanding the adaptive disguise, to refer them to the common genus *Ranunculus*. It seems to me quite easy to see, in fact, why specific characters should be usually adaptive, and generic not so. Species of any large genus must, from the nature of things, find themselves exposed to anything rather than uniform conditions. They must acquire, therefore, as the very condition of their existence, those adaptive characters which the necessities of their life demand. But this rarely affects those marks of affinity which still indicate their original common origin. No doubt these were themselves once adaptive, but they have long been overlaid by newer and more urgent modifications. Still, Nature is ever conservative, and these reminiscences of a bygone history persist; significant to the systematic botanist as telling an unmistakable family story, but far removed from the stress of a struggle in which they no longer are called upon to bear their part.

Another episode in the Darwinian theory is, however, likely to occupy our attention for some time to come. The biological world now looks to Prof. Weismann as occupying the most prominent position in the field of speculation. His theory of the continuity of the germ-plasm has been put before English readers with extreme lucidity by Prof. Moseley. That theory, I am free to confess, I do not find it easy to grasp clearly in all its concrete details. At any rate, my own studies do not furnish me with sufficient data for criticising them in any adequate way. It is, however, bound up with another theory—the non-inheritance of acquired characters—which is more open to general discussion. If with Weismann we accept this principle, it cannot be doubted that the burden thrown on natural selection is enormously increased. But I do not see that the theory of natural selection itself is in any way impaired in consequence.

The question, however, is, Are we to accept the principle? It appears to me that it is entirely a matter of evidence. It is proverbially difficult to prove a negative. In the analogous case of the inheritance of accidental mutilations, Mr. Darwin contents himself with observing that we should be "cautious in denying it." Still, I believe that, though a great deal of pains has been devoted to the matter, there is no case in which it has been satisfactorily proved that a character acquired

by an organism has been transmitted to its descendants; and there is, of course, an enormous bulk of evidence the other way.

The consideration of this point has given rise to what has been called the new Lamarckism. Now, Lamarck accounted for the evolution of organic Nature by two principles—the tendency to progressive advancement and the force of external circumstances. The first of these principles appears to me, like Nägeli's internal modifying force, to be simply substituting a name for a thing. Lamarck, like many other people before him, thought that the higher organisms were derived from others lower in the scale, and he explained this by saying that they had a tendency to be so derived. This appears to me much as if we explained the movement of a train from London to Bath by attributing it to a tendency to locomotion. Mr. Darwin lifted the whole matter out of the field of mere transcendental speculation by the theory of natural selection, a perfectly intelligible mechanism by which the result might be brought about. Science will always prefer a material *modus operandi* to anything so vague as the action of a tendency.

Lamarck's second principle deserves much more serious consideration. To be perfectly fair, we must strip it of the crude illustrations with which he hampered it. To suggest that a bird became web-footed by persistently stretching the skin between its toes, or that the neck of a giraffe was elongated in the perpetual attempt to reach the foliage of trees, seems almost repugnant to common sense. But the idea that changes in climate and food—i.e., in the conditions of nutrition generally—may have some slow but direct influence on the organism, seems, on a superficial view, so plausible that the mind is very prone to accept it. Mr. Darwin has himself frankly admitted that he thought he had not attached sufficient weight to the direct action of the environment. Yet it is extremely difficult to obtain satisfactory evidence of effects produced in this way. Hoffmann experimented with much pains on plants, and the results were negative. And Mr. Darwin confessed that Hoffmann's paper had "staggered" him.

Organic evolution still, therefore, seems to me to be explained in the simplest way as the result of variation controlled by natural selection. Now, both these factors are perfectly intelligible things. Variation is a mere matter of everyday observation, and the struggle for existence, which is the cause of which natural selection is the effect, is equally so. If we state in a parallel form the Lamarckian theory, it amounts to a tendency controlled by external forces. It appears to me that there is no satisfactory basis of fact for either factor. The practical superiority of the Darwinian over the Lamarckian theory is, as a working hypothesis, immeasurable.

The new Lamarckian school, if I understand their views correctly, seek to re-introduce Lamarck's "tendency." The fact has been admitted by Mr. Darwin himself that variation is not illimitable. No one, in fact, has ever contended that any type can be reached from any point. For example, as Weismann puts it, "Under the most favourable circumstances a bird can never become transformed into a mammal." It is deduced from this that variation takes places in a fixed direction only, and this is assumed to be due to an innate law of development, or, as Weismann has termed it, a "phyletic vital force." But the introduction of any such directive agency is superfluous, because the limitation of variability is a necessary consequence of the physical constitution of the varying organism.

It is supposed however, by many people that a necessary part of Mr. Darwin's theory is the explanation of the phenomenon of variation itself. But really this is not more reasonable than to demand that it should explain gravitation or the source of solar energy. The investigation of any of these phenomena is a matter of first-rate importance. But the cause of variation is perfectly independent of the results that flow from it when subordinated to natural selection.

VARIATION IN PLANTS.

Though it is difficult to establish the fact that external causes promote variation directly, it is worth considering whether they may not do so indirectly. Weismann, like Lamarck before him, has pointed out, as others have also done, the remarkable persistence of the plants and animals of Egypt; and the evidence of this is now even stronger. We at Kew owe to the kindness of Dr. Schweinfurth a collection of specimens of plants from Egyptian tombs, which are said to be as much as 4000 years old. They are still perfectly identifiable, and, as one of my predecessors in this chair has pointed out, they differ in no respect from their living representatives in Egypt at this day. The explanation which Lamarck gave of this fact "may well," says Sir Charles Lyell, "lay claim to our admiration." He attributed it, in effect, to the persistence of the physical geography, temperature, and other natural conditions. The explanation seems to me adequate. The plants and animals, we

may fairly assume, were 4000 years ago as accurately adjusted to the conditions in which they then existed as the fact of their persistence in the country shows that they must be now. Any deviation from the type that existed then would either therefore be disadvantageous or indifferent. In the former case it would be speedily eliminated, in the latter it would be swamped by cross-breeding. But we know that if seeds of these plants were introduced into our gardens we should soon detect varieties amongst their progeny. Long observation upon plants under cultivation has always disposed me to think that a change of external conditions actually stimulated variation, and so gave natural selection wider play and a better chance of re-establishing the adaptation of the organism to them. Weismann explains the remarkable fact that organisms may for thousands of years reproduce themselves unchanged by the principle of the persistence of the germ-plasm. Yet it seems hard to believe that the germ-plasm, while enshrined in the individual whose race it is to perpetuate, and nourished at its expense, can be wholly indifferent to all its fortunes. It may be so, but in that case it would be very unlike other living elements of organised beings.

I am bound, however, to confess that I am not wholly satisfied with the data for the discussion of this question which practical horticulture supplies. That the contents of our gardens do exhibit the results of variation in a most astonishing degree no one will dispute. But for scientific purposes any exact account of the treatment under which these variations have occurred is unfortunately usually wanting. A great deal of the most striking variation is undoubtedly due to wide crossing, and these cases must, of course, be eliminated when the object is to test the independent variation of the germ-plasm. Hoffmann, whose experiments I have already referred to, doubts whether plants do as a matter of fact vary more under cultivation than in their native home and under natural conditions. It would be very interesting if this could be tested by the concerted efforts of two cultivators, say, for example, in Egypt and in England. Let some annual plant be selected, native of the former country, and let its seed be transmitted to the latter. Then let each cultivator select any variations that arise in regard to some given character; set to work, in fact, exactly as any gardener would who wanted to "improve" the plant, but on a preconcerted plan. A comparison of the success which each obtained would be a measure of the effect of the change of the environment on variability. If it proved that, as Hoffmann supposed, the change of conditions did not affect what we may call the rate of variation, then, as Mr. Darwin remarks in writing to Prof. Semper, "the astonishing variations of almost all cultivated plants must be due to selection and breeding from the varying individuals. 'This idea,' he continues, 'crossed my mind many years ago, but I was afraid to publish it, as I thought that people would say, 'How he does exaggerate the importance of selection.''" From an independent consideration of the subject I also find my mind somewhat shaken about it. Yet I feel disposed to say with Mr. Darwin, "I still must believe that changed conditions give the impulse to variability, but that they act in most cases in a very indirect manner."

(To be continued.)

HARDY FRUIT GARDEN.

TAKING STOCK.—Now is the best time to take stock of all the fruit trees and bushes growing in various positions in order to determine which are worth keeping and which are not. In some instances the varieties do not merit the space given up to them, in others the trees are become unprofitable, and might well be replaced by young ones, while there are numerous cases where there is much valuable wall space not sufficiently utilised for fruit culture. It is not always wise to uproot large trees, of inferior varieties of Apples and Pears especially, the better plan being to re-graft these with others that are worthy of culture. Nor should any unhealthy or unfruitful trees of good varieties be too hastily destroyed, as it is quite possible to restore such to good health and free bearing order long before young trees could be grown into a profitable size. As a rule Apples and Pears remain in good health much longer than either Cherries, Plums, Peaches, and Apricots, and although these may be preserved in a profitable state for many years if liberally treated at the roots, it is yet advisable to have a few younger trees coming on to take the place of those no longer worthy of preservation. Especially is this necessary in the case of Peaches, Nectarines, and Apricots, any of these being liable to die off rapidly, and that, too,

in spite of various remedial measures resorted to. Gooseberries and Currants are also liable to lose large limbs, and young bushes ought to be in readiness to take their place. Raspberries, although not much addicted to dying off suddenly, will not go on doing well in one position for many years, and there are numerous gardens where inferior varieties are still tolerated. All the walls and fruit quarters should, therefore, be looked over and a final decision arrived at.

PREPARING FOR PLANTING.—Advantage should be taken of a fine dry time to prepare the sites for fresh trees, whether these be against walls or in the open. Not only can this be well done at this early date, but an early preparation allows better time for the deeply moved ground to settle before the time for moving the trees arrives. Not unfrequently the trees are prepared only a short time before the trees are planted, and unless allowance is made for the sure settlement of the soil the "collars" are bound to sink below the ordinary level of the garden or border, and this leads to excessively deep root action and a marked deterioration in the health of the trees. When the sites are prepared early, trees brought from the nurseries may, weather permitting, be planted directly they are received; this, seeing that in many instances they have already been long out of the soil, being another important consideration. Where whole quarters are to be newly planted the preparation of these should consist of bastard trenching or double digging, first, however, seeing that the drainage is in good working order, as fruit trees will not long thrive on badly drained land. It is not advisable to mix much rich manure with either the bottom or top spits. The trees will usually grow vigorously on fresh land, and manure added may cause gross unfruitful growth, while if deeply buried it inevitably encourages undesirable deep root action. Trees do exceptionally well in fresh loamy soils, or any in which plenty of turfy loam has been added, and this is far preferable to planting in heavily manured land. When manure is most needed is after the trees have exhausted much of the natural fertility of the soil and have arrived at a good free bearing condition. Given freely then and they will long remain in a profitable state. Trees planted in holes only a trifle wider than the spread of roots seldom grow away very satisfactorily, and where solitary trees are set out holes not less than 4 feet in diameter should be prepared for them.

REFILLING OLD SITES.—It is simply a waste of time and money to replant orchard ground that for many years has been occupied by fruit trees. Better by far break up a fresh piece of ground, as on this the trees, if properly attended to, rarely fail to do well, whereas any planted on soil already exhausted of all the food fruit trees most need, will seldom attain a serviceable size. The case is somewhat different in the enclosed kitchen and fruit gardens, where manure is used plentifully for the various crops of vegetables, in addition, perhaps, to liberal mulchings of manure given to the fruit trees. In very many instances, however, the wall borders in which trees have long been established are much impoverished below the surface and against the foot of the walls, and much of this poor soil ought to be changed for the best loamy soil procurable before young trees are put out in the place of worn-out old ones. The least that can be done is substitute fresh garden soil for that which has long supported fruit trees, and a liberal addition of ground bones is most beneficial in all cases. In low lying or badly drained positions each site for all choice fruit trees may well have a separate small pipe drain leading from it to the nearest main drain, one of which ought to be found under most of the principal walks near the walls. Such drains ought to be nearly or quite 3 feet deep, as, should they be placed much nearer the surface, the drainage may be too perfect, more moisture being sucked from the soil than is good for the trees to lose. A quantity of loose stones placed in the bottom of the holes will not long keep the roots from finding their way into cold clayey soil underneath, though they may assist in the drainage. On all heavy soils or other high planting should be practised, and this completed with good surface culture will serve to keep the roots nearer the surface.

THE FRUIT ROOM.—Every season the fruit room ought to have a thorough overhauling and a good cleansing given. The walls ought to be whitewashed and all the woodwork scrubbed down, the aim being to make the room as sweet as possible. Apples, and in a lesser degree Pears also, are very porous, and the flavour is easily tainted in a musty atmosphere or from contact with anything scented in any way. Nothing in the shape of hay or straw should be permitted in the fruit room, and the fruit ought either to be stored on the clean boards or on fresh "kitchen" paper.

FRUIT FORCING.

PEACHES AND NECTARINES.—*Planting Young Trees.*—The border must be efficiently drained, the base having an incline to the drain, which should be formed of 3 or 4 inch tiles having proper fall and outlet. It is not desirable to concrete the base unless it be wet or when the sub-soil is loose and likely to encourage the roots to enter it. Some ordinary gravel mixed with a third of lime formed into a mortar-like consistence and put in 3 or 4 inches thick, will form a suitable base. The surface of the concrete must incline to the drain, which should be laid in a hollow over the concrete. Use clean drainage—viz., a layer of brickbats not much less than half-brick size, another of smaller, and so on to the top layer of the size of ordinary broken road metal, and if covered with a layer of the siftings of old mortar rubbish about 3 inches thick, the drainage altogether being 12 inches thick, it will be a most satisfactory and substantial affair. The old mortar rubbish should be free from pieces of wood, using that remaining or not passing through a three-quarter-inch sieve. Good loam is the only suitable soil, the top 2 or 4 inches of a pasture with its turf. Add if inclined to be light a

fourth of clay marl finely divided, if very strong add a fourth of road scrapings. A small quantity (a twentieth) of crushed steamed bones may be added, and a similar proportion of wood ashes, chalk or old mortar rubbish freed of laths or other pieces of wood, to the extent of not less than a tenth. Ordinary loam will answer, but we prefer the turfy. In the case of ordinary garden soil, add the other ingredients according to the nature of the soil, and a fifth part of fresh stable manure free, as far as possible, of the straw; the materials to be well incorporated and in a fairly dry state, put together firmly. 24 inches depth is ample, and for ordinary sized trees 3 feet wide to begin with, or for tree two or three years trained to walls 4 feet 6 inches. Plant rather high, as the soil will settle and the surface dressings will raise the soil correspondingly. The earlier the trees are planted after the leaves show indications of falling the better, as fresh rootlets are produced at once. Supply water after planting, allow it to soak in, and when dry enough firm well and mulch with 2 or 3 inches thickness of short rather fresh manure. For early forcing confine the roots to inside, but in successional and late houses these roots may have to run of inside and outside borders.

For very early forcing Alexander Peach may be employed. There is no companion Nectarine, Advance is the earliest. For early houses—Hale's Early, Early Grosse Mignonne, A Bec, and Dr. Hogg, with Lord Napier Nectarine. Second early—Royal George, or its better form Stirling Castle, Grosse Mignonne, or Belle Bauce, and Alexandra (Noblesse), with Elruge, Violette Hâtive, and Rivers' Orange Nectarines. Succession houses.—The preceding are eligible with Bellegarde and Barrington Peaches, Dymond being excellent; and in addition to the Nectarines named above, White and Pineapple. Late houses—Barrington, Princess of Wales, Walburton Admirable, and Sea Eagle Peaches, with Pineapple and Victoria Nectarines.

Earliest House.—The trees are now leafless. If any pruning be necessary attend to it; but due regard having been paid to disbudding, preventing overcrowding, and removing the useless growths after the fruits were gathered very little will now be necessary. The trees should be dressed with an insecticide before tying them to the trellis. The borders may be pointed, the loose surface soil removed, and fresh loam added, with 20 per cent. of steamed bonemeal and a similar per-centage of wood ashes. The roof lights may remain off until November, when it will be necessary to replace them to ward off heavy rains and probably snow, air being freely admitted except during frost. Allow the outside borders of early houses to have the benefit of whatever rains may fall in October, afterwards protect with leaves and litter over it, with shutters or tarpaulin later on to throw off the wet.

Trees Started at the New Year.—The foliage is falling, but it comes off tardily, an indication that the wood is not so well solidified and matured as obtains with forced trees generally, yet the buds are plump and there is nothing to fear in respect of immaturity. Clear away the leaves as they fall, and when all are down lose no time in having the house thoroughly cleaned, the trees pruned and dressed and tied to the trellis, top-dressing the border as before advised unless the trees have been lifted or root-pruned this season, when it will not, of course, be necessary.

Succession Houses.—The foliage in these is quite green. The growths, however, are tolerably firm, and the buds appearing well in the axils of the leaves. The frosts have not affected the foliage (though 7° were registered on the 3rd inst.), and there is no indication of the foliage ripening. In the case of young trees it will be advisable, particularly where there is a tendency to late growth, to form a trench at a distance from the stem equal to about one-third the height of the trees, detaching all the roots, leaving the trench open for ten days or a fortnight, when it may be filled firmly. This will check the tendency to a late growth, and contribute to the maturity of the wood and buds. Care must be taken not to allow the soil to become dry in the part undisturbed, and detaching the roots will encourage the production of fresh rootlets, which will decidedly benefit the setting and stoning of the fruit in the ensuing season.

Late Houses.—The wood which has borne fruit may be cut out and thinned where too crowded. The house may be kept rather close by day when there is sun, throwing the house open at night, which will assist the wood to ripen, and concentrate the tree's energies on maturing the buds through the increased power of elaboration and assimilation by day, with rest at night. With a gentle warmth in the pipes in dull weather the ripening process will be still further enhanced, but it must be accompanied by a free circulation of air.

Late Unheated Houses.—In these structures a great change has been effected during last month, the fruit ripening very well, indeed it has been the best of the season. Bellegarde and Barrington have been excellent. We gathered the last of Barrington the same day (October 3rd) as the first fruit of Sea Eagle were gathered. The last is a grand fruit, pale straw colour, with a pink cheek, the flesh dissolving, with a rich racy flavour. It also fruits freely, and is remarkably free from disease, possessing an excellent constitution. There is nothing like it in Peaches except Early Rivers, which is one of the richest flavoured of the very early Peaches, and both were raised from the Early Silver Peach.

PLANT HOUSES.

Allamandas.—Withhold water from the earliest plants until they flag, for it is only by so doing that they can be brought to rest in moist heated structures. This can be done without allowing the wood to shrivel. Partially prune the plants, and when growth has been thoroughly brought to a standstill the plants will quickly go to rest in

a temperature of 55° provided the soil is kept rather dry at their roots until they have cast the whole of their foliage, when they may be kept perfectly dry. Supply weak stimulants to plants that are expected to flower for the next two or three months. To insure a continuous supply of flowers the plants must be kept growing, and to accomplish this the temperature should range from 60° to 65° at night.

Bougainvilleas.—Plants that have completed their growth should be induced to rest by placing them in a temperature of 55° where a drier atmosphere can be maintained. Gradually diminish the supply of water until their leaves have fallen, when they may be kept perfectly dry. Plants that have not yet completed their growth may have all small shoots removed, so that light and air can penetrate to ripen the main growths. This is essential if a good supply of flowers another year is to be obtained.

Clerodendrons.—Cuttings of *C. fragrans* that have recently been rooted may be placed into 4-inch pots, and if grown close to the glass and fully exposed to the sun they will produce serviceable heads of bloom. A few plants of *C. fallax* may be placed into the stove, and if they have been properly grown they will not be long before they are in full flower. Supply the whole of these plants with weak stimulants, but keep the remainder of the stock in a night temperature of 55° to 60°; they will move slowly forward in this temperature and form a capital succession.

Tydeas.—Place these in a light position as close to the glass as possible. This is important with late flowering varieties, or they will become tall. The early flowering varieties may be placed into the stove or an intermediate structure. Supply water freely to their roots, but be careful that it does not fall upon their foliage.

Gesneras.—Weak stimulants will benefit plants that have filled their pots with roots, and be careful that they do not suffer by an insufficient supply of water at their roots. They should occupy a shelf if possible where a moderate amount of humidity is maintained in the atmosphere. Water must not be allowed to settle upon their foliage, or it will soon present a rusty appearance. To do these well they must not be kept in a lower temperature than 60° to 65° at night until they are in full bloom.

Caladiums.—Be careful not to dry them suddenly or their tubers will perish. Keep them in the stove until the whole of their foliage has died, when they may be kept perfectly dry. Once they reach this stage they will be safe in a temperature of 50°, provided the soil is kept perfectly dry. *C. argyrites* should still be encouraged to grow, for its beautiful leaves are most ornamental when associated with cut flowers. We have succeeded best with this variety when no attempt has been made to dry it off.

Glorinias and Achimenes.—The earliest of these have gone to rest, and may be removed as opportunities offer from the old soil in which they were grown to be stored in pans or boxes until they are wanted again. They will be safe in any cool place from which frost is excluded, provided the sand or soil amongst which they are laid is kept perfectly dry. Do not prematurely dry off later plants, but water them judiciously until their foliage and stems show signs of decay, when water may be gradually withheld.

Sphærogynæ latifolia.—This and *Cyanophyllum magnificum* when well grown are conspicuous plants in the stove. Now that it has been necessary to diminish the supply of moisture in this structure, a sharp look out must be kept for thrips, which if allowed to become established upon the foliage of these will soon ruin them. Tobacco water applied with a sponge is the best means of destroying this pest if it appears.

THE BEE-KEEPER.

NOTES ON BEES.

BAD SEASONS.

"It may be safely asserted that there is scarcely a bee-keeper to be found who can recall such a disastrous honey season as the one now drawing to a close," was stated by a contemporary recently, but this is very inaccurate. Well managed bees, even in this disastrous year, either have or will give a surplus, and similarly managed stocks will not require any feeding. But it is very different with the unsuitable hives recommended by some writers and authorities, though surplus honey might have been obtained had proper hives and management been employed. I cannot recall every bad season that has occurred in my life, but I remember perfectly between 1835 and 1840 that the bees had to be fed during the whole summer. So great was the mortality amongst bees at that time that many bee-keepers lost all of them. Drip honey sold wholesale as high as 20s. for 5 lbs., and £10 was offered for one hive. I think it was in 1837-1838 that the Clyde was frozen as far down as Dumbarton Castle, and I remember well

being on board the "Old Vale of Leven" (the only steamer able that day to break the ice). After that April brought severe thunderstorms, as it did this year, and the summer was a cloudy one throughout. Skipping a few years, between 1845 and 1850, the seasons were as unfavourable. Then about 1852 we experienced one of the worst seasons on record. We had to feed our bees until they were taken to the Heather, and when there, for at least a month they did not get an opportunity to so much as air themselves. 1860, 1861, and 1862 were three bad years in succession, and in many places bees did not gather 5 lbs. the whole time. Other bad years were passed until 1877, when bees were dying of want at the end of July. I could name other seasons that have been worse for bees than the present one, but the above will suffice to show the accuracy of my statement. In one of these seasons, about 1860, honeycomb was sold in London at 7s. 6d. per pound.

CARNIOLIAN QUEENS.

In the same journal "Amateur Expert" makes some statements regarding striped v. plain Carniolian bees. Had he been a professional expert instead of amateur he would have done a good service to bee-keepers, and particularly to those people who make up their minds to die when a bee stings. He does not blame Mr. Benton directly for introducing banded Carniolians, but his article certainly conveys that meaning. I have had considerable experience with Carniolians, perhaps more so than any other person in the United Kingdom, and I have also had considerable experience, through correspondence with Mr. Benton, and know well the ill usage he has received at the hands of some English dealers. It is against the latter "Amateur Expert" should have directed his sarcasm. It is they alone who are responsible for importing impure Carniolians into this country. I have proof of it, and the worst of it is that they labelled the queen's cage as Frank Benton's first grade queens, while in fact they never had a queen from him. These are facts, and so are the following. Mr. Frank Benton, at great expense, and great risk to his own and family's health, went from America with a determination to hunt up new varieties of bees and present these to the public in a pure state. He has done this, but, like all true benefactors, is maligned, by people, too, who should have acted differently. Only from the English dealers have I received striped or crossed Carniolians, but from Benton not one but the pure, possessing their true amiability, he having done everything in his power to guard against impure blood.

But what about the stripes? "Amateur Expert" gives no information further than any amateur can do. It therefore does not appear as known to him that there are two sorts of stripes, the one indicating crossed bees, the other hereditary to the race, consisting of two spots at the sides or one ring of russet extending to the sides on the anterior part of the belly; this russet or russety brown does not extend beyond the hairs in the true type, but in the crosses it is well defined on the shell or skin of the bee, and these bees are generally of a vicious nature. I have had many queens from Benton both direct and from Messrs. Neighbour through him. These have not only been free from brown markings, but possess the true silvery appearance which characterises that race. Those that cannot be distinguished from black bees are not Carniolians.

THE COMBINATION OR LONG-IDEA HIVE.

I have read with interest the remarks upon the above hive by "A Hallamshire Bee-keeper," and was well pleased to see that he has had the pluck to tell your readers how old a hive it is. Long ago I kept bees in hives of that nature, and the late Mr. T. W. Woodbury not only kept bees in that kind of hive, but pointed out its defects, which were numerous, and these defects, as well as to the imperfect make of the hive in other respects, caused the death of the bees, and not as "A Hallamshire Bee-keeper" suggests, over-manipulation. I quite agree with much that "A Hallamshire Bee-keeper" states. Some points I may take up again, but at present I may state that there are other moves to be made with

bees than to the Heather. Some bee-keepers have to move their bees in April to the Willows and fruit blossoms, then to the Clover, and again to and from the Heather, and were there no hives but the combination type there would be few bee-keepers. Not only is the storifying or tiering hive the best for moving about, but it is the hive for profit as well.

By again following up the Simmins plan of requeening a hive I had a queen killed, the only one I have lost for a long time. Bee keepers should take the hint.

DAHLIA FLOWERS AND BEES.

I have never observed that these or any other flowers were injurious to bees. Our Mignonette this year has yielded much honey, and I have frequently observed bees in a sleepy state on it, but I attributed this to atmospheric influence and not to the flowers or honey, as the sleepy bees are always a very small per-centage of those that carry much honey and pollen from that or any other flower.—A LANARKSHIRE BEE-KEEPER.

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (W. Langley).—Thompson's "Gardeners' Assistant" will possibly answer your purpose. It is a large volume, and the price necessarily not low. It can be obtained through a bookseller.

Tomatoes (A. W. G.).—Write to Mr. James Webber, Central Avenue, Covent Garden, W.C.

National Rose Society's Catalogue (N. B.).—Write to the Rev. H. H. D'Ombrian, Westwell Vicarage, Ashford, Kent.

Echites (W. S. S.).—Some of the Echites succeed best in a stove, and some require a greenhouse temperature, but it is probable your plant is not a member of this genus, as the name is new to us.

Quick Hedge Shoots Dying (Heathfield).—You will find in another column some notes on the abundance of insect pests this season, especially referring to their effects on hedges. Perhaps also the soil is insufficiently drained or otherwise in an unsuitable condition.

Pride of Lincolnshire Pea (H. Marriott).—The specimen of haulm and pods testify to the productiveness of the variety, one stem containing eleven pairs of pods and three singles. We observed the dish that was sent to a recent meeting of the Royal Horticultural Society, and think a request was entered that the variety be sent to Chiswick for trial. The pods were very fine.

Tomatoes (Single-handed).—Perhaps your best course would be to send a specimen of the fruit to the firm from whom you had the seed, asking if the variety is true. The trials to which you refer were very carefully conducted, and you may rely upon their accuracy. With the other variety mentioned we have had no experience. We are gratified to learn that you have found the Journal useful, and we reciprocate all your good wishes.

Concrete for Vine Border (J. P.).—The most suitable material is gravel, which does not contain much, if any, loam or clay, but is of a non-binding nature. It may be passed through a sieve with inch mesh, using that passing through the sieve, and if very sandy it should be freed of it by a quarter-inch sieve, rejecting the sand. To the gravel add one part of freshly slaked lime to two of gravel, and form it into a mortar-like consistence by adding water and mixing. Lay it 4 inches thick, and evenly smoothing with the back of a spade. It may be laid on the subsoil, it being given the proper incline to the drain, which should be

laid on the concrete, the bottom falling to it from all points. The drain should have proper fall and outlet.

Trees and Shrubs for Clay Soil (C. L. J.).—Of the kinds you name *Ribes speciosum* is not likely to succeed unless given the protection of a wall. Lilac, single pink May, and Syringa, will no doubt do well, and the Lime may do so if there is no water lodging in the ground. Laurel and Austrian Pine will succeed, the latter bearing exposure well; indeed it is the best shelter tree extant. Butcher's Broom and Gum Cistus would suffer from frost. *Lonicera flexuosa* would do on the west aspect of the house, also *Bignoniaradicans sanguinea*, *Clematis Jackmanni*, *C. Henryi*, *Aristolochia Sipho*, and *Glycine sinensis*. *Jasminum nudiflorum*, *Cratægus pyracantha Lelandi*, and white Jasmine (*Jasminum officinale grandiflorum majus*) on the east. Two Roses for front of house may be *Gloire de Dijon* and *Rêve d'Or*, or *Celine Forestier*.

Hyacinths and Tulips in Pots (W. S. S.).—About six weeks are required for the pots to remain plunged in ashes after the bulbs are potted. In the absence of ashes sand may be employed, and if of a sharp gritty nature is quite as good. We invert a small pot over the bulb of the Hyacinth, and cover with about 6 inches of cocoa-nut fibre refuse. As both the Hyacinths and Tulips will have grown somewhat when they are removed from the plunging material, care must be taken not to expose them suddenly to strong light or powerful sun, but they must be gradually inured to it, so as to prevent the foliage being damaged. Placed in a light airy position in a greenhouse, they will flower in March and April. The Tulips we presume are of the usual early varieties. A suitable compost for potting the bulbs is turfy loam of medium texture broken up moderately fine, to which add a fifth of well decayed manure or a fourth of leaf soil and a sixth of sharp sand. A quart of soot may be added to every bushel of compost, and the whole thoroughly incorporated.

Ground Infested with Wireworm (H. C.).—The wireworms certainly change into a winged insect—viz., beetles, well-known under the names of click beetle, snap beetle, spring beetle, or skipjack. There are many species of click beetles. The most hurtful species, according to the observations of entomologists, are *Athous hemorrhoidalis*, *Agriotes lineatus*, *A. obscurus*, and *A. sputator*. Their depredations are in some instances known to continue over five years—i.e., when they are in the larval condition. They are most abundant on unbroken ground, in which they multiply and spread to adjacent ground. Soil that has lain fallow or has been in grass for some years and is broken up, is often so infested that the crops grown in it are apt to suffer severely from wireworm. Perhaps the most effectual remedy is to starve out the larvæ, merely turning over the ground frequently, alike to destroy weeds and expose the wireworms to the eyes of birds, particularly starlings. If this be objectionable, dress the ground with fresh gas lime at the rate of half a bushel per rod, disposing it evenly on the surface, and point in lightly with a fork; in fact the ground should be merely pricked over. This may be done now. In the course of a month or six weeks in favourable weather fork over the ground a spit deep. Let it lie until February, and then trench it as deeply as the good soil allows. It may be manured afterwards, pointing it in, and planted in due season with Gladioli. Pieces of Carrot or Potato may be used as traps after the Gladioli are put in. These should be turned a little beneath the surface, and removed daily, examined, and the wireworms on them collected and destroyed.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. We have several packages of fruit in which there is no indication of the name of the sender, and consequently it is impossible for us to notice them. (*Jno. Weaver*).—Loddington. (*Edmund Essing*).—1, Suffolk Thorn; 2, Comte de Lamy; 3, Fondante d'Automne; 4, Beurre Superfin; 5, Vicar of Winkfield; 6, Devonshire Queen (A.).—1, Beurre Rance; 2, Bergamotte Esperen; 3, Beurre Diel; 4, Beurre Langelier. (*Fullbrooks*).—The names of 1 and 4 were loose. The Pear is Bergamotte Esperen; the Apple not known; 2, Hawthornden; 3, Summer Strawberry; 5, Chaumontel; 6, Susette de Bavay. (*J. Mogridge*).—1, Beurre d'Amaulis; 2, Pearson's Plate; 3, Hawthornden; 4, Beauty of Kent; 5, Cellini; 6, Braddick's Nonpareil. (*G. L. Court*).—Maréchal de Cour, will succeed as a standard, but better as a bush. (*F. Alexander*).—1, Dumelow's Seedling; 2, Keswick Codlin; 15, Red Astrachan; 10, Lord Suffield; 18, Gravenstein; 14, Warwickshire Pippin.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*G. H.*).—We do not undertake to name varieties of *Pelargoniums*; 3 is *Abutilon Queen of the Yellows*; 4, *Nerine Fothergilli*; 5, *Abutilon vexillarium*. (*R. O. S.*).—1, *Asplenium cicutarium*; 2, *Adiantum scutum*; 3, *Adiantum farleyense*; 4, *Pteris internata*. (*W. P.*).—1, *Nerine coruscans*; 2, *Nerine Fothergilli major*; 3, *Lælia Perrini*.

OUR FUTURE.

AT Michaelmas we begin another farming year, and our plans for the ensuing twelve months have to be considered and arranged. In doing this lessons of the past are not forgotten, and possibilities of improvement in the future also have attention. Long experience has shown that it is unwise to take results of a season or two as our guide to plans for the future, but rather to take an average of seasons and results as a basis for our calculations. If, for example, we were to take the last two seasons, we have one of drought, and another of extreme changes, but chiefly remarkable for its low temperature and wet weather. The summers of 1886-7 undoubtedly afford proof of the uncertainty of our climate, and go to prove that however carefully a farmer's plans may be laid, however good his practice may be, his aims and ends may be defeated by untimely weather. Well, such difficulties are taken for granted by all sensible men, and they continue to plod on, doing their utmost for the land and the crops they put in it.

In doing this, the plodding is not confined to a slavish, blind

following of the practice of their forefathers, but they aspire to positive improvement, for both science and practice have taught them that the fertility of the soil can be increased. Do our readers require proofs? Well, we can give them abundant evidence of the truth of our postulate. Take, for example, the evidence of two of our tenant farmers at our last market. One of them, a worthy man enough, told us he had acted upon our advice to rear plenty of pigs, and he had now upwards of a hundred, but he had threshed his Wheat in a soft damp condition, and had sold it for 24s. a quarter; worse still, the crop would not average 4 quarters an acre. The other tenant came to us with a complacent smile, and he had quite a different story to tell. "I had to thresh some Wheat for the straw," said he, "and I found the yield was fully equal to 7½ quarters, or 60 bushels an acre, and I had no difficulty in getting 38s. a quarter, for the sample was a good one." We were not at all surprised at the wide difference in the results of these two men, for the successful man is a high, or shall we say a sound farmer, keeping plenty of sheep, and taking especial care to attend closely to every important point of good husbandry, while the other has to struggle with the difficulties which ever attend a farmer with insufficient capital for the perfect cultivation of his holding.

In this statement we know we only repeat an oft-told tale, but its truth and force will cause it to be told again many a time and oft, and we must insist now that it has been proved beyond a doubt that the fertility of soils can be increased; that consequently more and better crops can be grown per acre; and that, given reasonable reductions of rents, security for capital, reduced railway rates, co-operation in buying and selling farm produce, and better education in agriculture and its practice generally, there can be no reason for taking anything but a hopeful view of our future as farmers. But to insure this there must be no clinging to old customs, no faith in the mere assertion that the muck cart is the backbone of farming, but an intelligent teachable acceptance of the light shed upon modern practice by scientific research and actual results. Well does a contemporary observe that the old farmer uses the proverb that "muck is the mother of riches." What, then, is muck? Animal excreta mixed with straw. So far science and ancient tradition agree. But here ancient tradition comes to an end, while science goes on to inquire what these articles consist of and whether they can be found elsewhere. It then ascertains that what in them is of advantage to the crop consists chiefly, if not exclusively, of three ingredients—nitrogen, potash, and phosphorus, which together form only about one-seventieth part of the total "muck." Whether this statement is true in practice is next tested by practice. Portions of land are taken of equal sizes and of similar soil; they are sown and cultivated in identical fashion, but to one is applied a full dressing of "muck," to another a dressing of chemical powders, clean and inodorous, containing the same quantities of the three ingredients as the muck has been found to contain. The experiment is continued for a space of forty successive years on one estate, it is tried on different soils in other districts, it is made to yield exact knowledge by most careful weighing of every application and of every crop.

The result is to establish irrefutably the fact that these three ingredients are really the sole constituents of muck which add fertility to the soil, and that if we give them in the form of dry powders or of solutions they are as active and as beneficial as if bestowed in the form of artificial manure. One difference is only found to exist. They are in their separate form much more immediately active, but also less permanent in their action. The consequence follows that it is not necessary to apply so much at once, but that the application must be repeated more frequently. In all other respects we have come to know for a certainty, not merely that we can replace the farmyard manure by the "artificial" manure, but that by using the one in addition to the other we can raise additional produce, that we can thus not merely maintain the fertility of the soil, but very largely increase it, and that by such

means we can make an almost barren soil equally productive with one which Nature made rich.

WORK ON THE HOME FARM.

Very much of the more vigorous Barley was beaten down by heavy rain, and there was consequently so much difficulty in reaping it that more ears of grain are left out upon the stubbles than usual. None of this fallen corn will be lost, for pigs are taken out on the stubbles daily, care being taken to let them have water at mid-day and when they leave the stubbles in the evening. The scarcity of old straw caused many Barley stacks to be exposed to rain before the thatching was done. If, when such "weathered" stacks are threshed, the corn from the top of the stack is at all damp or soft, it had much better be used for the pigs than sold at a very low price as grinding Barley, for if realised in the form of pork it will certainly prove profitable, which it as certainly could not if sold at 22s. or 24s. per quarter for grinding.

Very little corn-threshing has been done as yet. We had all the Rye threshed, both because we required seed for sowing, and the surplus could only be disposed of advantageously now to buyers for the same purpose. The value of Rye as a green crop for early spring food is not fully realised by all farmers. It comes into use before any other green crop, gives a brisk second growth, which is available either for sheep or may be left to produce grain. If it is not required after the first growth is eaten off by sheep in folds it may be ploughed in in good time for a crop of Barley, or the land may be turned to account for a root crop. Roots, by-the-by, are so abundant that we have ordered an inferior crop of white Turnips to be ploughed in for Wheat. The Turniptops are vigorous enough, and there is a plentiful admixture of wild Oats among them, so that the green crop should impart enough fertility to the land for Wheat.

Wheat-sowing will be retarded both by the late harvest and by the late growth of the second crop of Clover. The first crop of Clover was altogether inferior and poor; the second, owing to the wet summer, is very abundant, and the difficulty has been what to do with it. We were able to fold some of it off with sheep, but it grew so fast and so strongly that the sheep were beaten and it had to be mown and harvested.

ENSILAGE.

THE sample of ensilage sent is from a silo opened last October, made from a mixture of Lucerne, Rye Grass, and grass cut between trees and round hedges, &c., salted and well trodden. The silo is made from a portion of a large brick barn with stone floor, a 14-inch wall built across the barn with a doorway left when built, then bricked up so as to be taken down when the ensilage is ready for use. One-third was cut in chaff before filling, and two-thirds put in long, chaff at one end, long at the other; but this year it is all put in long. There is a large loft above the silo, and the grass is carted and put in the loft and thrown down through trap doors into the silo, well shaken, salted, and trodden down firm. When filled wooden shutters were placed on the top and about 4 inches of bran on the boards, which were then weighted with several tons of stones. As used one shutter can be taken off and a portion taken down; thus there is not much exposed to the air. Bran for covering I find better than soil, as it can be used for pigs or with the chaff, and there is no grit to mix with the food. This year, instead of weighting with stones, two pieces of wood the length of the silo are put on the shutters, with three cross-pieces and small screw-jacks so as to give it level pressure. Small jacks to lift about 7 or 8 tons, with a large piece of timber fixed to the bottom of the beams in a loft to keep the jacks from raising them out of their place. I find it a very useful and not very expensive silo.—C. OSMAN.

[The sample sent we have previously referred to as remarkably sweet and excellent in all respects.]

REMARKS.

30th.—Brilliant autumnal day.
1st.—Brilliant all day.
2nd.—Cloudy morning, wet afternoon, fair evening.
3rd.—White frost, foggy early, hazy most of the day.
4th.—Fine bright morning, showers in afternoon and evening.
5th.—Bright morning and fine afternoon except for a heavy shower at 4.30 P.M.
6th.—Generally bright and fine; sprinkle of rain about 3 P.M., but no measurable quantity.
A generally fine week, with N. and W. winds, and clear sky, the effect of which has been to permit great terrestrial radiation, which has produced exceptionally cold nights, the average minimum being only 34.3°, or 16.4° below the previous week, and about that due to the 1st of January.—G. J. SYMONS.

CHISWICK.

CHISWICK may fairly be described as the centre of interest in the horticultural world this week, numbers of persons finding their way to the historic garden, while a vastly greater number who cannot do so will scan the reports of the proceedings in the Press, and derive hints therefrom that will be of service on the important subject of fruits—their selection and management.

The Exhibition is of great merit and magnitude, the noble vinery being filled with selections of Apples, and a huge marquise occupied with Pears, upwards of 5000 dishes of fruits being staged, forming one of the finest and most instructive displays that have been seen there or elsewhere. The Conference of growers and persons interested in fruit production, and the papers read each day, will render the week memorable. For the convenience of visitors and officials refreshments are provided in the curvilinear vinery and seed room, and only a continuance of fine weather is requisite for making the event a great success. Further particulars will be found in another page.

The old story of Chiswick being "too far away" to attract visitors would have weight probably, if what are called "shows," but which are only sections of what the public nowadays expect to find in an exhibition, were held at fortnightly intervals; but it is not too distant from everywhere when something worthy of its name and traditions is provided to command national attention, and that is what the work of a Royal Society ought to do. The gathering of fruit and fruit growers comes as a revival of life and spirit, and ought to have a strengthening effect, and do something to compensate for the waning meetings in Westminster. The "Drill Hall" gatherings have evidently become tiresome to nearly all concerned, and the events of the present week prove once more, and the lesson should not be lost, that Chiswick is still the backbone of the Royal Horticultural Society. Let London be its head, as it must be for a time at least, and the seat of administration, Chiswick as long as it exists must be the practical exponent of its work. It should be the national seat of horticulture, as Kew is of botany, and both should have a share of Government support for national purposes. It is by the application of horticultural practices to agricultural routine, in a greater measure than has hitherto prevailed, that the resources of the soil will be best developed and the value of land maintained and increased.

As a seat of education for focussing and disseminating information on the economical raising of food products Chiswick stands alone. The elements of success exist there, and have not to be created, neither can they be removed. They can be neglected, allowed to remain quiescent, or vanish; or they can be expanded, and with this expansion knowledge of the greatest importance could and would be gained and distributed, not for the advantage of a corporate body or a craft, but for the whole community.

It is natural enough for opposition to be called forth when State aid is suggested for a particular trade or industry. But horticulture in the abstract is not a trade, and is a great deal more than an industry. It is the root of all trades, for it is the parent of agriculture, on the well-being of which trades depend, for it provides the necessities of their existence, and the greater the provision is, the greater is the general prosperity. Chiswick should be a great educational establishment, as Kew is, and as such have a reasonable share of support from the State. Grants are made for the

promotion of education in the arts and sciences, also for the improvement of dairy farming, and why should not they be made in furtherance of profitable land cultivation, which is a subject of not less practical importance than any to which support is accorded? Chiswick is the experimental ground of the only chartered Horticultural Society in the kingdom, and therein rests its priority and singularity of claim. It should be a recognised school of instruction, maintained by and for the nation, testing by experiment the value or otherwise of different crops, the information so acquired to be at the disposal of all. That is what Chiswick ought to be in the interests of the common weal, and when an agricultural department is established by the Government, the opportunity must not be overlooked for the embodiment of horticulture therewith, for other than field crops must have attention in the future if the demands of the population are to be met to the utmost possible extent, as they undoubtedly should be, from British fields and gardens. With adequate means, and these in comparison with expenditure in other ways would be trifling, the Royal Horticultural Society could do service to the nation greater and better than any arising from private adventures conducted, as all adventures are, and must be, for personal gain.

The work done in the Gardens this year has been as good as the means for producing it allowed. The trials of Strawberries, Cabbages, Onions, Peas, Potatoes, and flowers have resulted in the indication and certification of varieties of prominent excellence, after the most careful comparison and critical examination by independent and competent men. Hardy fruit culture has been conducted in its various forms, and with such a collection of varieties as cannot be found together elsewhere. The best examples of pruning can be compared with culture in which the knife plays a very small part, and the results show that in the commercial production of fruit, regardless of the shape of the trees, the knife too freely used may be a costly instrument. The influence of stocks and varieties is apparent, and the popular fallacy exploded of the profitableness of the Blenheim Pippin Apple for planting. So-called fruit-growing advisers have presented the claims of this variety in such extravagant language in the newspapers that many persons must have been misled, and a corrective is needed. It is afforded at Chiswick, for of all the chosen varieties grafted and planted for trial during the last fifteen years, the much-extolled Blenheim is the most unprofitable of all, and the land occupied by trees of it would have given an infinitely better return if it had been cropped with Potatoes and Cabbages.

Visitors to the Garden have seen, and others will see, that Grapes worthy of inspection and profitable as a crop can be grown without an expenditure on borders greater than is incurred in the preparation of ground for ordinary fruit trees. The long range of Gros Colman shows what ordinary soil will do with a little fresh trenched in with it, supplemented by a rich surface dressing of manure and a few good dredgings of "Thomson's." Chiswick is, indeed, instructive in many ways, and might be made a great deal more so if adequate means were afforded for its management.

Other features of the gardens that have commanded attention this year were Figs in pots, bearing most abundantly and exemplifying mastery in their culture, and Tomatoes planted out in a large span-roofed house. It is doubtful if a finer example of Tomato culture has been seen this year than in the house in question. An engraving on another page gives an idea of what the plants were like a few weeks ago. £70 worth of fruit have been sold from them now, and much remains to be gathered. This is a splendid success in a notoriously bad Tomato season. Of the varieties grown Perfection is the chief, yielding the finest fruits and perhaps the most remunerative crop. Horsford's Prelude has borne an extraordinary abundance of smallish fruits, in long rope-like clusters—the freest setter of all. Ham Green Favourite, apparently a selection from Hathaway's Excelsior, has grown strongly and produced fine fruits, while the variety last named is still bearing

well. Tennis Bull, medium sized, round, and smooth, has given satisfaction, and the yellow fruited Blenheim Orange has yielded a good crop of fine fruit. Scarlet fruits sell the best in London, the largest of these realising the highest price; but it is worthy of note that the sweeter yellow fruits, according to the experience of Mr. Pearson of Chilwell, command 2d. a pound more than the reds in Nottingham market. This Tomato house has proved remunerative.

The collection of Chrysanthemums grown in pots cannot be a striking success, and the cost incurred in their culture will take the gilt off the Tomato gingerbread. Any experts if they had been consulted would have told the authorities who advocated the culture of these plants that they were too late in their decision. The best plants were gone at the time, and numbers of the newer varieties sold out. The plants have been grown as well as it was possible to grow them under the circumstances, but these were such as to render success as it is measured in these days a sheer impossibility, as every "Chrysanthemum man" knew when he saw the plants on their arrival in late spring. It is not suggested the display will be a miserable failure or anything of that kind, but it cannot rank with the best, and it is nothing but right that the cause be recorded.

NOTES FROM A HERTS GARDEN.

ON October 3rd 7° of frost was registered, 9° on the 5th and 8th. Every tender plant is blackened. Almost the only flowers that remain are the Michaelmas Daisies—namely, *Aster ericoides*, flowers white with yellow centre, which, if small, are numerous and one of the most elegant of the genus; *A. novæ-angliæ*, rose with orange centres; *A. novæ-angliæ rubra*, bright magenta; and *A. novæ-belgiæ*, with bluish-purple flowers in large heads. *Anemone japonica* and its var. *alba* are in fair condition, also *Tritoma Uvaria* and *Galtonia candicans*, but they are in somewhat sheltered situations, and so also are the perennial Sunflowers. The annual Sunflowers are over, though they were extremely gaudy before the frosts. What a very useful flower the "New Miniature" Sunflower is for decoration and cutting purposes. Its small, elegant, bright golden yellow single blooms with a dark velvet centre, borne abundantly from July to frost, render it peculiarly valuable, and its stems are long enough for most purposes, its neat foliage adding to its attractiveness. I would mention *Doronicum plantaginifolium* as being a very elegant plant with yellow flowers, usually solitary and terminal, which attains to a height of 4 to 6 feet, flowering in spring and more or less right away to October. But to return to the Sunflowers; how they have grown this year! They seem to enjoy the gloom and drip. One of the most graceful, best, and useful decorative autumnal plants is *Helianthus orgyalis*, which attains to a height of 6 to 10 feet; stem rigid, somewhat sparsely clothed with narrow recurved leaves alternately set; flowers yellow, small and numerous. *H. decapetalus* has flowers 2 or 3 inches across, solitary or terminal on short twiggy branchlets. August to October, height 5 feet. *H. multiflorus major* is a large form like *H. decapetalus*, the flowers being more numerous and larger, and it not infrequently appears as a reversion in plants of the double perennial Sunflower (*H. multiflorus flore pleno*), indeed the plants of the latter have during the past two seasons produced both forms in the same individuals. The single form is the stronger grower, attaining to a height of 5 feet, the double having a height of 3 to 4 feet. *H. multiflorus maximus* is a magnified form both in plant and flower of "major," attaining a height of fully 8 feet; flowers large, golden yellow, single; one of the best autumn plants. *H. rigidus* has glistening golden yellow flowers about 4 inches across, with chocolate disc, good as long as it lasts, its season being August. Its flower heads, and sometimes the stems, dry up before expansion in a most unaccountable manner. *H. atropurpureus* has scattered heads with a purple disc and yellow rays. It has purple stems, attaining a height of 3 feet or more. The Sunflower will grow in almost any kind of soil, but prefers a good moisture-holding one, and well repays for mulching and watering in dry weather.

One of the other most striking plants of the year has been *Echinacea purpurea*, with reddish-purple heads and a raised dark centre, the peduncle long, producing a solitary terminal flower head. In a cut state it is very quaint, the ray florets drooping handsomely. It is a hardy perennial, requiring a deep rich loam, when it grows 3 to 4 feet high. In fine contrast with the *Echinacea* is *Rudbeckia Newmanni* or *speciosa*, the flower heads 3 to 4 inches across, the ray florets orange, which contrast well with the black purple disc. It

is fine as a plant, and the flower-heads are superb in vases, &c., its long stalks, 6 to 9 inches, rendering it particularly valuable. *R. maxima* (or *speciosa* of some) has the ray florets drooping as in *Echinacea*; disc columnar, of a dull brown, flowers solitary. It attains to double the height of *R. speciosa* or *Newmanni*, and is a really handsome plant. *Arnica montana*; flower head yellow, 2 inches across, arranged in a corymb, freely produced during July to September. It is a showy species, attaining to a height of 2 feet. *Senecio pulcher* produced its large corymbose flower heads freely, ray florets purple (reddish), which are longer than the yellow disc. It grew to a height of 3 feet, and was fine when the frosts came, and had been for weeks. A strong soil evidently suits this plant.

Lilies have done badly. *Lilium longiflorum Harrisii* is the only one worth mentioning, but *Crinum longiflorum* seemed to revel in the wet, and flowered in July. The flowers are produced in an umbel of six to eight, funnel-shaped, the segments flushed with pink in the centre, and the peduncle is about 2 feet long. A bed of this superb plant has a graceful appearance; the flowers are delightfully scented, and it is quite hardy. The season seems not to have suited aquatics, yet Bullrushes have thrown more heads than usual, and the White Lilies (*Nymphaea alba*) had foliage and flowers of unusual luxuriance. The latter appears to enjoy a good deposit of tree leaves which are blown in annually. *N. odorata* has most unaccountably disappeared, but we have good plants of *N. odorata rosea* (Boston Water Lily), and *N. flava*, yet neither flowered. *Aponogeton distachyon* flowered in June and again in September. The Water Flag, like the *Nymphaeas*, likes a deposit of leaf soil. Its sword-like leaves are now grand, and its flowers are the showiest of the showy in their early summer season. There are few things that sooner get possession of space than *Villarsia nymphaeoides*; its leaves are pretty. Just when the frosts came the margin of the ornamental water was aglow with *Lobelia cardinalis*. We obtain a packet of seed, raise the seedlings in pans, prick off, and plant out one year, both in the water, on its edge, and out of the water, and get the next a flame of scarlet, dazzling beyond anything seen in the parterre.

Nelumbium speciosum out of doors has grown well and spread considerably, but there have not been any flowers. We hope for better luck next year, also with *N. luteum*, which, however, does not grow so freely as *N. speciosum*, yet it gains strength with age.—UTILITARIAN.

THE PROGRESS OF BOTANY.

VARIATION IN PLANTS.

(Continued from page 346.)

WHATEVER conclusions we arrive at on these points, everyone will agree that one result of the Darwinian theory has been to give a great impulse to the study of organisms, if I may say so, as "going concerns." Interesting as are the problems which the structure, the functions, the affinity, or the geographical distribution of a plant may afford, the living plant in itself is even more interesting still.

Every organ will bear interrogation to trace the meaning and origin of its form and the part it plays in the plant's economy. That there is here an immense field for investigation there can be no doubt. Mr. Darwin himself set us the example in a series of masterly investigations. But the field is well-nigh inexhaustible. The extraordinary variety of form which plants exhibit has led to the notion that much of it may have arisen from indifferent variation. No doubt, as Mr. Darwin has pointed out, when one of a group of structures held together by some morphological or physiological nexus varies, the rest will vary correlatively. One variation then may, if advantageous, become adaptive, while the rest will be indifferent. But it appears to me that such a principle should be applied with the greatest caution; and from what I have myself heard fall from Mr. Darwin, I am led to believe that in the later years of his life he was disposed to think that every detail of plant structure had some adaptive significance, if only the clue could be found to it. As regards the forms of flowers an enormous body of information has been collected, but the vegetative organs have not yielded their secret to anything like the same extent. My own impression is that they will be found to be adaptive in innumerable ways which at present are not even suspected. At Kew we have probably a larger number of species assembled together than are to be found anywhere on the earth's surface. Here, then, is ample material for observation and comparison. But the adaptive significance will doubtless often be found by no means to lie on the surface. Who, for example, could possibly have guessed by inspection the purpose of the glandular bodies on the leaves of *Acacia sphærocephala*, and on the pulvinus of *Cecropia peltata*, which Belt in the one case, and Fritz Müller in the other, have shown to serve as food for ants? So far

from this explanation being far-fetched, Belt found that the former "tree is actually unable to exist without its guard," which it could not secure without some attraction in the shape of food. One fact which strongly impresses me with a belief in the adaptive significance of vegetative characters is the fact that they are constantly adopted in almost identical forms by plants of widely different affinity. If such forms were without significance one would expect them to be infinitely varied. If, however, they are really adaptive, it is intelligible that different plants should independently avail themselves of identical appliances and expedients.

Although this country is splendidly equipped with appliances for the study of systematic botany, our universities and colleges fall far behind a standard which would be considered even tolerable on the Continent in the means of studying morphological and physiological botany or of making researches in these subjects. There is not at the moment anywhere in London an adequate botanical laboratory, and though at most of the universities matters are not quite so bad, still I am not aware of any one where it is possible to do more than give the routine instruction, or to allow the students, when they have passed through this, to work for themselves. It is not easy to see why this should be, because on the animal side the accommodation and appliances for teaching comparative anatomy and physiology are always adequate and often palatial. Still less explicable to me is the tendency on the part of those who have charge of medical education to eliminate botanical study from the medical curriculum, since historically the animal histologists owe everything to botanists. In the seventeenth century, as I have already mentioned, Hooke first brought the microscope to the investigation of organic structure, and the tissue he examined was cork. Somewhat later, Grew, in his "Anatomy of Plants," gave the first germ of the cell-theory. During the eighteenth century the anatomists were not merely on a hopelessly wrong tack themselves, but they were bent on dragging botanists into it also. It was not till 1837, a little more than fifty years ago, that Henle saw that the structure of epithelium was practically the same as that of the parenchyma plantarum which Grew had described 150 years before. Two years later Schwann published his immortal theory, which comprised the ultimate facts of plant and animal anatomy under one view. But it was to a botanist, Von Mohl, that in 1846 the biological world owed the first clear description of protoplasm, and to another botanist, Cohn (1851), the identification of this with the sarcode of zoologists.

Now the historic order in discovery is not without its significance. The path which the first investigators found most accessible is doubtless that which beginners will also find easiest to tread. I do not myself believe that any better access can be obtained to the structure and functions of living tissues than by the study of plants. However, I am not without hopes that the serious study of botany in the laboratory will be in time better cared for. I do not hesitate to claim for it a position of the greatest importance in ordinary scientific education. All the essential phenomena of living organisms can be readily demonstrated upon plants. The necessary appliances are not so costly, and the work of the class-room is free from many difficulties with which the student of the animal side of biology has to contend.

Those, however, who have seriously devoted themselves to the pursuit of either morphological or physiological botany need not now be wholly at a loss. The splendid laboratory on Plymouth Sound, the erection of which we owe to the energy and enthusiasm of Prof. Ray Lankester, is open to botanists as well as zoologists, and affords every opportunity for the investigation of marine plants, in which little of late years has been done in this country. At Kew we owe to private munificence a commodious laboratory in which much excellent work has already been done. And this Association has made a small grant in aid of the establishment of a laboratory in the Royal Botanic Garden at Peradeniya, in Ceylon. It may be hoped that this will afford facilities for work of the same kind as has yielded Dr. Treub such a rich harvest of results in the Buitenzorg Botanic Garden in Java.

Physiological botany, as I have already pointed out, is a field in which this country in the past has accomplished great things. It has not, of late, however, obtained an amount of attention in any way proportionate to that devoted to animal physiology. In the interests of physiological science generally this is much to be deplored; and I believe that no one was more firmly convinced of this than Mr. Darwin. Only a short time before his death, in writing to Mr. Romanes on a book that he had recently been reading, he said that the author had made "a gigantic oversight in never considering plants: these would simplify the problem for him." This goes to the root of the matter. There is, in my judgment, no fundamental biological problem

which is not exhibited in a simpler form by plants than animals. It is possible, however, that the distaste which seems to exist amongst our biologists for physiological botany may be in due in some measure to the extremely physical point of view from which it has been customary to treat it on the Continent. It is owing in great measure to the method of Mr. Darwin's own admirable researches that in this country we have been led to a more excellent way. The work which has been lately done in England seems to me full of the highest promise. Mr. Francis Darwin and Mr. Gardiner have each in different directions shown the entirely new point of view which may be obtained by treating plant phenomena as the outcome of the functional activity of protoplasm. I have not the least doubt that by pursuing this path English research will not merely place vegetable physiology, which has hitherto been too much under the influence of Lamarckism, on a more rational basis, but that it will also sensibly react, as it has often done before, on animal physiology.

(To be continued.)

SURFACE RENEWAL OF VINE BORDERS.

So much has been written on this subject that to bring forward anything really new would, I think, be rather difficult, but as the time for lifting unsatisfactory Vines has now arrived, I venture to make a suggestion. Mr. Abbey a short time back pointed out the errors of planting Vines deeply, and advised lifting the roots to the surface. I have seen a few vieries the occupants of which have been so treated, and it has been two or three years before anything like a full crop of fruit could be taken. Is there a preferable way to lifting the Vines? I think there is in many instances—namely, by taking the surface to the roots instead of bringing the roots to the surface. Obviously this would only be beneficial when the drainage is correct and the border good. The roots of numbers of Vines are too far from the surface. Year after year manure has been placed on the border, to the injury instead of benefit to the roots, by keeping out the sun's warmth. If the soil be taken off well down to the roots, and a light dressing of good compost given, then covered well with some strawy manure for the winter to be taken off in spring, I think it would in many cases give more satisfaction and less anxiety than lifting the roots, especially in cases where gardeners are entering on new duties, and wish to make an improvement the first season without the risk of failure through careless lifting.—EXPERIMENTO.

THE CULTIVATION OF THE CUCUMBER.

The Cucumber is very popular in this country, and indeed in most countries on the Continent of Europe, in India, Africa, and America, where it is grown in great quantities and used in salads, pickles, and sometimes as a vegetable dish, but in this country it is principally grown as a salad.

There are several ways of cultivating the Cucumber, but the simplest of these is the method generally adopted by market gardeners in the open air by forming ridges or mounds, and the Cucumbers which grow are a small variety which is sold very readily to greengrocers and others from 1s. to 1s. 6d. per dozen during the summer months. The ridges are made and the plants cultivated in the following manner. After the ground has been selected it is marked out in 4-foot beds, and a trench dug 2 feet wide and 1 foot deep in the centre of it, which is filled with hot stable dung a little higher than the level of the surrounding ground, and the soil which is dug out is then spread over it when finished, forming a ridge. The seeds are then sown five or six together in a little clump on the top of the bed at the distance of 4 feet apart, and hand-glasses placed over each clump. When the plants are large enough to distinguish which are best, three of the most promising are left to cover the space between the clumps. Great care must be exercised in giving air and watering the plants as they grow, and when they fill the light three little stones can be placed under it to allow the plants to get out, which should be encouraged to cover the ground as quickly as possible. The after treatment consists in watering, stopping the points of the shoots, thinning and removing bad leaves. When the sun is scorchingly hot sometimes it is found necessary to shade the tender plants with Rhubarb leaves until they are thoroughly established, after which the same care is not needed, and the handlights may be removed altogether with safety. Cucumbers grown on the ridge system are more subject to the attacks of slugs than those in frames, therefore they should be carefully looked over every morning and the pests destroyed, or they would soon ruin the plants.

FRAME CULTURE.

Cucumbers are now mostly grown in frames by amateurs and in small gardens where there are no glass houses or pits; but at one time before glass was so cheap they were grown in frames by the most practical gardeners in the country. The great art in this method of culture is in making the hotbed, the materials for which may consist of stable litter, leaves, or spent tanner's bark. The bed may be made wholly of stable litter or of litter and leaves mixed together, or of barks and litter mixed together, according to convenience. The litter for this purpose should be thrown up in a heap to heat and turned over frequently to allow the rank gases to escape before the bed is made. If

leaves are mixed with the dung the bed will retain a steady heat much longer than if it was made of dung alone. In making the bed it should be 18 inches wider than the frame all round, and about a foot or 18 inches higher at the back than in the front. When the bed is made of dung and leaves, or of dung by itself, it should be well shaken up, the sides made square, and the surface beaten well with a fork as the work proceeds, but it should not be tramped until the last thing before the frame is placed on it. In making a bed with litter and spent tanner's bark the sides should be built with the rough dung and the centre filled with a layer of barks and dung, time about, and finished in the same way as the bed made of dung and leaves by tramping it all over before the frame is put on to keep it from sinking in one place more than in another. When the frame is put on the bed place a few good turves with the grass side down over the centre of it to keep down the strong heat, which, if too strong, might injure the roots of the young plants; after which form small hillocks in the centre of each light with a composition of loam and leaf mould in equal parts, and as soon as the heat of the soil is suitable, which may be ascertained by plunging a trial stick in it, the young plants may be placed out, two in each hillock, and supplied with tepid water, and the lights placed on the frame.

The after cultivation consists in stopping and training the growths of the plants, watering, shading, giving air, when the thermometer rises above 70°, and adding fresh soil to the bed as the plants grow, until the frame is filled. Some growers train the plants in the hillock, one to within 6 inches of the front, and the other to within 6 inches of the back of the frame before stopping them, while some cultivators stop the plants after they have made four or five leaves, which causes them to send out lateral shoots and come into fruiting a little sooner than those allowed to grow to within 6 inches of the sides before being stopped, but the plants are never so strong as those allowed to grow to near the sides of the frame. As the plants grow they should be stopped at one joint above the fruits, and all the male flowers and tendrils taken off as they appear, and one fruit only allowed to a joint, which should be placed in a glass tube for the purpose, if straight fruit is desired. When the frame is filled with stems and leaves some of the older ones may be thinned to allow a free circulation of air amongst them, and as the summer advances and the weather becomes warm large flower pots can be placed under each corner of the frame to allow the plants to grow outside.

Cucumbers grown in a hotbed made of dung do not require so much water as those in a bed heated by hot-water pipes, because the dung decays and becomes moist, and the roots penetrate deeply into the bed, which is not the case in beds heated by hot-water pipes. In the early stage of their growth air should be admitted carefully as soon as the sun comes out in the morning, but not before the glass has risen to 75°, and the frames closed early in the afternoon to husband heat, and the plants syringed. During very hot sunshine, when the plants are growing rapidly, they should be shaded for a few hours during the middle of the day, and in close town gardens like Cardiff Castle they would be all the better of a slight permanent shade made of whiting, lime, or buttermilk.

HOUSE CULTURE.

Enormous quantities of Cucumbers are now grown in the vicinity of all our large towns by market gardeners who make it a speciality. Span-roofed pits, 12 feet wide and 9 feet high, with a walk down the centre and beds on each side, with ventilation in the top, and heated by means of hot-water pipes, are specially constructed for growing them, so as to have fruit all the year round; but, as a matter of fact, it does not pay to grow Cucumbers during the winter months. I am credibly informed, however, that some of the large London market establishments produce no less than three or four millions of Cucumbers during the season, which are readily disposed of in Covent Garden Market at remunerative prices. The highest prices, however, are obtained in the spring and early summer months, when salmon is plentiful. There are two methods adopted in growing Cucumbers in pits, the express and the non-express systems. The express system consists in never giving air to the house at any time, and the non-express system in giving air when the temperature rises above 70°. I have not had any experience with the former, and will therefore confine my remarks to the other, or usual way of culture adopted in this district by gardeners.

To obtain Cucumbers in April and May the seed should be sown in the beginning of January in 48-sized pots and plunged in bottom heat. When the plants are large enough they are potted off into 3-inch pots and placed as near the glass as possible to encourage them to make a good sturdy growth, giving them plenty of heat and moisture. When they are 9 or 10 inches high they should be planted out in their permanent quarters at a distance of 5 feet apart. The soil should consist of half loam and half leaf mould, with a sprinkling of soot and wood ashes, all thoroughly incorporated. The pit or bed should be well drained, and the drainage covered with about 4 inches of good decayed manure, and filled to its proper height with the soil at once, and made firm by pressing it down all round with the feet or hands. After this strong neat stakes should be placed in the bed at the allotted distance and tied to the trellis. The plants should be planted close to the stakes, and as deep as the cotyledons, made firm all round, and trained to the stakes with a clean stem till they meet the trellis, when the lateral shoots are allowed to grow, which should be stopped at the first joint above the fruit, but the leading shoot should not be stopped until it grows to within a foot of the top of the trellis. After this the principal work consists in tying-in the shoots as they grow, stopping them, and removing old leaves, male flowers, and tendrils as soon as they appear. The plants

should be encouraged to make a free growth by giving them plenty of liquid manure when they require it, and the house should be closed up in the afternoon to husband sun heat, and the plants well syringed.

The most destructive insects to the Cucumber are green fly and red spider. The former can be destroyed by fumigating with tobacco or tobacco paper, and the latter by washing the affected leaves as soon as it is noticed, and copiously syringing the plants night and morning. The Cucumber is subject to mildew and to a disease peculiarly its own, which is called "the Cucumber disease." The former can be destroyed by applying flowers of sulphur to the affected parts, but there is no good remedy known yet for curing the latter, which is a fearful scourge when it enters a Cucumber plantation, either in the house, the hotbed, or on the outside ridges.

I have said nothing about the varieties which are best for each of these systems. For the house and hotbed I would recommend Cardiff Castle, and for ridge culture a small variety called Stockwood.—W. ARTHUR TRESEDER.—(Read at a meeting of the Cardiff Castle Gardeners' Improvement Society.)

TREBBIANO AND WHITE TOKAY GRAPES.

WE have received two letters during the past week in which information is sought relative to the characteristics of these Grapes and

FIG. 39.—TREBBIANO GRAPE.

the differences between them. We know of no other way in which the subject can be made so clear as by citations from Mr. Barron's work on Vine culture and the illustrations the author has obligingly placed at our disposal.

TREBBIANO.—An oval white vinous Grape. Season: late. Merits: second-rate in quality, but valuable for its handsome appearance and late-keeping properties.

Vine.—Growth remarkably strong and robust, the young shoots being very thick, almost gross, but ripening freely; they are generally coated with down around the buds, which are large and prominent; moderately fruitful. Leaves large, soft, and much covered on the under surface with thick down; deeply toothed, dying off pale yellow.

Fruit.—Bunches of the very largest size, with broad, strong shoulders, and thick stalks, compact and always well set. Berries, medium-sized,

roundish-ovate, on stout footstalks. Skin greenish yellow, changing to pale amber when well ripened, tough or thick. Flesh firm, yet juicy, sweet, and pleasant, but lacking richness, excepting when very highly ripened.

History, &c.—The origin or introduction of this well-known Grape is unknown to us. It is largely grown for late work. Some of the finest examples we remember to have seen were grown by the late Mr. Drewett when gardener to Mrs. Hope at The Denbies, Dorking, Surrey; hence it was by some termed the Denbies Trebbiano. Mr. Curror of Eskbank exhibited at Edinburgh in 1875 a bunch of this Grape weighing 26 lbs. 4 ozs., which is the largest bunch of Grapes on record.

Cultural Notes.—Being of strong growth this Grape requires considerable space to develop properly; and, although it fruits freely along with Black Hamburg, it well repays treatment similar to Muscats. Mr. Gilbert, of Burghley, who is one of the best cultivators of the Trebbiano we know, gives plenty of time and plenty of heat to ripen it thoroughly, when the berries keep sound into March and April, and are then very rich.

WHITE TOKAY.—An oval white vinous Grape. Season: late. Merits: a first-class white Grape, very worthy of cultivation.

Vine.—Growth remarkably strong and vigorous, with a fine free constitution, the young shoots very strong and always ripening well; very free-fruited. Leaves large, deeply toothed.

Fruit.—Bunches above medium size, regularly formed, on strong footstalks, having strong shoulders; compact; always freely set. Berries large, ovate. Skin thick, greenish white, showing the venation through, becoming pale amber when fully ripe. Flesh firm, yet tender and juicy, with a sweet, pleasant, or sometimes rich flavour.

History, &c.—An old Grape, at one time much more extensively grown than it is at present, and confused to some extent with the Muscat of Alexandria, which in the north used to be called Charlesworth Tokay.

Cultural Notes.—Will succeed in any house suitable for the Black Hamburg, but requires longer time to ripen thoroughly.

It will be observed that apart from the differences in the fruit the buds and under sides of the leaves of Trebbiano are downy, while those of the White Tokay are not. The work named in its reduced form should be in the hands of all growers of Grapes, and can be obtained from this office post free for 5s. 3d.

DISA RACEMOSA.

In a recent issue of this Journal we gave an illustration of this Disa, and in the "Botanical Magazine" for the present month a coloured figure of the same species is given, with the following particulars by Sir J. D. Hooker and Mr. H. Bolus.

I am indebted to Mr. Bolus, who is preparing at Kew a Monograph of the genus Disa (for publication in the Transactions of the South African Philosophical Society) for the characters and the following description of this beautiful plant. It is, as he informs me, a native of moist grassy places on the eastern side of Table Mountain, Cape Town, at elevations of 800 to 2500 feet, flowering in December and January, and it extends thence eastward to Grahamstown, where it has been found by Professor MacOwan, now Superintendent of the Cape Botanical Gardens. It belongs to a section of the genus established by Mr. Bolus under the name of "Vexillata," in which the dorsal sepal is erect, nearly flat or slightly saccate; the petals inarched and subexserted; the lip usually narrow; the rostellum high, erect, protruded or reflexed, its arms usually divaricate, and the column itself is produced behind into a petaloid appendage, which embraces the long narrow ascending or reflexed anther. This group contains four species.

D. racemosa was brought to the Royal Gardens from the Cape by Mr. Watson, foreman of the propagation department, who visited that colony in 1887, and it flowered in May of the present year.

DESCRIPTION.—Erect, glabrous, 15 to 30 inches high; stem nearly straight, slender, distantly clothed with close wrapping sheaths with shortly spreading points. Leaves four to six, radical, linear-lanceolate, acuminate, laxly spreading. Racemes distantly four to nine-flowered; flowers subsecund, deep rose-red; bracts broadly ovate, acute, erect, about as long as the ovary. Lateral sepals broadly elliptic, obtuse, mucronulate below the apex, spreading, about ten lines long, seven to eight lines wide; dorsal sepal ovate, concave, obtuse, bluntly and widely saccate behind just below the middle, about nine lines long and five in depth. Petals obliquely oblong, apex incurved, posterior margin crose, meeting and arching

over the anther, adnate to the column at the base. Lip linear, acute, five lines long. Column erect or ascending; rostellum with divaricate arms, bearing the glands at their apices, furnished posteriorly with a petaloid appendage reaching half way up, and closely embracing the anther; glands facing the front of the flower.

FIXED TEMPERATURES.

It gives me much pleasure to read the opinions of Messrs. Bardney and Young on this subject. I mentioned on page 261 that this gardening fad is not yet obsolete; I am afraid far from it. It is surprising to note the obstinate opinion some gardeners still maintain on this head, in spite of their neighbours growing their crops equally well, and in

FIG. 40.—WHITE TOKAY GRAPE.

some cases even better than they, by the rational treatment set forth by Mr. Bardney on page 343. That such treatment will give satisfactory results goes without the saying, for it can be seen clearly demonstrated every day. What unpleasantness is often caused between the chief and his assistants through these fixed temperatures! Mr. Bardney seems fully alive to the best "ways and means" of maintaining these fixed temperatures. Can young men be blamed for resorting to these illegitimate means when they know perfectly well the chief will be round perhaps in a few minutes? If the mercury does not rise to the number that is attached to the top of the thermometer, means are used to make it do so. On the other hand, if the temperature is too high up goes the lights till the house is near the "fixed" standard. I trust all those gardeners that insist on these conditions will think seriously whether they are gaining by such hard and fast rules. A house that is forcing bad far better stand 5° too high than open the lights in such a manner. Is the excess or the sudden chilling blast the more detrimental to plant

life? These and many others are questions that should come to all of us. That such gardeners and assistants are not myths I have ample proof. Can head gardeners wonder at their assistants deceiving them, when they insist on such unreasonable conditions? for everyone is well aware how difficult it is to keep these fixed temperatures when the temperature outside rises or falls rapidly, or when the wind is very rough. Where fixed temperatures are insisted upon I know it is very unpleasant for all concerned, for many places are deficient in heating apparatus, or the pipes are not laid properly; and then it is well nigh impossible to keep every house at any fixed degree.—JAMES B. RIDING.

ROYAL HORTICULTURAL SOCIETY.

NATIONAL APPLE AND PEAR CONFERENCE.

THE Exhibition of Apples and Pears in the Chiswick Gardens which opened on Tuesday last, the 16th inst., and closes to-morrow (Friday) evening, the 19th inst., is a very remarkable one, and though lacking the novelty that attached to the Apple Congress held in 1883, and the Pear Conference of 1885, it to a large extent combines the merits of both with some special characteristics of its own. There can be no doubt that from a purely practical point of view the present one is the best of the three, and when the official or select lists of varieties are issued they may be expected to possess more than ordinary value. It was a wise determination on the part of the Committee to restrict the number of varieties shown by each exhibitor, as it is only by such means that anything like useful selections for different districts could be obtained. That the exhibitors have fully entered into the spirit of the idea is amply proved by the care which, in the majority of cases, has been displayed in excluding worthless varieties and representing only the best. In a few cases perhaps it must be concluded that the exhibitors have bad trees, bad soil, a bad climate to contend with; but although there is a considerable difference in the size and quality of Apples and Pears staged from various districts, it is noticeable that the individual collections are more even, and consequently more satisfactory, than on the two previous occasions. At these meetings the struggle seemed to be who should show the largest number of varieties, and in consequence many of little merit were represented, and some that, except as curiosities, were absolutely worthless. However, both the former Conferences at Chiswick performed valuable service, and it is a subject of general remark that a most noteworthy illustration of this is afforded by the more accurate nomenclature displayed throughout the Exhibition.

Apples, of course, constitute the major portion of the Show, being in fact by far the most interesting and attractive feature. Pears are generally rather under the average size, and besides being wanting in the colour which renders the Apple display so varied and bright, they occupy a somewhat dark tent that certainly does not add to their effect. Over 5000 dishes are staged of Apples and Pears together, contributed by about 100 exhibitors, coming from all the chief fruit-growing districts from Devonshire to Scotland. The home counties are particularly well represented, Herts, Kent, Middlesex, and Sussex especially so, the collections of Apples from these counties constituting the best part of the Apple display. The large vinery or conservatory presents a beautiful appearance; not perhaps so bright as at the 1883 Congress, but there is a sufficient number of highly coloured Apples to render the effect very pleasing. The whole of this building is occupied with Apples, two tables extending the full length of the house, in addition to the side stages, being filled with exhibits. The great class for fifty varieties, in which there are sixteen exhibitors, fills the whole space of one of these tables, and would alone form a show of much importance and interest. The opposite table is mainly occupied with classes 2 and 3 for twenty-four varieties best adapted to the exhibitor's district, and the best twelve varieties of Apples respectively, the former class containing no less than twenty-nine entries, and the other nine. The side stages are filled with some of the smaller classes, such as those for six and twelve varieties of dessert and culinary Apples, Apples from cordons, bush, pyramid, and standard trees, those grown on special stocks, market varieties and new varieties.

To the Pears the large tent already noted is appropriated, a smaller one also being filled with these and a few Apples for which space could not be found in the conservatory. Ten classes are devoted to Pears, and the entries range from two in the market class to seventeen in that for twelve dessert varieties.

As regards quality the Apples are highly satisfactory, and they afforded a very agreeable surprise to many visitors who expected in such a season as the present one to find a considerable deficit both in size and quality. Many handsome fruits are shown, some probably having had the protection of glass, but there are abundant satisfactory specimens from trees in the open, and it must be said in justice to the nurserymen that the majority of these are exceptionally good for the season. On another occasion it might be advisable to provide a separate class for orchard house fruits, for at an exhibition of this character there is a danger that inexperienced persons might be disappointed when they failed to procure such magnificent fruits upon ordinary outdoor trees.

As already remarked the nomenclature is generally satisfactory throughout, but some of the exhibitors have taken rather more trouble than merely to furnish the names. For example, in the Dalkeith collection of Apples from Mr. Dunn a very neat card is employed which gives

useful information regarding the season of the variety, quality, style of tree, stock, &c. The fruit itself in this case suffered greatly in transit, but the idea of labelling is an excellent one for meetings of this character; indeed, if it were carried out at ordinary competitive shows their interest and usefulness would be materially increased. At the first Apple Congress forms of a similar character were supplied to the exhibitors, and much of the information thus secured was embodied in the admirable official reports subsequently issued. The Committee will no doubt be able on the present occasion to add considerably to the facts recorded both in the Apple and Pear reports, and any kind of elections based on the reduced lists of select varieties will possess much practical value. At the same time the individual selections will be of especial local interest as indicating the varieties that have proved most reliable in each particular district.

We cannot give details of the classes or varieties this week, but the following are some of the principal exhibitors, and we hope to refer again to the best collections for which commendations or some other suitable recognition will be awarded by the Committee. The leading amateur exhibitors are the Messrs. Rothschild, Gunnersbury Park, Acton (gardener, Mr. Roberts); A. H. Smee, Esq., The Grange, Wallington (gardener, Mr. Cummins); the Earl of Warwick, Warwick Castle (gardener, Mr. Christie); Mr. J. Rust, Eridge Castle Gardens, Tunbridge; Mr. J. Grex, Normanton Park Gardens, Stamford; Rt. Hon. Sir T. D. Ackland, Kellerton, Exeter (gardener, Mr. Garland); the Duke of Newcastle, Clumber, Worksop (gardener, Mr. Gleeson); W. E. Brymer, Esq., Ilslington House, Dorchester (gardener, Mr. Powell); H. M. Middleton, Esq., Bradford Peverill, Dorchester (gardener, Mr. Gallop); the Earl of Ducie, Tortworth, Gloucester (gardener, Mr. Shingles); H. A. Brassey, Esq., M.P., Preston Hall, Aylesford (gardener, Mr. Waterman); Lady Frances Fletcher, Kenward, Yalding (gardener, Mr. R. Smith); Sir R. Sutton, Bart., Benham Park, Newbury (gardener, Mr. J. Howe); Peter Thellussen, Esq., Brodsworth Hall, Doncaster (gardener, Mr. W. Chuck); J. R. Rolls, Esq., The Hendre, Monmouth (gardener, Mr. Coomber); W. Roupell, Esq., Harvey Lodge, Roupell Park; H. J. Atkinson, Esq., M.P., Gunnersbury House, Acton (gardener, Mr. Hudson); Mr. W. G. Pragnell, Sherborne Castle Gardens, Dorset; and Mr. Sidney Ford, Leonardslee Gardens, Horsham.

The principal trade exhibitors are Messrs. J. Veitch & Sons, Chelsea; G. Bunyard & Co., Maidstone; T. Rivers & Son, Sawbridgeworth; J. Cheal & Son, Crawley; Wm. Paul & Son, Waltham Cross; R. Veitch and Sons, Exeter; Dicksons, Chester; T. Bunyard, Ashford; H. Lane and Son, Berkhamsted; C. Turner, Slough; C. Lee & Son, Hammer-smith; Paul & Son, Cheshunt; J. Watkins, Pomona Farm, Hereford; C. G. Sclater, Exeter; Lucombe, Pince & Co., Exeter; W. H. Frettingham, Beeston, Notts; J. Jefferies & Son, Cirencester; Saltmarsh & Son, Chelmsford; Laing & Sons, Forest Hill; and Peed, Norwood.

On Tuesday the opening ceremony took place at three o'clock, in the conservatory, when Sir Trevor Lawrence, Bart., M.P., delivered an inaugural address to the exhibitors and about fifty visitors. He said that, as President of the Royal Horticultural Society, he had great pleasure in declaring the Exhibition open. He was not entitled to express any opinion upon the subject of fruit cultivation, but he knew that a great amount of interest had been brought to bear upon the question, in some measure due to observations made by gentlemen occupying positions in the political world who were possibly very much at a loss for a subject upon which to speak. An address was delivered recently on the subject of fruit-growing, but those people spoken of as having made £5 a year out of twenty chickens or a patch of Strawberries might be a little disappointed if they tried the experiment. Nor was it to be expected that in the cultivation of fruit they would find the panacea for the trouble which has been afflicting the agricultural classes. The utmost that could be expected was that it would afford some assistance by increased intelligence and skill. So long as we continued to import fruit to the amount of £6,000,000 or £7,000,000 a year people would quote the fact as an evidence of what might be done in this country; but it should not be forgotten that a very large proportion of that amount represented fruit which could not be grown in this country. Since he had been in the gardens of the Society he had asked two authorities what they thought on the subject of cultivating Apples and Pears for profit. One of those gentlemen told him that after the care expended upon them and the cost the profit would not be more than 6d. per sieve, but the other said he was certain that for all the hardy fruit that could be grown in this country a good market could be found. When these fruit Shows were held an attempt was made to collect every description of known Apples and Pears with a view to getting rid of those which were of little value, but the present Conference proposed to invite the cultivation of such only as found favour and might be worthy of cultivation. The object of the Conference was therefore a practical one, and the Exhibition, having regard to the bad season, must be considered satisfactory. One point of great importance was undoubtedly the question of railway rates, and in regard to the step which had been taken in the matter, he thought the Legislature had acted wisely in deciding that preferential rates should be considered and revised by the Board of Trade, because all were painfully aware how the railways had had the monopoly of the means of transport in this country. As a result of the Conference, attacks had been made upon the nurserymen. It was said that they kept a large quantity of worthless Apple and Pear trees, and no doubt such was the case, but they did not represent the bad as good. He was quite certain with regard to the cultivation of hardy fruit that care and intelligence were of much more importance to the result than climate. An evidence of this was to be found in the fact that at the

former show some of the best exhibits came from the north of Scotland.

On the motion of Mr. Shirley Hibberd, seconded by Mr. Cheal, a vote of thanks was accorded to the Chairman and the Council, who, in responding, called attention to the fact that the exhibits on this occasion were much more carefully named than in 1883 and 1885, which showed that the people were beginning to understand their business better. The Show was then formally opened to the public.

On Wednesday the Conference was opened at 1.30 P.M., Dr. R. Hogg in the chair, when after a few introductory remarks, the following papers were read:—

APPLES FOR PROFIT.

By MR. GEORGE BUNYARD, NURSERYMAN, MAIDSTONE.

THE commercial growth of Apples for market is frequently entered upon in a wrong manner, because many start into the enterprise without sound information. Beginners fight shy of the growers of trees for sale under the unfair notion that they would recommend those kinds of which they held a stock; they then procure the "tip" from the salesmen in the various markets, who, as far as they can (and in good faith), give them the names of the kinds that sell well, fruits, so to speak, which dispose of themselves by their names or appearance. Many of the choicest Apples produce but a small crop, or are so long in coming to a state of profitable production that planters get discouraged, others are recommended which are very slow growers or rarely make good orchard trees, and thus land is not fully utilised. As the markets are supplied from a large area, the salesmen have but a general idea of the suitability of sorts to a district, and hence much valuable time is lost. In the short time at my disposal I propose to give a few hints as to the formation of a profitable Apple orchard or plantation, where the return shall be speedy and yet in the future for a century shall promise a good result. The first operation is the procuring of suitable land. In a district where little fruit is grown, an idea can be gained from the growth of the few fruit trees in the cottage gardens, and perhaps the orchards near gentlemen's seats. If the Apples show a kindly and clean growth, with an absence of lichens and canker, and if Elm trees flourish it will so far be favourable. Exposure to prevailing winds is to be avoided either by shelter planting, or better still by taking advantage of existing woods or hedges, and a slope to the south or west is to be preferred, but in order to secure a permanent orchard care must be taken to get deeply cultivated or rich deep soil, or a few years of fertility will only be the precursor of decay and disappointment.

Having settled on suitable land, the tenant or purchaser next proceeds to put the land in order for planting, either by steam cultivation or by thorough digging or trenching. The latter, though expensive at the start, is of permanent benefit. This operation is best done before the frosts set in, that the land may be purified and sweetened by exposure. The ground should then be set out, and standard trees, on the Crab or free stock, of the following sorts, planted 24 feet apart; requiring seventy-five to an acre.

APPLES FOR STANDARD ON WARM LOAMY SOILS.

1, Dessert; to pick and sell from the tree.

August.	September.
Devonshire Quarrenden.	Lady Sudeley.
Sugar-loaf Pippin.	Yellow Ingestrie.

2, To store October to Christmas.

King of the Pippins.	Cox's Orange Pippin.
Mabbott's Pearmain.	Blenheim Pippin.

3, Kitchen Apples to sell from the tree August and September.

Early Julien.	Keswick Codlin.
Lord Suffield.	Duchess of Oldenburg.
Counsellor.	Grenadier (true).
Ecklinville Seedling.	

4, To store October to December.

Warner's King.	Golden Noble.
Schoolmaster.	Tower of Glamis.
Lord Derby.	Waltham Abbey.

5, To keep from January to May.

Wellington (Dumelow's Seedling)	Lady Henniker.
Winter Queening.	Bramley's Seedling.
Norfolk Beefing.	Annie Elizabeth.

If the soil is cold but rich, omit Suffield and add Lord Grosvenor, and omit Cox's Orange and King of Pippins.

So far for the top crop, the space between being utilised by placing three two or three-year-old dwarf trees between each standard, others at 6 feet apart, which, less seventy-five for standards, will be 1135 per acre until the plantation is filled up. These dwarfs will produce

the best fruit from trees on the Paradise or surface-rooting stock, and may consist of the following.

APPLES FOR BUSH OR FREE PYRAMIDAL STYLE TO BE GROWN ON PARADISE STOCKS.

6, Dessert kinds to sell from the tree.

7, Early.	September.
Gladstone.	Col. Vaughan.
Red Juneating.	Duchess' Favourite.
	Worcester Pearmain.
	Duchess of Oldenburg.
	Yellow Ingestrie.

8, To store for sale October to February.

Cox's Orange Pippin.	Gaseoyne's Scarlet.
Cox's Pomona.	Beauty of Kent.
Peasgood's Nonesuch.	Baumann's Reinette.

If the soil is cold omit Cox's Orange and Worcesters, and if very rich and good warm land, add Adams' and Hubbard's Pearmain, Ross Nonpareil, and Gipsy King, while for very late keeping, Golden Knob, Sturmer Pippin, and the smaller fruit of Dutch Mignonne are useful.

9, Kitchen Apples of large size to sell from the tree (on dwarfs).

Lord Grosvenor.	Golden Spire.
Ecklinville Seedling.	Grenadier.
Manks Codlin.	Counsellor.
Pott's Seedling.	Loddington.
Stirling Castle.	Small's Admirable.
The Queen.	

10, Fine kitchen Apples to store (on dwarfs):—

Lord Derby.	Lane's Prince Albert.
Murfit's Seedling.	Bismarck.
Winter Peach.	Dutch Mignonne.*

In six years' time the trees immediately beneath the standards can be transferred to other land, and will if removed with care (in October or early in November), suffer little from lifting, and in the second year will produce heavy crops. After the sixth season the orchard should be left with a permanent crop of dwarf Apples, and standards at 12 feet apart. The dwarfs at some future time could be cut away and the standards, which would then be established and strong, should be laid to grass, and thus fodder for sheep keep and a top crop of Apples could be secured annually. Until the 6-foot trees cover the land Potatoes may be grown between the rows, or Lily of the Valley, or Daffodils. But if land is cheap the space may remain without a crop, and the roots will benefit greatly from the run of all the land. Weeds must be kept down. If standards only are planted no corn crop must be taken, but in this case soft fruit may be placed beneath them. The plantation should be dug in December or January each year, and be knocked over with a prong hoe in March.

Oxen and horses should not be allowed in young orchards. Shelter can be quickly obtained by planting Damsons or Bush Plums (the latter a Kent sort) with Crawford or Hesse Pears as an inner line at 12 feet apart, and this screen would pay its way. If desired, Plums could be placed between the Apple standards, and Gooseberries and Currants, omitting the dwarf Apples. If the land is properly prepared the Apples should need no manure for some years, as the use of stimulants while the trees are young is prejudicial by inducing a sappy unripened growth, which lays the tree open to damage by frost. When the trees are carrying a heavy crop, mulching may be carried out in June, or liquid manure can be used with advantage in the growing time. Such a plantation as described would commence to bring a return from the dwarfs in two years, and the fruit with a little care in thinning would command a ready sale, because when grown in this manner it is cleaner in appearance and much larger in size. In three or four years the standards would commence to fruit, and a much larger return would annually be made, and if properly managed, at the end of fourteen years, the crop would buy the fee simple of the land outright.

In order to make the highest prices, all fruits should be "graded," as the Americans say, and be of an even sample throughout, be properly named, and packed carefully, so that the baskets open clean and bright at the market. In the case of choice dessert kinds it would probably pay to pack them in light card boxes, such as those introduced by Mr. Tallerman for Cherries, &c., and manufactured by Messrs. Johnson. In fact, we should take a leaf out of the French books, and put up our produce in an attractive form. The pruning of the Apples in February or March is of the simplest. No Apples should be pruned the first year of

* The list of fruits given is more extended than is advisable but it may only be possible to obtain a part of the sorts given in the planter's locality. The fewer kinds used the better.

planting. For the first two years commence to form the standard trees by taking out all the inner wood to attain a bowl shape, and cut back the young growth to four or six small eyes, to a bud pointing outward; the fourth or fifth year shorten the wood of the current year to 6 or 12 inches, and keep the centres clear, and after that time let them grow as they like, merely shortening the tips to procure an evenly balanced head, and taking out any crossing pieces of growth. The dwarfs can be cut in to form pyramids or basins, as desired, for two years, and after that be allowed to grow freely. Other matters, such as securing the limbs in a heavy crop, and staking the standards, will have to be attended to, and the stakes must be removed from the standards in the winter as soon as the trees can do without support, as the ties are apt to cut into the bark and produce canker.

For Apple growing land need not be contiguous to a railway station, as they will travel well if carefully packed. Storing enables a grower to realise a high price at a time when good Apples are scarce; where proper stores, such as the Hop oasts of Kent do not exist, a frost-proof shed will do, and if care is taken to store all sound fruit a thick covering of straw will effectually exclude frost and keep the fruit plump and heavy. If 1100 trees bore half a gallon each at three years old the crop would be about 70 bushels per acre, which at 4s. nett (carriage and salesmen's charges deducted) would give a return of £14 per acre; at five years one gallon each would double the produce, and so on. When the top and bottom crop come to pick an average of half a bushel per tree would give a return of about £120 per acre. The risk of loss by wind is small with dwarf trees, and the cost of picking is less than in tall trees, and they can be readily thinned and attended to.

A word as to old existing orchards. My text is—Woodman spare that tree. If such old trees are well manured in two years they would be either producing good fruit, or, if cider Apples, they would so benefit from the improved culture that they should pay for regrafting with superior kinds. I believe much may be done in this way, as the roots soon respond to generous treatment, and the foundation of success rests upon them. Suitable kinds for grafting old trees would be Loddington, Laue's Prince Albert, Small's Admirable, the new and splendid Bismarck, or the smaller dessert Apples, such as Duchess's Favourite and Yellow Ingestrie.

FRUIT CULTURE FOR PROFIT IN THE OPEN AIR IN ENGLAND.

By MR. WILLIAM PAUL, F.L.S.

I THINK I may safely assume that a much larger quantity of English fruit would meet with a ready sale if put before the public in a tempting state. I think I may also assume that there are thousands of acres of land in Great Britain at present bringing little or no profit to owners or occupiers, which, if planted with fruit trees, might be made to return a good profit to both. Not that I think large fortunes are to be made by the venture, but a fair remuneration for the outlay of capital and the application of industry and skill.

To give these opinions a practical application, I propose to say a few words on the subjects under the following heads:—

- | | |
|--------------|-----------|
| 1, Climate. | 2, Soils. |
| 3, Holdings. | 4, Sorts. |

1, CLIMATE.—A mild equable climate free from sudden changes of temperature and storms of wind or rain should be taken in preference. I do not believe in planting Apples, Pears, Cherries, and Plums in the bottom of valleys. This is often done on account of the quality of the soil. But it is of little benefit to the grower to realise a good growth and abundant flowering if his crop is destroyed in the flowering state by the spring frosts. Over the last few years there has been a wonderful show of blossom on the fruit trees in the Valley of the Lea, but little fruit has followed owing to the destruction of the embryo by the severity of the spring frosts in this low situation. This is the one point in climate that would seem to render it unsuitable for culture for profit, as it can be but partially amended by shelter or any other means.

It seems to me that many important points desirable to secure success, which are well known to those who are thoroughly versed in these matters, have not yet taken hold of the general mind, and they cannot be too often repeated till they do this. Only a few years ago I was surprised to meet with an orchard newly planted in the bottom of a moist valley, the climate of which in spring was trying in the extreme for early buds and blossoms. The sorts, too, were indifferently chosen. Nevertheless the planter persevered with their culture, until he found for three or four years in succession he got plenty of blossom but little or no fruit. He has recently destroyed them and cropped the ground

with vegetables. But what a waste of time and money, and what a source of vexation and disappointment.

I believe in planting on slopes or uplands, where the spring frosts are less destructive, with distant shelter to be provided, if not already existing. If cheap, quick-growing trees are planted for shelter within a few yards of the boundaries of the plantations, at the time young fruit trees are planted, the former will afford the necessary shelter by the time the fruit trees come into bearing.

On a farm of 200 acres there may be a difference of climate that would render fruit culture profitable or unprofitable, according to the position in which the trees are planted. In the Valley of the Lea I find that in some years the crop is mainly or wholly on the bottom, and in others on the top of the trees. This I attribute to the frost being more severe in the one case near the ground, and in the other at a greater elevation during the period of flowering.

2. SOILS.—A light or medium loam of good depth and well drained is generally accepted as the most favourable for the production of an abundance of good fruit. It matters not if it be poor, provided manure can be obtained at an easy distance or at a cheap rate. A bad soil in a good climate often yields the grower more profitable results than a good soil in a bad climate. If the ground be wet, thorough and deep drainage is an essential condition of land to be employed in fruit culture, for it improves the climate as well as the soil. Chalk or gravel would seem to be a better subsoil than clay, as the latter, especially if wet, favours the development of canker.

As to soils for the different fruits I would prefer for Apples a medium loam; for Plums, Pears, and Cherries a light warm loam. For Strawberries a light rich loam, cool and moist, with ready access to water. For Raspberries a deep, light loam, also cool and moist. For Gooseberries and Currants a deep, strong loam. But I would not convey the impression that these soils are necessary; in well-drained soils cultivation may be safely extended even to strong or clayey loams.

Of course, the working of the soil is, or should be, much more costly than in ordinary farm operations, and the cultivation of the trees by pruning and keeping free from insects is also an item of cost in labour which must not be lost sight of. In estimates of profits lately put forward it appears to me that these facts in connection with the cultivation of trees and soil have not been sufficiently allowed for.

3. HOLDINGS.—It is often said one should not plant fruit trees for profit except on his own land. But this would unnecessarily limit the number of growers. A long lease, however, is indispensable. According to calculations I have made, but with which I need not trouble you, thirty years is the shortest lease I should advise anyone to plant under. If the lease be for a shorter period I think the tenant should expect from the landlord either a renewal at the same rent as before, or that his trees be taken at a valuation.

It may be thought by some that this is asking too much from the owner of the soil, but I do not think it is more than it is his interest to concede. By such concession he may secure a good tenant and a good rent, and there is ample security for his rent in the value of the trees on the soil. I will read a brief extract from a recent number of the *Sussex Advertiser* in reference to land tenure in Kent, and without offering any opinion on the course taken by the tenant, as I know nothing of the case beyond what is here stated, I think you will all agree with me that such a state of things is to be deplored.

"LAND TENURE IN KENT.—One of the results of the unsatisfactory system of land tenure now prevailing in this country is to be seen at Knockholt, Kent. The lease held by Mr. Edwin Bath of Curry Farm, in that parish, expires at Michaelmas, and he is not allowed to renew his tenancy, nor can he recover compensation from his landlord for a valuable plantation of thirty acres of Raspberries on the farm. Consequently, the extraordinary spectacle may now be seen of a reaping machine cutting down and a steam plough following it rooting up this plantation, which has cost a large expenditure of time and money to produce. When it is considered that the produce of the plantation in question realised in the present year upwards of £1690, and that the plantation was vigorous and in full bearing, some idea may be formed of the sacrifice of property involved."

Further: It has often struck me that the manner in which the charges on land are levied is not equitable, and is calculated to discourage rather than encourage the planting of fruit trees for profit. A few words will, I think, make this plain. A man plants fruit trees not looking for any quantity of fruit for four years. During that period he receives nothing, or next to nothing, in the shape of produce, although rent charges on land and expenses of cultivation are going on and have to be met. Then when his crop brings him a larger return than ordinary

farm produce would bring, the charges on the land are raised! Now it would seem only fair if the charges on land are calculated according to value of the annual crop the planter of fruit trees should pay nothing for the first four years.

4, SORTS.—Of large fruit grown for profit Apples would seem to stand first, Plums next, then Pears, then Cherries. Of small fruits, Strawberries, Raspberries, Currants, and Gooseberries are the most important; Filberts may also be planted to give a profitable crop in odd sheltered spots where other fruits would not grow well. But these different fruits do not all require precisely the same climate and soil. The Apple is perhaps the least particular in these respects, some varieties of which will thrive and produce large crops of good fruit in almost any well-drained soil when grafted or budded on the Crab or Apple stock. The Paradise stock I have found next to useless under field culture on the clayey soils of Sussex. There are fifteen sorts of Apples which I should plant in preference to others in my own county (Hertfordshire), having an eye to the disposal of the crop as well as to its production. They are—Blenheim Orange, Cox's Orange Pippin, Cox's Pomona, Devonshire Quarrenden, Ecklinville, Ducbess of Oldenburgh, Irish Peach, Keswick Codlin, King of the Pippins, Lord Suffield, Small's Admirable, Stirling Castle, Sturmer Pippin, Warner's King, and Wellington.

I can speak favourably of the Ecklinville from experiments made both in Herts and Sussex. I planted in Sussex four years ago 200 Ecklinville Apples that had been cut back as maidens to 2½ feet. The soil (a quarter of an acre) was good, and had been subsoiled 18 inches deep a few years previously. They grew well. The third year they produced 5 bushels, the fourth year 17 bushels, which sold on the ground 5s. per bushel. They were planted about 6 feet by 6 feet, but strong growers might be planted 9 feet by 9 feet, and small fruits or vegetables might be grown between the trees for a few years. I estimate the expenses of planting and cultivating these 200 Ecklinville Apple trees on a quarter of an acre of ground in 1884 as follows:—

Cost of trees, 200 at 50s. per hundred	£5 0 0
Planting and digging	0 15 0
Four years' cultivation, at 15s. per year	3 0 0
Rent, rates, &c., at 10s. per year	2 0 0

£10 15 0

Returns in 1888:—

Twenty-two bushels of Apples sold on the ground, at 5s. per bushel	£5 10 0
---	---------

£5 5 0

Next year I expect to get the outlay back, and look to the future for profits.

In exposed situations pyramid or bush trees are preferable to standards, because the fruit is not so liable to be blown down, and in large orchards, if the trees have stems 2½ to 3 feet, sheep could run under them to feed, and thus help the returns.

PLUMS.—The Early Prolific, Early Orleans, The Czar, Belgian, and the Victoria are good ones. Purple and Pershore Damsons also, of which the Farleigh is well to the front, are usually a profitable crop.

PEARS want a better climate and a warmer, richer, and deeper soil than Apples, and are not usually so profitable a crop as Apples. They do well as a rule on a subsoil of chalk. Of Pears, Aston Town, Eyewood, Hessle, Williams' Bon Chrétien, Beurré de Capiaumont, and Beurré d'Amanlis are the most profitable sorts to grow in Hertfordshire; Louise Bonne of Jersey, where it will grow, and Marie Louise, where it will bear freely, are also good varieties.

CHERRIES like a light and deeper soil than Apples. The May Duke, Bigarreau, Napoleon, and Kentish are good sorts.

STRAWBERRIES.—Vicomtesse Hericart de Thury, Sir J. Paxton, Elton Pine, President, Sir Chas. Napier.

RASPBERRIES.—Carter's Prolific, Fastolf.

CURRANTS.—Black Naples, Lee's Prolific, Red Dutch.

GOOSEBERRIES.—Whitesmith, Warrington, Crown Bob, Lancashire Lad.

In selecting sorts of fruits it should not be lost sight of that some sorts flower later than others, and the blossoms of some sorts are more frost proof than others, and thus the crop is often saved by late-flowering or frost-resisting blossoms. If I were about to plant fruit trees for profit I should look closely to these matters in the selection of sorts. I would also examine all the fruit trees and talk to all the practical gardeners in the neighbourhood whom I could persuade to listen to ascertain which sorts produced the best and most certain crops in the district.

In conclusion, let me say that the grower's work is only partly done

when he gathers his crops. He has to sell them. Like other men of business he must be sufficiently intelligent, industrious and energetic to find the best market for them, and to pack them properly, if packing is needed, or he misses the reward of his skill and labour.

DESSERT PEARS.

THE FEWEST NECESSARY TO SUPPLY RIPE FRUIT FROM AUGUST TO MARCH.

By MR. W. WILDSMITH, HECKFIELD, HANTS.

THE subject of this paper was suggested to my mind by the controversy anent the reduction of the varieties of fruits—Pears in particular—that took place in one of the horticultural journals a few months since. The general tone of that discussion went to show that there was a unanimous feeling in favour of reducing the number of varieties, but to what extent opinions differed greatly, twelve being suggested by more than one writer as the maximum number of varieties, a proposition that in some respects I had a good deal of sympathy with, but the number twelve cuded so far as I was concerned simply because I knew from years of experience that no twelve kinds that could be named by the greatest expert in Pear lore would suffice to give an unbroken succession of ripe fruit throughout the Pear season, say from beginning of August to middle of March. That twelve kinds might be selected that would extend over the Pear season is quite another matter. I have long had the honour to serve an employer whose favourite fruit is the Pear, and consequently have had to give special attention to it, and if one point more than another has had to be studied it is that of quality, a solitary flavourless fruit of an otherwise good variety has not unseldom been the cause of the condemnation of the variety generally. I name this to show that my experience has been gained at some cost of labour and anxiety, and at the risk of being considered egotistical I think this entitles me to speak with some degree of confidence anent this matter of limitation of sorts. Every fruit grower knows how precarious and how variable the Pear is in different soils, aspects, and positions, and no twelve kinds, however good they may be in one garden or district, will be equally so in another, even but a mile or two away, nor even in the same garden can they be relied on to be of the same excellence any two consecutive years, and it is this precariousness that I think renders it necessary to grow a goodly number of varieties. For the purpose of this paper I have closely examined the Pear notes in my diary for several years, in which is noted date of gathering, of ripening, and duration—i.e., time they continued fit for table, and from these notes I have compiled a list of twelve that, supposing I was compelled to grow only that number of kinds, would be likely to give me the most regular (not constant) succession of fruit. They are placed in the order in which they ripened here. Williams' Bon Chrétien, Fondante d'Automne, Beurré Superfin, Marie Louise, Thompson's, Doyenné du Comice, Glou Morceau, Winter Nelis, Josephine de Malines, Huyshe's Victoria, Easter Beurré, and Bergamotte Esperen.

These twelve constitute the cream of all the varieties (nearly one hundred) that are grown here, and out of the twelve there are but two that are at all liable to prove of doubtful quality, and this from a cause over which we have no control—namely, a sunless season. The two kinds in question are Easter Beurré and Bergamotte Esperen, both of them late varieties, and requiring a longer season of sunshine than the others. I may, however, add that I have occasionally in a sunless season had recourse to means that has tended to make both of the kinds palatable—namely, by wrapping the fruit separately in tissue paper, and placing them in shallow baskets in a dry warm room for ten days or a fortnight before the fruit were required for use. And now with respect to the question of the number of varieties "necessary to ensure a continuous supply of ripe fruit." I have, after considerable deliberation, founded on the practical experience of many years, come to the conclusion that it is next to impossible to accomplish the feat with a less number than twenty-five varieties. To some this number may appear excessive, and to such I ought to explain that my experience is given from the standpoint of a private gentleman's gardener—say of a large garden—and from which liberal supplies of Pears are demanded the season through, and therefore it is necessary to have, as it were, two strings to one bow; as, for instance, if Williams' Bon Chrétien Pear run short, I ought to have Beurré de l'Assomption to supply the lack; or if Marie Louise be scarce, I must eke out with Beurré Bosc, and so on, to the end of the chapter.

I regret that I have not practically tested with how few it is possible to keep up a constant supply, but I am sure I should fail if I undertook the task with a less number than twenty-five, and the following are their names, and placed in order of ripening:—Souvenir du Congrès,

Williams' Bon Chrétien, Beurré d'Amanlis, Fondante d'Automne, Louise Bonne of Jersey, Madame Treyve, Beurré Hardy, Beurré Superfin, Seckle, Marie Louise, Doyenne du Comice, Thompson's, Duchesse d'Angoulême, Glou Morceau, Winter Nelis, Comte de Lamy, Beurré Bachelier, Josephine de Malines, Winter Crassanne, Huyshe's Victoria, Olivier de Serres, Easter Beurré, Nec Plus Meuris, Knight's Monarch, and Bergamotte Esperen. All these are generally well known varieties in most parts of Britain, proof sufficient, I think, of their excellence; and I can vouch for their reliability for this district in respect of constant and free bearing and their high quality.

The least meritorious in the list are:—Madame Treyve (quickly over), Duchesse d'Angoulême (gritty), Beurre Bachelier (mealy), and Nec Plus Meuris (also gritty), yet I know no other four kinds that can—all points considered—replace them. Lest anyone should conclude from what I have said as to the number of kinds to insure a regular succession of useful fruit that is all that is required to make certain of the supplies, I will undeceive them at once by saying no. There is no fruit that gives better returns for labour expended, and none that more quickly resents the "let alone" policy that one is occasionally compelled to behold. As regards the former, nearly all our trees are grafted on the Quince, from which stock it is no exaggeration to say that we get at least double the fruit that we do from trees on Pear stock, and high feeding is therefore a matter of necessity; but then the labour of applying these manurial mulchings we place as a set-off against that of the time expended in root pruning, that nearly all trees on Pear stock require about every alternate year, and the fruit is neither so numerous nor so well coloured, and not superior in quality. No, if good crops of fruit are expected annually water and mulch, mulch and water, must be the order of the day all through the fruit-swelling season. Those that must by reason of restricted space grow only a few varieties, and whose demands for fruit are, as a matter of course, proportionately restricted, may do something towards lengthening out the supply of ripe fruit by gathering the same variety of Pear at varying intervals of from a week to ten days. The fruit of most varieties—more especially the earlier kinds—will then ripen at similar intervals, and thus the season of ripe fruit be considerably extended. To those that have unlimited room, and can therefore grow the required number of varieties to insure supplies, this piecemeal gathering is not of so much consequence, nevertheless, I strongly advise its being done with any varieties that ripen rapidly, such as Citron des Carmes, Jargonelle, Williams' Bon Chrétien, and Fondante d'Automne.

ON PRUNING.

BY MR. SHIRLEY HIBBERD.

It is commonly asserted in the books, and forms part of the faith of mankind, that pruning tends to augment the vigour of trees, and as a consequence much of the pruning that is done has in view to promote the end predicated for it. There can no longer be entertained by observant men a doubt of the fact that pruning, so far from augmenting, actually diminishes the vigour of the subjects operated on, and the one sole reason that the fact is not strikingly illustrated in the outdoor world is that Nature is generous, and accomplishes much in compensation for the injuries that are inflicted by the pruning knife. And because Nature is generous and compensative, a certain amount of pruning may be done without harm, and, as regards the objects we have in view in pruning fruit trees, with positive benefit. But so long as we keep in mind that pruning in the abstract is objectionable, we shall be careful to prune in a way to ensure a maximum of the advantage for ourselves, with a minimum of disadvantage to the trees.

Keeping this in mind, we may at once compare the several forms of trees with a view to arrive at conclusions as to their relative values. For the present we will compare the standards, the pyramids, and the bushes. We must deal with them generally, and make broad comparisons, for particular cases would require particular consideration that would be scarcely possible in connection with this Conference.

We will begin with standard orchard trees that bear abundantly, as many orchard trees do. It will be observed that pruning neither augments the vigour of the trees nor does it promote their fruitfulness, for as, generally speaking, they are not pruned at all, they teach a bold lesson of the non-necessity of pruning. Now we will turn to the perfect pyramids, say of Apples and Pears, formed to an ideal model by long years of pruning and pinching. As pyramids they are perfect, being of even contour, dense with foliage, with scarcely room anywhere to allow one to thrust a hand in, and they are healthy and bright from the ground line to the summit. It has to be remarked of these compact leafy trees that they produce so little fruit as but rarely to pay a fair

return for the land they occupy. They do, indeed, occasionally present their owner with a crop, and often he is satisfied. But if we are to take measures for increasing the production of fruit we shall rather avoid than accept trees of this form, or if we must have them we shall, having fruit in view, rather promote an open growth with room to thrust one's head in at many places, this form of tree being favourable to fruit production. We have in our collections many kinds of Apples and Pears that will not, no matter what we do for them, conform to our ideal of the perfect pyramid. It is usual, therefore, to suffer these to grow as open loose bushes, and the difference between them and the pinched pyramids is seen not only in the form and furnishing, but in their superior fruitfulness.

Pursuing the comparison, it will be observed that pruning tends to promote secondary growth that often is immature when the season closes. This growth, therefore, has been obtained by a false system, and its uselessness is a proper commentary on the violence done to Nature. The perfect pyramid is for ever loaded with immature wood that earns nothing, and the density of the foliage so completely excludes the light and air from the wood that fruit spurs are few and commonly unproductive. The free bushes that are not pruned at all, or but moderately pruned, are, as a rule, vastly more fruitful than the pyramids, and the free standards are more faithful than either. Thus, as a matter of fact, the order of fruitfulness is in an inverse ratio to the order of the pruning, and we may conclude that the pruning knife is a deadly enemy to Apples and Pears.

The natural growth of a fruit tree is definite and orderly, but much of our practice appears to proceed on the hypothesis that it is a matter of accident. There is sent forth a certain number of long rods. If these are cut back secondary rods appear, and by stopping these we obtain a lot of soft spray, and so on for ever. But the long rods left to themselves throw out a few side branches and form fruit spurs the greater part of their length. In due time the fruit appears. Often, where the soil and climate favour the business, and the varieties are naturally freebearing, the fruit may be seen to hang like ropes of Onions, while at the same time pruned trees of the self-same sorts are thinly dotted with fruit, so that we can actually count them, which in the other case is impossible. The unpruned standards and bushes are free to follow the course of Nature, and we see them fruiting abundantly and frequently, while the pruned trees fruit scantily and seldom. The obvious lesson is that long rods admitting light and air freely are more serviceable than rods systematically cut back, and thereby compelled to become densely furnished, forming compact trees impervious to light and air, as compared with the free trees, that delight to display their fruits in the fullest exposure. The leading shoots, therefore, should never be shortened except for some special reason.

In the year 1876 I had the honour of reading before the Society of Arts a paper on "Fallacies in Fruit Culture." One of my objects was to demonstrate that systematic pruning and pinching of open ground fruit trees deferred and limited the production of fruit, although these operations were intended to hasten and augment fruit production. And I placed before the meeting for inspection and criticism a number of trees that I had in the first instance selected for their ugliness, but which, having for some years occupied a good soil in a suitable situation, had acquired symmetry and proportion and fruitfulness without aid from the pruning knife, one great point in the business being that every annual growth had been allowed to acquire maturity, no secondary growth being promoted by summer pinching, and no superabundance of furniture resulting from winter pruning. Some of you will remember that in doing this I exposed myself to what I may now recall as a shower of hot shot; but I live still, and repeat the story, and if another dose of hot shot is ready for me I will not flinch so much as to move my eyelids, so sure am I that common sense will at last prevail, and that it will be agreed all round that Nature has something to do with the production of fruit.

I have the consolation, however, of knowing that common sense has prevailed. The horticultural papers altered their tone on the subject of pruning from that date; practical gardeners who lead by intelligence and example saw and acknowledged I was right, and to their advantage they have used the knife less freely than formerly. Moreover, since the year 1876 we have had a succession of Apple and Pear Conferences, and their collective lesson appears to be *Magna est veritas et prevalebit*. For have we not entered on a new career in fruit culture, common sense guiding the way? because only where common sense prevails does Nature prove herself in every sense the friend of man. While we repudiate reason Nature destroys our false work, and does not even stop there, for she destroys man himself, and history is in great part the record of

the price that man has paid for adherence to unreason, superstition and folly.

Amongst the many persons who have carried out my proposals I will name Mr. James Hudson, the gardener at Gunnersbury House, who is known to you, and whose work is near at hand. He had long lamented the unfruitfulness of a collection of good varieties of dessert Pears, but he saw no way to improve them but to continue the practice of pruning. He saw my sample trees in 1876, and from that time he allowed the trees to manage their own affairs, since when they have been constantly and abundantly fruitful. Mr. J. James, then gardener at Redlees, took a similar course and secured equally happy results. In this garden of the Royal Horticultural Society you may see collections of pyramid

lately at Heckfield, Mr. Wildsmith pointed out some Pear trees under reverse training that proved more than ordinarily fruitful. This reverse training does not pay when it is carried out in a severe manner by the aid of the knife and a multiplicity of ligatures, for that system is a mere warfare against Nature, which can never pay. It is in this case practised in a coaxing kind of way: the trees know but little of the knife, and the long rods are brought down gently, as I suggested years ago in what I termed "pulley pruning." Many fruitful trees acquire a half-weeping habit from the mere effect of the weight of the fruit which brings down the branches. There is no merit in observing this, but there is merit in taking from the fact a lesson in cultivation. The reverse position of the branch checks growth, exposes the wood and the fruit

FIG. 41.—THE CHISWICK TOMATO HOUSE. (See page 351.)

Pears that have been systematically summer pruned for any number of years, and have borne moderate crops intermittently. But you may also see a collection of Apple trees in the form of free bushes that have only been lightly winter pruned to keep them somewhat in order, and they have been constantly and abundantly fruitful, and, in fact, have every year for several years past illustrated my idea of fruits displayed like ropes of Onions. In the famous garden at Calcot near Reading, where the late Mr. Richard Webb had every year finer crops of fruit than, probably, could be found in any garden of similar extent in all the home counties, there was absolutely no pruning practised; the trees never made more than a moderate growth, though in land of great strength, and the fruit was of such quality that Mr. Webb took a high place in great exhibitions as well as in Covent Garden Market. When

most completely to the sun and the air, and we may say the mere fact of fruitfulness is promotive of fruitfulness, the half-weeping habit that the law of gravitation enforces on the tree exactly suits its constitution as a fruit producer. Very much of the prevailing practice in pruning promotes rigidity of growth, and compels the tree to be a mere leaf producer.

Now to conclude. Observation and experience have taught me that summer pruning is too promotive of useless secondary growth to be advantageous; and it tends also to keep the roots in action until late in the year, when they ought to be at rest. The effort of the tree to ripen useless wood is detrimental to its more profitable duties. Prune immediately after the fruit is gathered, first cutting out all dead wood, then cutting out cross and ill-placed shoots that would interfere with

the free play of light and air, and then conceal the pruning knife lest anyone should venture to cut back the long rods, and so renew the old warfare between useless wood and useful fruit.

Pyramid trees of many sorts of Pears will acquire beauty of contour, and become regularly furnished, and will produce abundance of fruit without any pruning whatever, as I have shown by my trees that for fifteen years continuously were never touched with the knife. The lower branches of pyramid trees never bear fruit, probably from proximity to the ground and its exhalations, as well as from the low temperature that often prevails at that level. When left to form themselves, or aided in quite an infinitesimal degree, they remain open to light and air, and soon become well clothed with spurs that ripen perfectly and do their duty. The dense, leafy pyramids are useless in proportion to their leafiness, and very often it may be said that the free bushes and standards are useful in proportion to their leanness, and it must be owned that many of the lean trees are amongst the most profitable. Long rods pay, short rods are more plague than profit.

A most instructive contrast between the useless pyramids and profitable standards has occurred in the garden planted many years since by my friend, Mr. J. B. Saunders, then of The Laurels, Taunton, now of Teignmouth. Mr. Saunders was proud of his pinched pyramid trees, and managed them with orthodox care. They were but moderately fruitful, though models of form, and as handsome in leafage as Camellias. In the course of time, my friend having left Taunton, a portion of his beautiful garden, of which many of the pyramid trees were occupants, came into the possession of Mr. Godding, nurseryman, of that town. This gentleman soon discovered that the pyramids would never pay rent for the land they covered, and he determined that they should pay liberally, and cover no land at all. He cut them back to sheer stems of 7 to 10 feet or so, according to their form and stature, and allowed them to form free heads over the gravel walks. They have done this; he crops the borders under them to their very stems, and they arch over the walks, forming rustic bowers, and their fruitfulness is such that it is necessary to provide artificial support to save them from self-destruction. You have never seen pinched pyramids in the deplorable condition of needing artificial support.

Of wall and cordon trees I do not propose to say anything at this time, except that they must be amenable to common sense, and Nature must have some freedom even where the trees are so fettered. Of one thing I am satisfied, that any system of pruning that promotes a late summer growth is pernicious, for it is not in this climate that fruit trees can make and mature useful wood after the passing of Midsummer Day.

CHRYSANTHEMUMS IN THE METROPOLIS.

THE annual public display of Chrysanthemums in the Inner Temple Gardens, under the charge of Mr. Newton, will by the permission of the Benchers, be opened to-day (Thursday). The plants are looking very promising, and some of the earlier varieties are already in flower, but they will not be in their best condition before the end of the month. The Chrysanthemum Show in Finsbury Park, which for several years now has attracted so many visitors, will be opened on Saturday, October 20th. We had the pleasure of seeing the large stock of plants a few weeks ago, and they were then looking exceedingly well indeed; it seemed as if previous successes were likely to be surpassed this season. The collections at both places include examples of the best old and new varieties.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE usual autumn general meeting of members took place at Anderton's Hotel, Fleet Street, E.C., on Monday evening, the 15th inst., Mr. E. Sanderson, President, in the chair, among those present being Messrs. R. Ballantine (Vice-President), E. C. Jukes, C. Harman Payne, G. Stevens, Blake, R. Dean, G. Gordon, and many other leading supporters of the Society. The minutes of the annual general meeting, held in January last, having been read, the Hon. Secretary, Mr. W. Holmes, reported in reference to the provincial Show of the Society to take place at Sheffield on November 16th and 17th, that the Midland Railway Company had offered to convey exhibits to the Show and back for a single fare, provided they were allowed to remain there all the time the Show was open; also that they were prepared to place at the disposal of those going from London to the Show two saloon carriages, if there were a sufficient number of travellers to justify them in doing so. The

Hon. Secretary also reported that he had paid the sum of £70 in prizes awarded at the September Shows, and four silver medals had been sent to their respective winners. He stated that complaints had reached him from some of the smaller trade growers, that as all the trade classes were open to the large growers, they had but little chance in the competitions. He suggested that in the future the General Committee should name the sum they would be willing to give for Dahlias, and then request representatives of the Dahlia growers to meet and prepare a schedule of prizes, also that they should nominate judges in the Dahlia classes. A hearty vote of thanks was passed to those members who acted as stewards on the occasion of the Show. Mr. C. Harman Payne reported that the labours of those appointed to revise the catalogue of the Society were at an end; that their work had lasted seven months; that the revisers had received valuable assistance from the thirty members of the Catalogue Committee, also from outsiders, and they had made use of those suggestions likely to be of service to the Society. They had followed the programme laid down for their guidance as nearly as possible, and he thought the Society could be congratulated upon the possession of a catalogue of a very valuable character. The Hon. Secretary then moved the following resolutions, which were seconded by Mr. George Stevens, and carried by acclamation:—"That the members of the National Chrysanthemum Society desire to place on record their high appreciation of the very valuable work accomplished by those gentlemen who have prepared and published the 1888 edition of the Society's catalogue. To each of those who constituted the specially selected Committee, and who prepared reports on the several sections consigned to their care, the members tender their very sincere thanks, and especially to the Revision Committee, who received these reports, revised and tabulated the same." Further, "That the silver medal of the Society be duly and suitably engraved, and presented to Messrs. Lewis Castle, George Gordon, and C. Harman Payne, in recognition of the admirable result of their painstaking and arduous work; also, That a copy of this resolution be entered upon the minutes, and a lithographed copy be prepared and furnished to each member of both Committees." It was further proposed by the Hon. Secretary, seconded by Mr. R. Ballantine, and carried unanimously, "That the Society appoint a Permanent Revision Committee, to take such notes as may be necessary with a view to further revision at a future period, and that such Committee consist of Messrs. C. Harman Payne, L. Castle, and G. Gordon." Two new Fellows and sixty-one ordinary members were elected, bringing the total of the latter up to 572. A cordial vote of thanks to the Chairman brought the proceedings to a close.

LADIES' CHALLENGE CUP AT WINCHESTER.

I ENCLOSE an advertisement for the next issue of the Journal, in which you will observe the ladies of Winchester, through the Mayoress, have subscribed for and presented the Society with a very handsome silver challenge cup, value £15, on the express condition that it is offered for competition annually at our autumn show for Chrysanthemums as long as our Society remains in existence; and if at any time the Society should cease to exist it should pass to the Corporation of Winchester, to be disposed of as they should think fit. I should be much obliged by the insertion of this paragraph in the Journal, as the time is drawing somewhat near. Trusting that we shall have a good show season.—CHALONER SHENTON, *Hon. Secretary Winchester Horticultural Society.*

CHRYSANTHEMUM MRS. BURRELL—EARLY FLOWERING.

PERMIT me to recommend your correspondent who inquires about the best early flowering Chrysanthemums to add this to his list. It is a deep primrose yellow, and, if I remember aright, a "sport" from the very useful *Mdme. Desgranges*, but I do not know its origin—perhaps you would say. At all events, for most decorative purposes during September and October it can be relied on just as much as its foster-parent aforesaid—if the term can be applied. I saw some fine bunches, evidently of this, in the Waverley Flower Market in Edinburgh, about a month since, while my plants are only flowering now, being grown in the open air until commencing to bloom. I think Mr. Cannell of Swanley, who has given flower lovers so many good things, deserves the credit of having introduced this, but I am speaking from recollection. Here, where there are so many exhibition growers, I am proud to say the frost of the first week in October did little harm.—W. J. MURPHY, *Clonmel.*

CHRYSANTHEMUMS AT PUTNEY.

ALTHOUGH Mr. Stevens grows as many as 10,000 plants for flowering in the St. John's Nursery, Putney, it is surprising how well they look and how few plants there are which do not seem capable of producing good blooms. Besides growing a large general collection for flowering and supplying cuttings later on, large numbers of particular sorts are here cultivated; for instance, *Elaine* is represented by two long rows of about 1000 plants, very healthy and almost as even as a clipped hedge, so uniformly have they grown. The cuttings are rooted early in November; the points are pinched when the plants are 6 inches high, and again at 10 inches high, the result is nine to twelve branches, producing that number of fine blooms which meet with a ready sale. A high opinion has been formed of *M. W. Holmes*, an early flowering Japanese variety, chestnut red, inclining to dark crimson, the florets, which are tipped with gold, rendering it very attractive. The growth of this variety is striking, being robust with good foliage, the height being medium. As many as 800 of this variety are cultivated. Then, again, *Princess Blanche*, which is regarded as one of the best late-

flowering varieties, is represented by about 300 plants, all most promising. Of Lord Eversley, the pure white sport of Princess of Teck, which proved itself such a capital late-flowering variety last season, 400 plants are grown which did not measure more than from 9 to 12 inches high at the time of my visit, these being cut down in the middle of June. These will produce capital dwarf plants late in the season, no doubt. Fine plants of Mdle. Laeroix are commencing to unfold their flowers; particularly dwarf and stocky were they, from 2 feet to 3 feet high, carrying three and four blooms each. The general collection is represented by whole rows of some varieties which are most popular, the whole being systematically arranged in parallel lines, the tallest plants in the centre. The foliage in nearly all cases was particularly healthy and of good texture, the wood stout, short-jointed and hard if not particularly large, just the kind to produce satisfactory results. Noticeable for their good appearance were the Queens, Tecks, Audiguier, Molyneux's.—VISITOR.

THE BRITISH FRUIT GROWERS' ASSOCIATION.

THE adjourned Conference of fruit growers at the Crystal Palace was resumed on Thursday the 11th inst., at 2 P.M., Mr. T. Francis Rivers in the chair, and there was a good attendance of those interested in the movement. The principal business of the meeting was to receive the report of the Executive Committee respecting the formation of an Association. It may be remembered that on September 8th last, at the conclusion of the Conference of fruit growers in the Crystal Palace, Mr. J. Cheal proposed a resolution to the following effect—namely, "That it is desirable an Association of fruit growers should be formed for the promotion of profitable fruit cultivation, and to improve the methods of distribution. The Executive Committee of the Conference being requested to prepare a report on the subject, to be submitted to the next meeting at the Crystal Palace, on October 11th this year." This was seconded by Mr. Fowler and duly carried. In pursuance of this resolution the Executive Committee met at 5 P.M. on Thursday, September 27th, at Anderton's Hotel, Fleet Street, Mr. T. Francis Rivers in the chair, twelve members being present. The Chairman referred to the favourable notices accorded by the daily and horticultural press to the Conference at the Crystal Palace, and it was mentioned that over sixty reports and articles referring to it had been published. A draft of the Association was then read, considered at some length, and finally adopted.

In submitting the draft named to the meeting on Thursday, the Chairman remarked that the inception of this Association was wholly due to Messrs. Gordon and Castle, who a few months since began the organisation of a Society which, he thought, had succeeded in drawing the attention of the people of England to the important fact that a large and lucrative industry was being silently withdrawn from our country, to the great advantage of those who had skilfully taken advantage of our apathy and indifference. The promoters had happily chosen the right time for inviting public attention to the deplorable results which might overtake them. The United States, Canada, Australia, and New Zealand were all on the alert to supply our markets with a commodity which they were supposed to be unable to furnish. Were they to sit by with folded hands and allow this to be done? Were they to complain that their inability was owing to landlords, land laws, railway rates, or middlemen? In his opinion they had nothing to do with it. The profits derived from judicious fruit cultivation were sufficient to cover the moderate and fair rents now asked for land. The real and fundamental cause was ignorance, not arising from want of intelligence or energy, but from the fact that no organised society, school, or college had ever undertaken seriously to teach the methods by which fruit cultivation might become successful. The Royal Agricultural Society had spent vast sums in advancing the interests of agriculture, with the result that it now took the leading rank. He hoped some day that the country would have a Royal Pomological Society. The State spent a large sum on botanical gardens with the most useful result, but it did not at present give any encouragement to an industry which was of serious importance to the land. One of the aims of their Society would be to draw attention to this omission, to rectify their past errors, and to place pomology in the rank which it should take as a science of high economic value. The other aims and objects of the Society would be to invite discussion, to hear papers, and to organise meetings in different parts of the country, in order that a special knowledge of pomology might be diffused as widely as possible, and intending planters furnished with information which would lead to success instead of failure.

Mr. G. Bunyard proposed the adoption of the draft constitution which had been printed and circulated amongst those present. The objects of the British Fruit Growers' Association would be to promote the profitable culture and improvement of fruits in the United Kingdom and to facilitate the distribution to consumers, and he believed that if conducted on the lines laid down in the report of the Committee the Association would be able to render immense service to those engaged in fruit culture. He referred to the statements recently made in a daily paper by an anonymous correspondent respecting the large proportion of worthless trees in nurseries, and on behalf of himself and that of numerous others in the trade he stigmatised the statement as absolutely false. Mr. J. Cheal seconded the proposition, and said there was plenty of room for the Association to do good and useful work.

Mr. Roupell of Roupell Park, Brixton, observed that, in view of the erroneous statement which had appeared in the Press, he desired to say that as an enthusiastic amateur he had given orders to most of the

principal firms of the country, and he was glad to be able to say that they had always furnished him with good trees, true to name.

Mr. R. Dean called the attention of the Chairman to the fact that publications of the National Fruit Growers' League were being distributed at the Conference, reminding him that it was the Secretary of that body who wrote the wicked and scurrilous letter to the *Daily News* to which Mr. Bunyard had referred. (Shame.)

The adoption of the report was then put by the Chairman and carried unanimously. A list of proposed officers was then read, including Mr. Lewis Castle, Hotham House, Merton, and Mr. Wm. Earley, Ilford, as Hon. Secretaries; and it was announced that the names of over sixty persons desirous of becoming members had been received.

The following paper was by request then read by Mr. J. Wright:—

PROFITABLE FRUIT FARMING — MAINLY GOOSEBERRIES.

A POINT that I have observed at these meetings is a tendency to concentrate attention mainly on fruit-bearing "trees," such as Apples, Plums, and Pears. The importance of those crops, especially, perhaps, the two former, is admitted; and without suggesting that too much attention has been devoted to them, the fact remains that little or nothing has been advanced on the smaller but not less useful, and under certain conditions not less profitable, bush fruits—Currants and Gooseberries. It is to a successful example of growing the latter that I will chiefly direct attention now.

Having been credibly informed that Gooseberries were grown in the fens of Lincolnshire on an extensive scale and with great success pecuniarily—that the bushes were so large that twenty or thirty women could work amongst them without being seen, and that fruit was sent away in tons by rail to London as well as to cities and towns in the north, I thought I would endeavour to see for myself this fruit plantation on a level with the sea, and very few miles from it—a district exposed to the full sweep of the east winds in spring that are often so disastrous to fruit blossom in more or less sheltered inland localities.

A somewhat lengthened experience with fruits, first as a cultivator or worker amongst them for a quarter of a century, and subsequently as an inspector of the work of others in different counties, I never hesitate to journey a hundred or more miles for the purpose of verifying a statement, even though I may be convinced of its truth at the outset.

I am a strong believer in accomplished facts, and have a weakness for seeing them. Now and then some of the actualities of culture impress me, and a desire arises to impress the examples on others (who may not have opportunities for a personal examination) in the hope that the recital may possibly be of slight service to persons who have land at disposal and desire to cultivate it profitably.

The combinations in culture that have impressed me during the past few weeks are Gooseberries, with Apples, Pears, and Plums in Lincolnshire, and Apples and Osiers in Nottinghamshire. Some Apples in the Show to-day of Bramley's Seedling remind me of large orchards of it with their undergrowth of Osiers. When you see say twenty acres of Osiers 6 or 7 feet high, and standard Apples growing amongst them, their heads, as it were, resting on the Osiers and stems invisible, and both Apples and Osiers growing in the most satisfactory manner as if they took different food out of the soil, as perhaps they do; when you see that, I say, as it may be seen near Southwell, I think you will not forget it, and when you learn that the land so occupied has increased in value from £25 to £100 an acre in half a dozen years, some of you would perhaps not object to have a share in the little enterprise. This, however, is a digression, and as more will certainly be heard about this Apple and Osier culture, and as information can be obtained any day from Mr. Henry Merryweather, we will pass on to the Gooseberries.

Those to be referred to are at Pinchbeck, a large parish of 11,000 acres as level as the sea, the soil of medium texture, yet free working, alluvial, probably rich in phosphates, as old sea beds usually are, and resting on—well, apparently on water, for, judging by the dividing ditches, the water table appears to be within 3 feet from the surface. Authorities tell us Gooseberries like a dry subsoil. Perhaps they do, for they are very good natured, and are certainly quite content to thrive on a wet one in the Fens. The plantation in question is the property of Mr. Charles Parker, a farmer of 200 or 300 acres. I do not know whether he owns the whole of it or not, but hope he does. Be that as it may, the portion under fruit culture, with the well appointed homestead he has built, is his freehold, the reward of his industry, good management, and enterprise. He is one of those men of whom we ought to be proud in these days, for he makes land pay that is not under fruit culture, though this would be extended if he could make sure of a sufficiency of labour for gathering the crops. What a contrast is here

to what obtains in many districts, where men and women are longing for labour and longing in vain. Mr. Parker employs five times more workpeople on his little farm than hundreds of farmers do who have five times more land than he has, and they grumble at "bad times," while he smokes his pipe in contentment at work well done and in rest well deserved.

I have said he makes land pay that is not under fruit. An instance will suffice—a fine piece of Mangolds, pointed out as showing the superiority of a mixture of sulphate of ammonia and superphosphate over bonemeal, the same in value being applied on different portions of the field. "But," remarked the owner, "the Mangolds are only a second crop." "A second crop!" I repeated, parrot-like and in surprise. "Yes," was the quiet rejoinder, "I made £200 out of the plot this year before the Mangolds were sown." That was a poser to me, for the land would not exceed 4 acres. But what was the wonderful crop? It is a very simple one that you are all familiar with, so I think I will leave you to work it out. Why not? Mr. Parker did, and no one told him; and besides, I think I ought to have his permission before making it known to the world. I have no such reservation about the Gooseberries, they are Crown Bobs, and such bushes of the good old variety as I have never seen elsewhere. Instead of twenty or thirty women working amongst them without being seen gathering the fruit, a hundred might have been so engaged, yet invisible. Several of the bushes were as high as I am, some higher, and all much farther round, while when laden with fruit a few of them may have been nearly as heavy, but perhaps not quite. The yield varies from 30 to 40 tons, and this year the price obtained for them was £10 a ton. It is considerably lower than that when the crops are heavy everywhere. The culture is very profitable, more so, perhaps, and more quickly than any under crop that can be grown in orchards, and more so, also, taking one year with another, than the fruit tree crops above them of Apples, Pears, and Plums, though when all are good alike, as occurs occasionally, they realise a little fortune; but the top crops fail at least every alternate year, and sometimes more frequently, the bottom crop seldom. This is the staple.

The Gooseberries are gathered as soon as they are large enough for use, and are cleared off as quickly as possible, and are sent off in cwt. hampers by the Great Eastern Railway southwards, and the joint Great Northern in the other direction, Pinchbeck station being within a mile from the grounds. Several varieties of Gooseberries have been tried, including the celebrated Whinham's Industry, that is so good in many places, also Whitesmith, this and Lancashire Lad being favourites with many market growers, but Old Bob holds the field in the Fens, and drives all competitors out of it sooner or later. It has also driven out Currants both Red and Black, in bringing more grist to the mill than they did, and that, and that alone, is the test of merit. There is no charm in names and outside reputations with growers like Mr. Parker. That which pays best is retained and increased, the relatively inferior, or less lucrative, being removed, no matter whence they come and what they are called. The bushes are grown on clean single stems raised from disbudded cuttings on the premises. Several used to be sold, but only about 10,000 a year are now disposed of to friends and neighbours. Cuttings inserted with all their buds resulting in a mass of suckers, as is not uncommon in some parts of Kent, would not be tolerated. They are regarded by Mr. Parker not only as slovenly, which they are, but relatively inferior in productiveness to those grown on clean stems, and with no other growths springing from the soil.

Pruning is mainly confined to thinning out any shoots or branches that, if left, would impede the work of clearing the crops. There is no systematic spurring, or of shortening the terminal growths at a prescribed number of inches, but possibly the ends of any that project far beyond the rest are snipped off, for the bushes are not entirely wanting in symmetry. They are creditable in appearance regarding them from a gardener's standard, but are essentially fruit and money producers, and in this most important respect answer their purpose well.

A few words may be added on "top" fruit, in order to complete the description of this simple yet profitable fruit garden. It has been said that Apples, Pears, and Plums are grown. These were planted amongst Gooseberries, or the Gooseberries planted amongst them, I cannot tell which; nor does it matter, because in present routine the removal of both is constantly going on. When trees show signs of failure they are either grafted or uprooted, and old bushes give place to new when the desirability arises.

The larger trees are planted as a rule about 6 yards apart, which suffices for Plums and early Codlin Apples, but not for later Apples of spreading growth. Generally three rows of Gooseberries are grown

between each two rows of trees, a few bushes at about 6 feet apart also being planted in lines with the trees.

No Pears are grown in bulk besides the Hessele, which is one of the hardiest, tallest, and freest growers and abundant bearers, and is well adapted for exposed and cold districts. It is not unusual to gather a hundred pecks from a tree, and there is no difficulty in disposing of all that can be grown. The fruit is neither large nor particularly handsome, but is good, and the crops "pay" well.

Of Plums reliance is placed on Victoria, because the trees always bear, and the fruit always sells. It is the Plum of Plums for northern orchards, and the branches do not break when lopped in occasionally, the trees then making closer heads than is natural to the variety. Treated in that simple way props, that are so numerous in some orchards, are dispensed with.

Apples are by far the most extensively grown as "top" fruit, but though trees are numerous varieties are limited. Keswick Codlins have been long grown, but this and all others of the type are being superseded by the Domino, which grows and bears well in a young state, giving quick returns, the fruit being ready as soon as the Keswicks, while it is larger, darker in colour, heavier, and keeps longer. This Apple is spreading and will spread. A variety not often seen in the south, the Sleeping Beauty, is grown because of its productiveness, for the fruit is not large, and the variety not likely to be greatly increased. Jennings's Seedling, a local Apple, is bearing more heavily than any other, and the fruit being of good size is in demand in the markets. Portions of clean branches of three or four years' growth, cut into lengths of 3 feet or so and firmly inserted in the ground, make fine trees of upright growth. Some of them 20 or 30 feet high were crowded with excellent fruit. Possibly specimens may be sent to Chiswick next week. Dumelow's Seedling has been extensively planted, and for a long time was relied on for late use and was very profitable, but of late years trees of it, old and young, have entirely failed to give satisfaction. They have assumed a sickly appearance from some unknown cause, and this once favourite Apple is "done for" in the district. Its place is being taken by the Nottinghamshire Apple, Bramley's Seedling. Trees planted twelve or fifteen years are models, strong yet sturdy in growth, with dark green leaves and clusters of large glossy green, red flushed fruits of great weight, and which command the top price in the market. This is essentially an orchard Apple that is bound to spread. The trees appear to be intermediate in character between Dumelow's Seedling (also known as Normanton Wonder and Wellington) and Blenheim Pippin, and I should not be surprised if those are the parents. It seems to combine the vigour of the latter with the free spurring character of the former. I have seen 50,000 trees of Bramley's Seedling during the past month, and one bearing a crop for which the owner would not take £5 and be relieved of the gathering. A writer in an evening paper, the *Echo*, alludes to a tree bearing £10 worth of fruit. I have not seen such a mountain of gold, but I have seen upwards of 50 pecks of 18 lbs. on a tree that can be sold any day for 2s. a peck. It is well to see what is going on in the east and north, and to take note of varieties. One I have been told will even outlive Bramley's Seedling, and this is Pearson's (of Chilwell) New Northern Greening. I have seen two-year-old trees of this bearing freely fruits which for symmetry and solidity could not be surpassed. It is a long keeper, worthy of attention, and has undoubtedly a long career of usefulness before it; but as to its surviving its compeer, I feel sure that no person living will witness the end of either, so the question of "durability" must be left to be settled by succeeding generations.

The fashion at present is to plant Apple trees closely together on Paradise stocks for early bearing. Undoubtedly that is the way to get the most Apples in the least time, but I have yet to be convinced, taking into account first cost and after labour (with the contingences of seasons) that a combination of orchard Apples and Plums, with an undergrowth of Gooseberries, will not give an equally good return to a large number of cultivators, not skilled in pinching and pruning, but who yet may send the best of fruit, "top," "bottom," or both, in large bulk to the markets after the manner of the intelligent and thrifty Fen farmer at Pinchbeck.

The proceedings were closed by votes of thanks to the Chairman, the readers of the papers, and the exhibitors of some objects of interest.

CRYSTAL PALACE HARDY FRUIT SHOW.

OCTOBER 11TH TO 13TH.

A VERY satisfactory Exhibition of hardy fruits was held in the Crystal Palace, Sydenham, on Thursday, Friday, and Saturday last.

week, the competitors being more numerous and the quality of the exhibits higher than the majority of experienced visitors expected to see. Apples were especially good, and comprised a good proportion of large or brightly coloured samples. Pears were rather below the average in size except in a few of the leading collections, Mr. C. J. Goldsmith in particular showing remarkably well. Several fine collections of miscellaneous fruits were staged in the Veitch Memorial class, while vegetables were most extensively and well represented. The exhibits were most conveniently and effectively arranged under the direction of Mr. W. G. Head upon a series of tables in quadrangles, thus allowing ample space for the visitors instead of confining them to one or two avenues.

We cannot give full details of all the classes as the demands upon our space are heavy this week, and readers will find ample lists of varieties in the subsequent reports. Amongst the open classes that for a collection of Apples was most interesting, a capital display being provided by the four prizewinners—Mr. J. Cranston, Hereford; Mr. J. Watkins, Hereford; Messrs. G. Bunyard & Co., Maidstone; and Mr. C. G. Selater, Exeter, who were placed in the order named. A similar class was provided for Pears, and in that the honours were won by Mr. J. Butler, gardener to A. J. Thomas, Esq., Orchard Lane Gardens, Sittingbourne; Messrs. J. Cheal & Sons, Crawley; Messrs. G. Bunyard & Co.; and Mr. W. H. Chisholm, Oxon Hoath Park, Tunbridge.

The amateur classes were well filled, and the exhibits of considerable merit. With twenty-four dishes of Apples, Mr. J. McKenzie, gardener to F. S. W. Cornwallis, Esq., Linton Park, Maidstone, was first, followed by Mr. A. Waterman, gardener to H. A. Brassey, Esq., Preston Hall, Aylesford, and Mr. S. Ford, Leonard's Lee, Horsham. For twelve dishes of Pears and the same number of Apples Mr. C. J. Goldsmith, gardener to Mrs. C. A. Hoare, Kelsey Manor, Beckenham, was first in both classes, showing admirably grown fruits, such as we are accustomed to seeing from this experienced cultivator. Messrs. Chisholm, Jones, Killick and Jewson followed in the two classes.

The Veitch Memorial prize of £5 and a bronze medal, with three other prizes offered by the Crystal Palace Company, brought five competitors, Mr. J. H. Goodaere, Elvaston Castle Gardens, Derby, winning premier honours with the following Grapes: Gros Colman, good bunches, and berries finely coloured; Muscat of Alexandria, well ripened, and Gros Maroc, even bunches and good colour; a Queen Pine Apple, Braby's Gages, Raby Castle Currants, Filberts, Cox's Pomona, Astrachan, and Worcester Pearmain Apples, Morello Cherries, Read's Scarlet Flesh Melon, Princess of Wales Peaches, very fine; Pitmaston Duchess, Brockworth Park. Souvenir du Congrès, and Williams' Bon Chrétien Pears, Horticultural Prize Melon, Coe's Golden Drop Plum, Warrington Gooseberries, and Brown Turkey Figs. Mr. Pratt, Longleat Gardens, Warminster, was second, showing twenty-one dishes of fruit, a creditable collection. Mr. A. Evans, gardener to S. Hodgson, Esq., Lythe Hill, Haslemere, was third, and Mr. J. W. Reed, gardener to E. Pettitt, Esq., Broadwater, Otlands Park, Weybridge, was fourth.

The special prizes offered by Messrs. Sutton & Sons, Reading, and Mr. T. Laxton, Bedford, together with the prizes provided by the Company and the Turner Memorial prizes, brought an excellent display of vegetables. Gourds and Pumpkins were largely shown, and extra prizes were awarded to Messrs. G. Bunyard & Co., Maidstone, for a handsome collection of market Apples; to Messrs. Sutton & Sons, Reading, for a beautiful collection of seedling Potatoes; to Messrs. J. Laing & Sons, Forest Hill, for a varied collection of Apples and Begonias; to Messrs. H. Cannell & Sons, Swanley, for an excellent collection of Begonias; and to Mr. W. Taylor, Hampton, Middlesex, for a collection of Apples and fruit trees.

EVENTS OF THE WEEK.—To-day (Thursday) the National Apple and Pear Conference in the Royal Horticultural Society's Gardens at Chiswick will be resumed at 1.30 P.M. The papers announced for this day are "Canker in Fruit Trees," by Mr. J. Douglas and Mr. E. Tonks; the "Enemies of the Apple and Pear," by Mr. J. Fraser; "Varieties of Apples for Sussex and their Culture in Heavy Clay Soils," by Mr. J. Cheal; "Renovation of Old and Formation of New Orchards in the Midlands," by Mr. W. Coleman; and "Apples and Pears Suitable for Cultivation in Scotland," by Mr. M. Dunn, Mr. Shirley Hibberd presiding. On Friday the papers to be read are on "Compensation for Orchard Planting," by Mr. W. E. Bear; "Fruit Production and Distribution," by Mr. E. J. Baillie; "Railway Charges for Carriage," by Mr. D. Tallerman, Mr. H. J. Veitch being appointed to preside on the occasion. On Tuesday, October 23rd, the Royal Horticultural Society's Fruit and Floral Committees will meet in the Drill Hall, James Street, Westminster, and the Floral Committee of the National Chrysanthemum Society will meet in the Westminster Aquarium on Wednesday, October 24th.

— **TO CORRESPONDENTS.**—In consequence of the pressure on our columns several communications on various subjects cannot be inserted this week, but they will be published as soon as possible.

— **NATIONAL AURICULA SOCIETY, NATIONAL CARNATION AND PICOTEE SOCIETY.**—The Honorary Secretary informs us that the annual general meeting of the above societies will be held in the room of the Horticultural Club, "Hotel Windsor," Victoria Street, on Tuesday, October 23rd, 1888, at 4 P.M. precisely. The business of the meeting will be the election of officers and committee; receiving the Secretary's and Treasurer's report; the election of Judges for the ensuing year, and any other necessary business as may pertain to the annual general meeting.

— **HORTICULTURAL CLUB.**—The first dinner and *conversazione* for the season 1888–89, took place last Tuesday at the new rooms of the Club, "Hotel Windsor," Victoria Street, Westminster. There was a very large attendance of members, including Mr. John Lee (Chairman), Rev. W. Wilks, Rev. F. H. Gall, Messrs. H. J. Veitch, J. H. Veitch, J. Walker, H. J. Pearson, Chas. Pearson, A. H. Pearson, Bunyard, Rivers, Druery, Girdlestone, Golding, Morris, the Secretary, &c. The subject for discussion was "The Peach," and was opened by Mr. T. Francis Rivers. A discussion afterwards took place, in which Messrs. Lee, Bunyard, H. J. Veitch, Pearson, Golding and others took part. A vote of thanks was offered to Mr. Rivers, and the Secretary announced that in November Mr. Bunyard will read a paper on "November and December Pears," and in December Mr. Pearson one on "Chrysanthemums." Unqualified approbation was bestowed on the arrangements of the Club, and a very agreeable evening was spent.

— **THE NOTTINGHAMSHIRE HORTICULTURAL AND BOTANICAL SOCIETY.**—The monthly meeting of the above Society will be held at the Arboretum Rooms, Nottingham, on Wednesday, October 31st, at 7.30 P.M., when Mr. M. Gleeson, Clumber Park Gardens, Notts, will read a paper on "The Pine Apple," giving a short sketch of the distribution of the plant, its introduction to Europe, and the various methods of its cultivation down to the present time.

— **LAPAGERIA ALBA.**—This fine greenhouse climber is in good condition at Cleveland House, Clapham Park, the residence of S. Ralli, Esq. One plant is most densely flowered, a single bunch containing twenty-three beautiful waxy blooms; it is an object of great beauty. Twelve years ago, when carpet bedding was at the zenith of its popularity, the beds at Cleveland House were amongst the most famous in the country, and although the old order has changed there are many features of interest in the gardens, which are now under the able management of Mr. H. Jackson, on whom their condition reflects the utmost credit.

— **HELENIUM AUTUMNALE.**—I find this a capital yellow flowering companion for the *Pyrethrum uliginosum*. It is of the same vigorous growth, strong clumps forming in the course of two seasons, and flowers slightly earlier. The flowering stems attain a height of about 4 feet, the flowers being produced on a branching head. Fewer flowers are formed, and these have shorter stems than is the case with the *Pyrethrum*, but they are somewhat stouter, and certainly very beautiful in a cut state. It is perfectly hardy, and will grow wherever planted without any further trouble being taken with it, but at the same time pays for a little attention in the shape of lifting, dividing, and replanting the clumps occasionally. —W. I.

— **VIOLET WELLSIANA.**—I enclose you a few flowers and leaves of this beautiful single Violet, which bids fair to eclipse all the other single varieties, and is decidedly the most distinct among them, and its strong vigorous growth, large flowers and foliage, at once arrest everyone's attention. We have been gathering flowers of it since August from unprotected plants, and although we have had 11½° of frost the plants are nothing the worse. It is a fitting companion to the beautiful double variety Marie Louise, and I advise all who have not grown it to do so.—JOSEPH OLIVER, *Eslington Park*. [The flowers received were 1½ inch in diameter, of good form and great substance, borne on stout stalks 7 inches in length. The leaves are 5 inches in diameter and characterised by great robustness of growth. This fine Violet was, we think, placed in commerce by Mr. Charles Turner of Slough.]

— **PYRETHRUM ULIGINOSUM.**—This is always appreciated, but never in my recollection has it been of greater service than at the present time. A showery season just suits it, and the numerous growths in each strong clump are much taller than usual. All are branching and flowering grandly, and are quite uninjured by frosts, whereas nearly all other plants in the mixed borders are completely spoilt. Harvest Thanksgivings generally have been rather late, and what the decorators would have done without a bountiful supply of these "Marguerites" it

is difficult to decide. For vases, again, they are most useful, the beautiful white flowers, borne on long wiry stems, exactly meeting the requirements of all who delight in light and tasteful arrangements. Plants ought to be found in the shrubberies and in the back rows of the herbaceous or mixed borders everywhere.—W. I.

— I HAVE noticed your various correspondents' remarks on the resting of *EUPHARIS GRANDIFLORA* as a means of flowering it successfully. Many cultivators, no doubt, have tried the resting. Some have tried it to their cost, others to their profit. Still resting, to be of the right benefit, requires to be proceeded with cautiously. I could quote plenty of instances where taking the plants into cool houses had not the desired effect, when they flowered equally well with never having been taken out of the stove, only being kept dry there. During June and July I would not hesitate much to put *Eucharises* outside to rest in a sheltered and suitable place, but at any other time, cool houses, I think, would be risky, weakening the plants and bringing on diseases. There is apparently no accounting for how they do so well at times and at other times so poorly. I have just been pleased to count seventeen spikes of flowers coming up on a plant now; and the same had over fifty spikes of flowers on it when we exhibited it last August, since which time it has not been out of the stove.—R. M.

ROYAL PATRONAGE OF THE ROSE.

WE understand that H.R.H. the Princess of Wales has kindly consented to become the Patroness of the National Rose Society.

THE MANETTI STOCK.

MR. B. R. CANT'S communication on page 342 is very interesting, and in the face of what he says I suppose I must admit that Roses will do on the Manetti, at any rate in some favoured neighbourhoods. Messrs. Baker and Jowitt I think both reside in very genial climates, as does Mr. Cant himself. In such situations the Manetti may answer, but how many of us can reside in places with a climate like Hereford or Colchester? I think the secret of Messrs. Jowitt and Baker's success, extending over several years, was owing more to the fact of their going in for big battalions more than anything else, and I have a shrewd suspicion that had they grown their Roses on the Briar, own root, or any other stock the result would have been the same. Mr. Cant says (page 343): "For choice I prefer the Briar cutting to . . . any other stock," so I suppose I may fairly conclude that if he were a small amateur about to plant a few dozens of Rose trees he would not go in for the Manetti even at Colchester. If Mr. Cant has four acres of cutbacks, I think he is the exception that proves the rule, and his statement surprises me very much. Mr. Cant objects to my printing his opinion of the Briar without putting in his remarks about the Manetti. I gave the authority chapter and verse, and his statement, "the Briar cutting is my especial favourite" was so straight, that I did not feel called upon to insert anything further. It was open to any reader to procure the "Rosarians' Year Book" and read the whole article. It is quite sufficient for me to know that Mr. Cant's favourite stock is the Briar; so it is mine, and so it is that of a good many others, and their number is growing larger every day. I should very much like somebody to come to Sheffield and plant a six-acre field with Roses on the Manetti, the result would be such a triumph for the Briar men. In conclusion, all I can say is that my opinion of the Manetti has been gained from hard-bought experience only, and my fertile imagination has not been in any way exercised for facts. For the first few years of my Rose-growing life I used Manetti only, and the result was so disheartening, and the loss so great, that I was very nearly at one time giving the whole thing up in despair. Then I tried the Briar. The losses ceased, and now I would be sorry indeed to have to do without my Roses—but no more Manetti, please.—D. GILMOUR, JUN.

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE anniversary dinner of the above named Society was held in the Cannon Street Hotel on Thursday evening, October 11th, Dr. Robert Hogg presiding, and H. J. Veitch, Esq., in the vice-chair. There was a large attendance of members and visitors, over one hundred being present, the Chairman being supported by Mr. John Laing, Mr. G. Paul, Mr. N. Sherwood, Mr. H. Herbst, Mr. G. Deal, Mr. Nutting, Mr. W. Collins (Secretary), and others. The chair was taken at 5.30 P.M., and after an excellent dinner had been disposed of, a long and interesting programme of toasts and songs was proceeded with, the latter portion of the entertainment being admirably rendered by Miss Mary Belval and friends.

The customary loyal toasts were duly honoured, and Dr. Hogg then proposed the toast of the evening, "Continued Success to the United Horticultural Benefit and Provident Society." He said that twenty-two years ago a society existed called the United Horticultural Society, which was composed of men of action and energy. They conceived the idea of holding an exhibition in the City of London, and the first was accordingly held in the Finsbury Square, another was held somewhere else, but the climax was that held in the Guildhall, which proved a great success. A number of gentlemen guaranteed £100 as the prize fund, and the results were so satisfactory that a considerable sum was left to the credit of the promoters. Although that society has disappeared it left behind it a bantling, and the profits of the above named shows formed the nucleus of the present fund. The Society is now flourishing, but not so well known as it should be, and he was glad to see the Committee had decided to come out into broad daylight. For many years they carried on their work with great caution, at one time nearly giving up in despair, but the tide turned, and they are now going on in a most satisfactory way.

The details of the several rules were very intricate, but he had endeavoured to master them, and would give a few particulars of the way the Society is worked. The objects of this Society are to render assistance to gardeners in time of sickness, calamity, and old age. It is not a charity, it is not even a benevolent society subsisting on the benevolence of others, but it is essentially a thrift and self-help society. It is in fact a benefit society and savings' bank combined, the payments not being more than those of the ordinary benefit societies whose members have no claim or surplus funds. There is, I believe, no other society which offers the same advantages. The overplus in this society is equitably divided amongst the members yearly, and invested for them in stock; each member has a separate account, and the accumulated fund, with all interest accruing, is payable on the death of a member to his nominee, or can be drawn by himself at the age of seventy years. Sums amounting to between £50 and upwards are now credited to some members, and the yearly interest on the same closely approaches the annual payments to the Society. This is a point of the greatest importance, for it means that in the course of time nearly, or quite, all the sums paid as contributions will be added to the members' deposit account, the interest meeting all liabilities that entitle such members to all the benefits of the Society.

The organisation consists of three funds—the benefit or sick fund, the management fund, and the benevolent fund. The benefit or sick fund is to provide a weekly payment to members when they are incapacitated from work through illness. When a member is wholly unable by sickness to follow his employment he is entitled to full sick pay; but it is not necessary that he refrain from all work when able to do a little, to entitle him to a proportion of sick pay. The management fund is to meet what may be called current expenses, such as rent, stationery, printing, &c. I would like to call special attention to this fund. The Committee, of course, as in other societies, give their services gratuitously; but the Secretary, on whom the heavy work devolves, has hitherto only received a nominal sum, and the most he is entitled to receive is £20 annually, with 6d. per annum for every member over 300. The benevolent fund is established to enable the Committee to grant extra allowances beyond sick pay where additional assistance is needed, as, for instance, to meet heavy doctors' bills, accidents, and sudden unforeseen calamities.

The payment of 6d. a week, or 26s. a year, insures 10s. 6d. weekly in case of sickness; 9d. weekly, or 36s. a year, insuring 16s. weekly. Members contributing 26s. yearly to the sick fund pay 2s. annually to the benevolent fund; those paying 39s. yearly contributing 3s. annually to the above fund; and all pay 2s. 6d. annually to the management fund. These are the whole of the liabilities; and I may state, as showing the very light nature generally of the demands on members, that the payments to sick members during the present financial year have amounted to £30 11s. 8d., this being met by deducting only 2s. 6d. from those members who contribute 26s. a year, thus leaving £1 3s. 6d. of their subscription to be added to their deposit account. After attaining seventy years of age the member ceases to pay into the sick fund at all, and he is provided for from the benevolent fund. The Society has been established twenty-two years, and the sum of £4200 is invested in consols, and is the property of the members, each member's share being debited to him in a separate account. There could be no question respecting the advantages of such a Society, and he had great pleasure in proposing its continued success. (Cheers.)

In replying, Mr. N. Cole briefly traced the progress of the Society, and referred to the valuable assistance Mr. J. Wright had rendered in making it so widely known, which had led to a large increase in the number of members.

"Success to Kindred Societies" was proposed by Mr. H. J. Veitch, who remarked that he was not prepared to furnish the meeting with such important statistics as the Chairman had done, but he could say that he was sure the kindred societies might and ought to help one another. As an example he stated that within a few months of the death of Mr. McElroy, the late Secretary of the United Horticultural Benefit Society, the Committee of the Gardeners' Royal Benevolent Institution was able to place the widow on the funds as a pensioner. Respecting the Gardeners' Orphan Fund, Mr. G. Deal would be able to give them more particulars than he could do, and in the unavoidable absence of Mr. John Lee he called upon the veteran Secretary, Mr. Cutler, and Mr. G. Deal to respond for the two societies mentioned. Mr. Cutler regretted that he had been named to reply, and he would have preferred

seeing their venerable friend, Mr. J. Lee, present to perform that task. The Gardeners' Royal Benevolent Institution is endeavouring to accomplish much good, and they had been very successful. As an indication of the importance of having a good balance, he mentioned that many years ago he had an interview of the late Baron Rothschild, and obtained from him a donation of £50 for the funds of the institution. The Baron asked what would be done with the money, and the reply was that they intended making it a nest egg, a course which was highly approved by the donor. In returning thanks for the Gardeners' Orphan Fund, Mr. G. Deal said that there were over 6000 kindred societies in London, with more than a million contributors, but they had much reason to be gratified with the progress of the fund in which he was specially interested, for though it had only been established a year, they had obtained between £1700 and £1800, and placed ten children on the fund. He congratulated the United Horticultural Benefit and Provident Society upon their satisfactory condition. It has been said that every benefit society is solvent that had an average of £6 per member in hand, but this Society has about £12 per member, and he attributed the result to some extent to the different funds for special purposes.

The "Honorary Members" was proposed by Mr. Hudson (the Treasurer), coupled with the named of Mr. J. Laing and Mr. W. Paul. He said they received material help from their hon. members, and they hoped to increase their numbers considerably. Mr. Laing had much pleasure in supporting the Society as well as the two other institutions specially for gardeners. Mr. Paul added his acknowledgments to those of Mr. Laing, and said that when he first saw one of the Society's circulars he was much struck with the unpretentious character and the indication of quiet determination to carry out their object. He hoped there is a future before the Society that would surpass the expectations of its most sanguine friends.

The "Health of the Chairman" was proposed by Mr. N. Sherwood, who said the thanks of the Society were due to Dr. Hogg for his assistance in presiding at the dinner, and for the encouraging remarks he had made. The Society is undoubtedly in a flourishing condition, but it deserves all support, and he was sure all would join in cordially wishing Dr. Hogg long life and health. This was performed most enthusiastically with musical honours. In responding, the Chairman observed that his sympathies were always with gardeners and gardening. For fifty-two years he had been closely associated with the horticulture of the metropolis, and though the winter frosts had come upon him and some of his fellow-workers, he hoped they would be spared to help for some time to come.

The next toast was, "The Trustees, Committee, and other Officers of the Society," and in proposing this Mr. J. Wright said—

The United Horticultural Benefit and Provident Society was started by gardeners for gardeners, and its directorate consists wholly of gardeners—the Trustees, Messrs. G. & J. Wheeler and J. George; Treasurer, Mr. J. Hudson; and Secretary, Mr. W. Collins, all being well-to-do members of the craft, men of high character, shrewd, practical, business men, who have steered a safe course, which is all-important. The Committee might, and no doubt would, have gone ahead faster but for the stringency of the rules leaving them practically without an administrative fund. The fundamental difference between this and ordinary benefit societies was forcibly stated to him a few years since by Mr. George Baker, late gardener at Coombe Cottage, Kingston-on-Thames, and now of Membrand Hall, Ivybridge, Devon, to whom the Society is much indebted for its success, and who was its Treasurer for many years. "I have paid," observed Mr. Baker, 7d. a week into the Old Fellows (or Foresters, I forget which), since I was eighteen years of age, and I am now fifty. I had, fortunately, had nothing out in that time, and if I go on paying all my life there will be £12 at my death." And then he continued—"I have paid 1d. a week less into our Gardeners' Society for seventeen years, and now have nearly £40 to my credit, and if I continue paying as long as I paid into the other I shall have £100. This is £100 if alive at seventy, against £12 at death, and 1d. a week paid more for the latter privilege than the former!"

Mr. Wright said it was in the year 1883 that he made himself intimately acquainted with this institution. He called on the Secretary and asked to examine the books. They were promptly placed before him, and he was invited to examine every page, scrutinise every item, and point out any fault. He could find no fault, and had great pleasure in placing the advantages the Institution offered to gardeners before the world. He intended to support in every way he could this and other kindred institutions established for the benefit of gardeners, their widows, and children.

Mr. J. Wheeler (Trustee) and Mr. Chard (Committee) replied briefly, and Mr. W. Collins (Secretary) remarked that there was little left for him to say respecting the Society, but he had one or two pleasant announcements to make. In the first place, before the proceedings commenced Dr. Hogg had handed him a cheque for £10; secondly, Mr. N. Sherwood had signified his intention of becoming a life member. They have now 270 benefit members and thirty honorary members, the numbers steadily increasing. He mentioned several cases in which their funds had been employed with considerable advantage to the members or their nominees, and he added that at the present time they have no sick members on their list.

The Chairman said it afforded him peculiar pleasure to propose the health of Mr. H. J. Veitch, their Vice-Chairman, for he had known him all his life, and known only good of him. He had also known Mr. Veitch's father, grandfather, and other members of his family, so that he had watched his progress with considerable interest. He also

referred in commendatory terms to the energy and ability with which Mr. H. J. Veitch, and his brother, Mr. John Veitch, entered on the management of the business at the death of their father. Mr. Veitch expressed his hearty thanks for the manner in which the Chairman had proposed his health, and he was glad to have an opportunity of publicly expressing his gratitude for the kindness and serviceable advice he had received from Dr. Hogg during many years of friendship. Mr. Veitch also proposed the next toast, the health of the visitors, coupled with the name of Mr. Baker, who responded briefly in suitable terms.

Mr. W. Paul proposed the "Horticultural Press," which was replied to by Mr. B. Wynne. Mr. Nutting moved that the best thanks of the meeting be given to Messrs. Williams, Laing, Cannell, Chard, and Thomson, who had contributed so liberally to the beautiful array of flowers and fruit provided, and the proposition was carried with acclamation. The Chairman then tendered the thanks of the meeting to Miss Mary Belval and her musical friends for their excellent contribution to the pleasure of the evening, and the proceedings terminated shortly before 10 P.M., all being thoroughly satisfied with this most agreeable gathering.

FRUIT-NAME HOLDER.

It is quite common to see the names of fruits laid on the plates at exhibitions, and they are apt to get misplaced in being taken up by

FIG. 42.—FRUIT-NAME HOLDER.

visitors and put back on the wrong dishes. The holder figured we brought from the Chiswick Fruit Conference. It is made of a piece of wire, the size of a stout knitting needle, and about 30 inches long. One end is made into a circle nearly 5 inches in diameter and looped, the other bent over to the centre of the circle, then taken upright, and at the height of 6 inches given a twist and formed into a square or nearly so, the end finishing with a hook as shown. A label can be suspended from the hook, or a card with name placed behind it, where it is held firm by the spring of the wire. One side of the circular base placed under the plate brings the name above the fruit at the back of the dish, and the little contrivance answers its purpose well. It is an American or Canadian idea, and a number of the holders fell into the hands of Mr. Barron at the Colonial Exhibition. Any handy man can make them. Other forms of holders equally simple can be affixed to the plates.

KITCHEN GARDEN.

ASPARAGUS PLANTATIONS.—Asparagus plants have grown very well this season. They are much more luxuriant than last year, but the growths are much greener than they were in mid-October, 1887. The roots and crowns are less matured too, and probably they may not be in such good order for early forcing as we desire, but they will improve considerably in this respect. If the surface of the bed is covered with weeds remove them at once, as they will hinder the crowns from maturing. Should any kind of vegetable crops have been growing between the Asparagus, these should also be removed, but do not cut away any of the Asparagus stems until they have withered. The inexperienced are very apt to "trim" the growths as soon as they begin to appear brown, but this is a mistake that must be guarded against, and the seasonable work that applies to all Asparagus at the present time is clean the surface of the beds and leave the tops alone. As an indication of the unfavourable summer our Asparagus has failed to berry this year.

RHUBARB FOR EARLY FORCING.—As Apples are scarce in many parts substitutes will have to be found for them, and none is more readily secured than Rhubarb. Good roots are easily forced to secure a supply in December, and as most garden owners have always plenty of roots they ought to be taken advantage of. Roots that have been grown for some years in the same place are much better for forcing than those that have been divided or transplanted last year or the year before, and very large sorts are not so suitable for forcing as the smaller varieties. Probably the whole of the roots in a quarter would not be ready for forcing, but it may be necessary to select one here and there, and those with very prominent crowns should be chosen. Do not disturb them now, but as the leaves die remove them at once and expose the crowns as much as possible to the sun.

EARTHING SPRING CABBAGES.—The spring Cabbage have grown freely of late. Many of them are ready for earthing up now, and they are much benefited by this practice, as it protects their stems in winter and keeps them firm in the ground, two important points in the successful wintering of all open-air plants. Should there be any blanks fill them up before beginning to earth, and draw the soil well up to their necks.

STORING BEETROOT.—Beetroot is the least hardy of all vegetable roots, and it should be taken up and protected before frost injures it. If the roots are firm and deep in the soil loose them with a fork, but do not break them, as this would allow the ice to escape. Very large roots must be rejected. Those of Dell's type are the best. The leaves should not be cut close into the crown, but about 3 inches from it, as if cut in the roots will bleed, and this takes away the virtues. They must be stored under cover, where wet and frost will not reach them, but they must also be kept cool to prevent their growing again. Moderately dry leaf soil, ashes, or sand are the materials in which they may be stored, and if they are placed in a heap so as to have all the crowns projecting outwards they will keep well.

LATE TOMATOES.—Late fruits may be secured from plants that have been growing all the summer under glass. We have lately cut all the ripe fruits from them, removed every dead leaf and superfluous shoot, and given them a little rich surface dressing. There are many late green fruit on them still, and this will cause these to swell and ripen until well into winter. Although the plants may be leafless near the bottom of the stems this will not prevent the top fruit from succeeding, and as Tomatoes at Christmas are very valuable the utmost attention should be given to old plants now. In many cases they will have been grown all the summer without fire heat, but this should now be applied to assist them.

KIDNEY BEAN SEED.—In some seasons we have gathered much of this, but our crop is very backward this year; indeed it was never more so, and we would not advise anyone to save and trust to half-ripened seed. The dwarf varieties have become quite ripe, but it is the runners that have failed, and unless the pods have become quite brown and the seed firm do not save it.

VEGETABLE MARROWS.—The frost has cut down the leaves, and many half-sized fruits have come to light. If these are left on the ground they will soon decay, but if cut and placed in a dry room they will remain sound and good for many weeks.

FRUIT FORCING.

VINES.—With so many good varieties of late Grapes that we now possess early forcing is not by any means essential for a supply of Grapes all the year round. The most valuable late-keeping Grape is Lady Downe's; it bears well, and the fruit keeps fresh and plump up to June. In quality it is unsurpassed, for when ripened in strong heat the Muscat flavour is more highly developed than in a low temperature. This is well, as all late-keeping Grapes owe much of those properties to thorough ripening under the influence of sun and strong heat; in fact, Grapes that are to hang for any length of time must not be ripened in cool vineries. Black Hamburgs, for instance, will not remain in

good condition nearly so well if ripened in a cool house as when the fruit is perfected by fire heat, whilst Muscat of Alexandria speedily becomes spotted when not ripened to an amber colour. Alicante is an excellent keeper and always finishes well. West's St. Peter's also finishes well in a high temperature, and though not so imposing in appearance as some others, it is one of the best late Grapes. Gros Colman is simply magnificent in appearance, the berries 4 or more inches in circumference, the bunches about 4 lbs. in weight, and when well ripened it is not nearly so coarse and inferior in flavour as it is sometimes represented to be. It requires, however, a longer time to colour and ripen than the majority of late Grapes.

Gros Guillaume is really unsurpassed in imposing appearance, the bunches being large and the berries approaching Gros Colman in size, and when well ripened and coloured the quality is good. Golden Grapes are not at all to the fore as the black. Pearson's Golden Queen and Mrs. Pearson are good additions to this class of Grapes, and are more easily kept than Muscat of Alexandria but those can hardly be kept over the new year, therefore we have nothing better to offer than Trebbiano and Calabrian Raisin, with Syrian, as good companions to the thick-skinned black Grapes. They are large in bunch and berry, and when well ripened excellent in quality and good keepers. When well ripened to the shank, Mrs. Pince is one of the best of the thick-skinned varieties, with a decided Muscat flavour. With these varieties to maintain the supply up to May, the necessity of starting permanently planted Vines before December does not arise unless it is desired to have fresh ripe at an early date in spring. In that case it is preferable to take the early supply from Vines in pots than to start the permanently planted Vines so early. Vines in pots produce fruit but little inferior to that borne by those planted out, and often better, from the roots being inside, and where there is means of affording bottom heat success is certain, providing, of course, the canes are sufficiently strong and well ripened.

Early Forced Vines in Pots, &c.—Where leaves and stable litter have been prepared as advised in our last calendar, they should be placed on outside borders, and a quantity of the material introduced at that time to the interior of the house, which will produce a regular degree of heat and moisture without having to resort so much to fire heat and frequent sprinklings. Vines in pots plunged in bottom heat must not have a greater heat than 65° to 70° to begin with, augmenting it by bringing up the fermenting materials to the level of the pots, so as to raise it to 70° or 75° when the Vines are in leaf. Both Vines in pots and early forced Vines have ripened so late that, except under pressing circumstances, it will be sound practice to defer starting to as late a period as possible. Young Vines that have completed their growth should have a portion of the laterals cut off to admit light and air to the principal leaves and buds, thereby inducing earlier ripening of both wood and buds.

CUCUMBERS.—Place out at once the plants for fruiting in winter on hillock or ridges as near to the glass as the nature of the house and trellis will permit. Those not having the convenience of a house may obtain supplies of fruit by growing the plants in pots or boxes in Pine stoves or other sufficiently heated structures. Let the autumn-fruiting plants be regularly looked over once a week, removing any bad leaves and exhausted growths, training in young growth, pinching out the point of the shoots a joint or two beyond the fruit, avoiding overcropping and overcrowding, and removing male blossoms. Keep the temperature at 70° at night and 75° by day, advancing with 80° or 85° with sun heat, admitting a little air whenever the external air is favourable. Keep the glass clean, as every ray of light is now of consequence. Moderate the supply of water at the roots, not, however, permitting flagging.

MELONS.—The Melon season as regards dung-heated pits and frames may now be considered at an end. Any fruits yet remaining and fully grown may be cut and placed in a warm house to ripen. The latest plants in houses will require a night temperature of 70° to 75° by day by artificial means, advancing to 85° with sun heat, admitting a little air at every favourable opportunity. Sprinkling the paths, &c., will be necessary about 8 A.M. and 3 P.M. until the fruit is full grown, when a drier atmosphere will be advisable. Cut out all superfluous laterals, well thinning the old foliage, so that the fruit may have the full benefit of the autumn sun. Before the ground is soaked by rains secure the required quantity of compost for next year's crop—rather strong loam taken off with its turf, stacking grass side downwards, adding about a bushel of quicklime to each cartload in stacking it. It will be in capital condition by spring.

PINES.—All young plants should now be arranged so as to obtain the fullest benefit of light and air. As the sun heat diminishes a corresponding diminution of temperature should take place at night until it reaches the winter standard of 55° to 60° at night and 65° in the daytime. Ventilate freely whenever outside conditions are favourable, paying particular attention to watering. An inspection of the plants should be made about once a week, and whenever a plant needs water supply it copiously at about the temperature of the bed. Plants on which fruit is now appearing will be ripe at a time when other fruits are scarce, and should therefore be afforded a good position in the fruiting house. Continue 70° as the minimum temperature in the fruiting house, though on cold nights a decline of 5° may be allowed, and 5° more in mild weather—75° artificially by day and 80° to 90° from sun, closing the house at 80°, sprinkling as may be necessary the pathways when they become dry, and on sunny afternoons an occasional syringing will be advantageous, keeping the bottom heat regular at 85° to 90°.

PLANT HOUSES.

Primulas.—In moderately dry localities these plants may be safely left for a few weeks longer in cold frames, but in others it will be necessary to place them in light airy structures to insure their safety from damp. All, with the exception of those provided for spring flowering, should be placed in their largest pots and be grown close to the glass where plenty of air can be admitted to insure dwarf sturdy growth. The latest plants, if they are not in 3-inch pots, should be placed in them without delay. Water all carefully from the present time, and avoid extremes, for no condition will induce them to damp sooner than being first wet and then dry. Try to keep them as nearly as possible in an intermediate state for moisture. Soot water in a clear state will prove very beneficial to those now coming into flower. It is a good plan to top-dress these, especially if they are loose at the collar. They soon emit roots, and thus secure themselves to a large extent against damp.

Cinerarias.—Frame-room will now be plentiful, and these must be potted from time to time as they need more root-room. Give the plants plenty of room to develop themselves. If they are crowded, moisture will hang about them and cause them to damp. In the morning the plants will frequently be covered with dew, and the frames must be liberally ventilated so that this can be evaporated early in the day. No harm will result to the plants as long as this can be removed daily, but if allowed to hang about the plants several days in succession they will commence damping. With care, however, this can be avoided for some weeks to come. What watering is necessary should be done in the morning. The earliest plants that are required in flower as early as possible may be placed in a light airy structure. Weak stimulants may be given every time they need water. Stand them on moisture-holding material, for a dry base means destruction in a very short time to their lower foliage. Watch for aphides, and destroy them by light fumigations with tobacco directly they make their appearance.

Roman Hyacinths and Narcissus.—The earliest will be ready for removal from the plunging material. These should, if practicable, be placed in frames where they can be covered with a mat until their foliage naturally turns green. The object is to expose them gradually to the light, and if this is done no injury to their foliage will result. They will need liberal supplies of water from the present time.

Lily of the Valley.—As these come to hand it must be decided according to the quantity required at one time whether they are to be placed in pots, pans, or boxes. Our earliest spikes are obtained from single crowns plunged amongst cocoa-nut fibre refuse just as they are received. Before introducing them into heat, however, lay them in ashes outside until they have been exposed to one or more sharp frosts. They force all the quicker and easier by this seeming delay at the start. Clumps should be placed into 5-inch pots and all may be stood outside or plunged, leaving the crowns exposed.

Spiræas.—Early frosts have completed the growth of these plants, and they can be lifted and potted as opportunity offers. Plants with small weak crowns may be divided and planted for forcing purposes another year. On the whole the crowns are not so ripe as they have been for several years, and we have doubts whether they will flower as freely as they have done for several years past. Place them outside after they are potted, and to be on the safe side pot up a good number of imported clumps.

Dielytra spectabilis.—Lift these and place the best crowns into 5-inch pots, the small ones being reserved for planting again. These after potting can be placed in cold frames or may be placed outside where slight protection to their crowns can be given in case of sharp frosts.

Viburnum Opulus.—Lift year-old plants from outside and place them in pots so that they will make a few roots before the foliage falls. Plunge the pots in a sunny position outside where they can remain the whole of the summer. When lifted early and placed in 5 and 6-inch pots they start away freely in spring and make splendid plants for forcing by the following autumn. Deutzias may be lifted, but these should be wintered and started into growth in cold frames. For the present place them outside and syringe freely on all drying occasions to keep their foliage fresh as long as possible.

THE BEE-KEEPER.

FINAL PREPARATIONS FOR WINTER.

IN many apiaries weeds and rank grass are allowed to luxuriate. This is both careless and unprofitable. The lives of many bees will be saved if in the immediate neighbourhood of the hives the herbage is kept short and close, but still greater is the benefit when a bare space covered with cinders can be given in the immediate front and at the sides of each stock. The method of arrangement of the stocks should be systematic without being uniform. On no account should hives be placed in a straight line. Some may be set back a few paces, and some may be brought forward, or these may even be placed with advantage, under certain circumstances, in

a quincunx. Those hives which rest on wooden supports should at once undergo a very careful examination, and the sooner any defects are remedied the better. It is possible that some hives may be cracked owing to the contraction of the wood or to imperfect construction, and it is most important that all such "damp traps" should at once be filled up and receive a good coat of thick paint. In this way much danger and loss may be averted with very little trouble. All surplus cases must be removed, but on no account should the body box be contracted. All store should be sealed, and the inside of every hive ought to be clean and dry. Warm coverings may at once be brought into use, and every stock must at once be placed in a position to withstand the coming winter without the necessity for any further and later, and consequently objectionable, manipulation.

Everything that can be done for the benefit of the stocks should be done, and that without delay while the weather is fine, warm, and suitable. A box of cork dust or chaff placed upon one thickness of felt and a piece of ticking is a very excellent winter covering, and one which can hardly be improved upon. Care must be taken to trap any mice which are known to be in the vicinity of the stocks, and all boards or bricks which may assist these animals in gaining an entrance to the stocks must be removed to a position in which they can be of no such use to these bee enemies. An apiary littered with boxes, supers, boards, bricks, and other remnants looks untidy and betrays the character of the bee-keeper. Neatness may not be a necessary adjunct to success, but where we find a neat and orderly arrangement of the apiary and its belongings, we expect with certainty to hear of success in the conduct of the industry.

Most bee-keepers, and especially those who have all to learn, may, during the winter months, study with advantage the theory of bee-keeping, and they can hardly employ their spare time more usefully than in the study of a standard work upon the subject, and we would especially commend to those who require a complete theoretical knowledge, Mr. Cheshire's "Becs and Bee-keeping," and Mr. Webster's latest work on the subject. These books are very exhaustive, and are written with painstaking care, and can hardly be surpassed, but it is hardly necessary to remind the bee-keeper that even after having carefully studied such works as these he is very far removed from being a practical bee-keeper. Theoretical knowledge is the basis of practical success, but practical success does not necessarily follow from a knowledge of the theory.

There is one lesson which many bee-keepers who have to learn upon others for support cannot too well remember, and that is the necessity for following out the instructions given them even down to the minutest detail. When a bee-keeper gives one who has less knowledge than himself instructions he does so, generally speaking, in a clear and concise manner, and provided those details are closely followed out success is practically assured. But the person who seeks instruction too often thinks that such and such a thing may be omitted. Acting upon such ideas he carries out his instructions in a half-hearted sort of manner and then complains of failure. No doubt many bee-keepers fail to carry out the instructions of those who know more than themselves, because they are unable to see the utility of some parts of these instructions, and that is one reason why we, at the risk of repeating ourselves, always endeavour to give a reason for every instruction we give; but such reasons cannot be given in every case, because if such reasons were so given our articles would assume such vast proportions that the Editor would either at once condemn them to the waste paper basket or, at any rate, prune them to a reasonable extent. A reflecting man with a knowledge of the theory of bee-keeping can often supply a reason for a certain instruction, and a man who is not endowed with a capacity for reflection, or who has not a sufficient knowledge of the theory, has only to follow the instructions he receives in their entirety, as he is hardly likely, in his state of ignorance, to improve upon them, and is almost certain in his presumption to bring about a disastrous

result. Children must first creep, then walk, and afterwards run. A novice in bee-keeping is in exactly the same position, and if he tries to run while he is hardly able to creep the fall of that novice will be great, and his lamentation exceedingly loud. He has only himself to blame and must bear the loss, consoling himself by the knowledge that he will learn by experience. We do not desire to discourage the ardent bee-keeper, but only to warn him not to rush headlong into trouble. When he has a little experience, and begins to feel his legs, then he may begin to play antics and perform those feats which men who have the full use of their limbs are able to accomplish; but in the beginning his pace must be slow and sure, and though he may think the way somewhat long and weary, he will discover that the shorter road is often the longest to him who does not know the country over which he has to pass.—FELIX.

NOTES ON BEES.

AT THE HEATHER.

SINCE the discussion last year as to how far bees should be placed from or near to the Heather I have been experimenting and taking evidence on the subject. Bees placed a quarter of a mile from it gathered 6 lbs. more than those did a mile further away. One hundred hives standing right in the Heather at the bend of what may be termed a right angle of miles of Heather both ways, but had to fly for the superior Heather a mile, made from 10 to 15 lbs. less than about the same number placed one mile nearer. The greatest gathering of honey was made by crossed Cyprians and Syrians of my own stocks, so much in advance of others as to give surplus in this very unfavourable year for bees, thus maintaining their previous good honey gathering qualities, which is so pronounced as to enable me to dispense with feeding for a period of nearly twelve years now since I first had Cyprians. The greatest feat, however, of any onespring stock was a Carniolian I presented in November last to an old bee-keeper of more than fifty years for gratuitous and voluntary services in assisting me with my bees and garden. Previous to that date I gave him what I thought a choice Syrian queen, but it had swarmed at the Heather, and the queen regnant was a drone breeder. To make good that loss I gave him a choice Carniolian; it swarmed twice, and the gross weights of the three at the beginning of October were—old stock 80 lbs., first swarm 119 lbs., second swarms 52 lbs., total 251 lbs. The tare of these hives is 60 lbs. The first swarm kept itself from the beginning of August until the beginning of October, replaced brood with honey, and added 50 lbs. to the good. The old stock and second swarm did the same, but added about 15 lbs. less than the prime swarm. The second swarm, however, filled a super of beautiful Heather comb—the only one worth speaking of in the locality. The bees placed furthest from the Heather have lost many bees, while those near it have maintained their number.

I have considerable more evidence which might be produced, but think the foregoing sufficient to establish the fact that the nearer the bees are placed to the working ground the better, and that foreign varieties of bees far outstrip the native bee in the production of honey. I had only one native hive of bees strong, strong, too, in numbers, and it did not make an ounce. Although one hive is not sufficient as a test, still it is ominous, and fully corroborates our past experience.

TRANSPOSING SUPERS.

I am still more convinced than ever that it is a mistake to place an empty between the stock hive and full one. In every case of the kind I have witnessed this year the full super was emptied. Moreover, it is unnatural for bees to work in the manner indicated. They never separate themselves to build combs, but maintain an unbroken cluster.

COMBINATION HIVE.

It may perhaps interest your readers, and particularly "A Hallamshire Bee-keeper," to learn that all the greatest weights have been made by bees in the "storifying" hives. Those in small hives of the "Standard" pattern have done nothing, so we north of the Tweed have made a score this year in that respect. Three hives of the Lanarkshire type, and three of Abbott's "Combination" type, the property of a gentleman at Lanark, were intended for a fair trial. The Lanarkshire ones had pushed ahead of the Combination ones during June and July, but there was no competition at the Heather, as the three Combination hives were smothered, and their contents wrought into a jelly on the way to the Heather. Here the words of their advocate, which were delivered before the B.B.K.A., "That the hive suitable for one locality was

not that for another," was fully verified. But side by side of them were hives suitable for any and every locality or country.

It is now more than thirty years since I made a hive on this principle, but differing widely from it, being made upon the bevel, rising behind about 9 or 10 inches, the frames being bevelled to suit the angle of the hive, in order to make it available for taking to and from the Heather. Two boxes about half the length of the other were made to receive the frames. The stand, too, as well as the supers, were all made to an angle. This hive presented some advantages over other forms, notably that of supering, as like "A Hallamshire Bee-keeper," I have long since known that bees stored their honey overhead, and in the warmest place, and not behind the frames, the coldest part of the hive.

PREPARING FOR WINTER.

It should be borne in mind that the less honey bees require to consume during the winter the more healthy will the colony be. The best way to secure this is to prepare now and never more disturb the bees until the spring is advanced. One manipulation at the wrong time is sufficient to insure the destruction of the best hive. On no pretext whatever should cold air be admitted to the hive from above, and the more cosy they are kept the better.

Meadow hay forms the best protection to hives both on the sides and the top; a piece of felt should cover the hay on sides and a watertight roof of some sort raised a little from the hay with ample ventilation at the eaves. This covering is perhaps not quite so neat-looking as wood, and loose hay never looks well in an otherwise well kept garden.

Outside eases are sometimes heavy to lift, and always occupy the same space whether tenanted or not. A good substitute, and much better in most respects, are four panels or shutters the full height of hive and two tiers or supers. Perhaps the cheapest and most simple plan of fastening these together is by brass screws, two in each side. The wood should not be more than half an inch for the uprights and three-eighths for the bars. That size is necessary to cover handles and fastenings.

This makes a neat and cheap cover which anyone can make, and is a thorough protection against wind and water. If desirable, the space between the bars may be filled with hay, or a piece of felt may be tacked on. Of course an entrance corresponding with entrance to hive must be left, and the roof may be from a sheet of iron or zinc to an expensive and as ornamental a roof as the bee-keeper may desire. This form of protection is the only one of double casing that prevents decay in hives.—A LANARKSHIRE BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

Frank Cant, Colchester.—*Catalogue of Roses.*

Paul & Sons, Old Nurseries, Cheshunt.—*Catalogues of Roses, Fruit and other Trees.*

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

To Inquirers.—Answers to several letters, some of which were late in arrival, must be deferred till next week.

Market Terms (R. C.).—A pad of Plums varies from 48 lbs. to 56 lbs. There are five dozen Cabbages in a tally, but the number of Onions in a bunch and the price vary considerably.

Chrysanthemums (D. B. C.).—During the next few weeks you will find ample information of the character required. From the middle of October to the end of December Chrysanthemum news, notes, and articles are most abundant.

Plum-shaped Tomato (G. H.).—The fruits you have sent are

attractive in a dish, and good in quality. The variety is either Nesbit's Victoria or a selection from it. These small Plum-shaped Tomatoes are included in the dessert of many families where other than sweet and luscious fruits are enjoyed.

Dessert Pears (*J. Truro*).—As you desire a list of varieties "according to the report of the Fruit Committee," you cannot, perhaps, do better than read the reports of the National Fruit Conference that is being held at Chiswick this week. There is no gardeners' benefit society in Liverpool. The address of the Secretary of the Liverpool Horticultural Association is Mr. E. Bridge, Tarboek Road, Huyton, Liverpool.

Lapageria Unhealthy (*G. H. C.*).—Are you sure the plant has had sufficient water? With free drainage it is not easy to give too much in the summer. A dry atmosphere and much sun are also unfavourable to free growth and fine leaves. Those sent lead us to think either the soil has not been kept moist enough, or the air kept too dry. We assume the compost is suitable, but this you do not indicate.

Mildew on Cinerarias (*W. A. M.*).—Leaves that are checked in growth like the small one sent, we should burn, but those only slightly affected we should endeavour to save, and we should not like to destroy the plants, at least at present. Try the effect of black sulphur, so holding the leaves that the points of the fine hairs face the application; the sulphur then may fall between them. It is the downy covering that we suspect prevents its reaching the mildew. We should also maintain a drier atmosphere if you can do so. The soil is perhaps fully too rich, and the leaves have not been able to elaborate the crude sap that has been abundantly afforded.

Sowing Orchid Seed (*M. N. S.*).—Experience has shown that there is no method equal to scattering the seed on the sphagnum in which a plant is growing freely and receives proper attention in watering, so that the sphagnum is kept fresh. No attempt must be made to cover the seed, and it must not be displaced by watering. The seed may be sown as soon as ripe, or in early spring. It is delicate work raising Orchids from seed, then establishing the plants, and only experts or very careful cultivators can hope to succeed. If you succeed in raising plants you must be prepared to give them the best attention for about ten years before they will flower. Some seedlings are fifteen years before flowers are produced, and then the varieties may not be superior, but, on the other hand, some may prove of value.

Araucaria Unhealthy (*W. Smith*).—We have seen many such instances as the one you bring to our notice, and in almost every case where injury has not been caused by frost the degeneration of the specimens has been due to soil exhaustion. The remedy is to remove the old soil down to the roots and beyond them, and if these are in a medium almost as dry as dust to apply pure water copiously, following a day or two afterwards with liquid manure. After the soil has been rendered sufficiently moist cover the roots with fresh compost, turfy loam, wood ashes, and decayed vegetable matter in equal parts, and surface the whole with manure. We have seen many specimens invigorated by this practice, and you cannot too soon apply the same remedy. In some cases the decay of the branches results from the roots having penetrated stagnant soil, and this case drainage must be afforded as well as top-dressing.

Trees and Shrubs for Chalk Banks (*W.*).—Of all trees the most likely to succeed is the Beech (*Fagus sylvatica*), which we should use chiefly along with others of the same genus—viz., Fern-leaved and Purple-leaved. Birch, as you have found, does fairly. The Hazel, Privet, and Blackthorn will afford the "cover" required. Bird Cherry (*Cerasus Padus*), and the Virginian form (*C. Padus virginiana*), Scotch Laburnum, Mountain Ash, Gold-variegated Elder (common Elder being desirable as shelter), Scarlet-fruited Elder, *Euonymus europæus*, Elms, Exeter and English White Beam, Lime, red-twigged and Snowy Mespilus may be added if you wish for greater variety. In evergreens, English Yew and common Holly, with *Mahonia aquifolia*, *Hypericum calycinum*, Broom, and common Laurel (in the lowest situations) may be used. Corsican and Austrian Pine would probably succeed, particularly the latter. Your second letter cannot be answered this week.

Marechal Niel Rose (*R. P.*).—You must keep the house in which your *Marechal Niel* Rose is growing as cool as possible until the end of December, so as to ripen the wood and bring the growth to a complete standstill. Early in January keep the house closer, say 45° to 50° at night, with a rise of 5° or 10° by day, by closing early in the day while the sun is upon it, and on fine days syringe the plant gently until it shows signs of bursting into growth. As soon as this stage is reached the temperature may be raised gradually 5° or 10° by night, as the young shoots that will bear the flowers lengthen out. Never should a higher temperature than 60° be maintained at night, and this only when very mild externally. Nothing is gained by a high temperature in forcing Roses into bloom, and it is much better to allow the temperature to fall to 50° by morning than keep it at the highest point given when the weather is very cold and frosty. Take every advantage of the sun to close the house early in the afternoon, for no harm will be done if the temperature increases, say to 80° or 85° for a few hours by sun heat alone. Be careful to avoid cold draughts striking directly upon the young tender foliage, for nothing will cause an attack of mildew sooner. You had better allow the temperature of the house to run up considerably than admit cold currents of air to the tender growths of your Rose tree. If you follow the directions given we do not think you will fail to have Rose blooms early in March.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. K.*)—The Plums having been placed without any packing in a half-filled tin box and nothing to keep them firm were shaken into a jam-like mass on arrival. (*G. Cooke*).—Your Grape is, we think, the Trebbiano, but note if the leaves are downy beneath. The fruit is well grown and ripened, and represents the variety in its best condition. (*T. P.*).—1, Like Beurré Diel. 2, Fondante d'Autonne. 3, Comte de Lamy. 4, Beurré Diel. 5, Comte de Flandre. 6, Swan's Egg. (*Dico*).—1, Van Mons Léon Leelere. 2, Marie Louise. 3, Louise Bonne of Jersey. 4, Souvenir du Congrès. The Apple, Cox's Pomona. The others not recognised. (*Dr. Lowther*).—1, Chaumontel. 5, Easter Beurré. (*G. G.*).—1, Cox's Golden Drop. 3, Cockle's Pippin. 4, Nonesuch. 5, Hoary Morning. (*Y. Z.*).—1, Beurré Hardy. 2, Knight's Pengethley. 3, Rivers' Monarch. 4, Yorkshire Greening. 5, Not known. 6, Braddick's Nonpareil. (*P. Le C.*).—1, Cellini. 2, Reinette du Canada. 3, Cox's Pomona. 4, Cox's Orange Pippin. 5, Dutch Mignonne. 6, Northern Greening. (*J. and W. Birch*).—A, Yorkshire Greening. B, Golden Spire.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*E. H.*).—The specimen was not a good one, but it resembles *Rudbeckia hirta*. (*J. S.*).—1, *Asplenium bulbiferum*. 2, *Adiantum Capillus-Veneris*. 3, Insufficient without spores. 4, *Pteris eretica*. 5, *Polypodium vulgare*. 6, *Adiantum euneatum*. (*W. R.*).—1, *Sibthorpia europæa*. Yes, there is a variegated form, but it is rather difficult to grow. 2, *Masdevallia Harryana*.

COVENT GARDEN MARKET.—OCTOBER 17TH.

IMPROVEMENT in the demand for Peaches, otherwise no alteration.

LIVE STOCK.

MICHAELMAS is the term in most districts when farms are taken in hand, and particular attention is given to the selection of animals suitable for the special purpose for which the farm is required. Under the comprehensive term of live stock, all animals kept thereon are included, and as frequent inquiries reach us as to which are the most suitable for the home farmer, we purpose calling special attention to the matter this week.

Before all things the home farm is intended to afford a full and constant supply of farm produce throughout the year for consumption at the hall, castle, or mansion, as the case may be. For such supply to be satisfactory, every article sent from the farm to the kitchen must be of the highest possible degree of excellence. To insure this, it is a matter of primary importance to make a careful selection of live stock. Jersey cows, Southdown sheep, Highland cattle, Berkshire or Tamworth pigs, black Norfolk Turkeys, pintail Ducks, Dorking chickens, geese, Guinea fowls and pigeons, are among the most desirable stock for the purpose, milk, cream, butter, beef, mutton, pork, hams, chops, bacon, lard, eggs, and poultry being always in demand; and we hope, as skill and knowledge in dairy management improves, that cheese will be added to the list, for there can be no good reason why really good cheese should not be forthcoming from home farms generally as well as good butter.

In the selection of cows we should certainly advise beginners to confine themselves to pure bred animals, either Jerseys, Guernseys, Ayrshires, or Kerries. All four breeds are excellent, and a novice can hardly go wrong among them, provided due care is taken in the selection of cows to form a herd. No doubt cross-bred cows, such as we have in Guernseys and Shorthorns, Jerseys and Ayrshires, Dutch and Redpolls, afford more useful animals, but such cross-breeding is only advisable in the hands of farmers of much experience. The reputation of Jerseys for richness of milk is so high that we cannot wonder at the general preference for cows of that breed, but it should never be forgotten that the Jersey is a delicate animal, requiring extra care in its food and shelter. The Guernsey is a more robust animal of larger frame, and its milk is very rich. We have found it altogether more useful than the Jersey, the dairy produce being equally valuable and generally more abundant, while the cows are invaluable for cross-breeding purposes. Both Ayrshires and Kerries are hardy races, and by the exercise of care in selection and breeding many valuable herds of them have been formed. The hardy little Kerries are our especial favourites, but we question if they are yet sufficiently plentiful in this country for really good cows to be obtained easily. The best way of laying the foundation of a herd of them is to purchase two or three cows and a bull of known excellence at one of the metropolitan dairy shows. The price for such choice animals is high, but it is much better and is really more economical to give it than to run the risk involved in the purchase of cheap imported animals of which not one in twenty may prove useful dairy cows.

Of pigs, special breeds may be indulged in for a fancy, but for all practical purposes a little care in selection from local breeds will suffice. Porkers of from 50 to 60 lbs. weight afford the best pork for roasting, pickling slightly, and for all other purposes for which fresh pork is required in the kitchen. For bacon and hams fat pigs of from 200 to 300 lbs. weight are required, and there must be enough of them brought on for killing and curing during the winter months to afford a supply of bacon and lard for the year. To insure a full supply and to meet emergencies there must always

be a moderate surplus over ordinary requirements, and there should be no difficulty in the disposal of such surplus if it is not required for home consumption.

In the management of poultry some of the chief points are to select fowls which have a full plump breast and legs of moderate size to afford nice chickens for table; to save plenty of poults from a few early successional broods to afford an autumn and winter supply of eggs; to have as many early broods of Turkeys as possible, late birds being notoriously delicate and unsatisfactory. Turkey poults should always be sufficiently forward to be ready for table by the end of September. Where poultry is reared regularly in considerable numbers there are often serious losses among the early broods from gapes. This may be avoided by keeping them on fresh land or on turf where chickens have not been reared before.

WORK ON THE HOME FARM.

With the sowing of Rye and Tares ended we can now turn in real earnest to Wheat-sowing where it can be done. But much of the heavy land ploughed for Wheat cannot be sown till the soil is softened by rain. We can wait for rain with a feeling of certainty that it will not be long in coming at this season of the year, and meanwhile sowing will be pushed on briskly on light land and mixed soil farms. We are much pleased with the appearance of the seed Salvator Wheat, which we have purchased at the fancy price of guinea a bushel. The grain is very large, it is white, and if only the yield does credit to the vendor's statement that it is 88 bushels an acre we shall have made a profitable investment. The weak point about this Wheat is the fact of the straw being very stout, and growing to a height of from 6 to 7 feet. In reality it is a kind of anomaly, for such stout straw is not likely to be laid by wind and rain; this is an advantage. On the other hand, very stout straw is frequently so coarse in texture that it is unfit for use for horses, at any rate for carriage horses, hunters, or race horses, and therefore it does not meet with the brisk sale of ordinary Wheat straw; this is a disadvantage. We send large quantities of straw to the Newmarket training stables, and cannot dispose of Rivett Wheat straw there.

So many Barley ears fell upon the stubbles in harvest that we have had to purchase fifty more store pigs for the home farm stubbles. We did not go to the open market for these pigs, but bought them of a tenant farmer, who had cleared his stubbles, and wanted to realise as much cash as he could for Michaelmas payments. We got fifty strong healthy animals at an average price of 15s. 6d. That price will answer very well indeed, for the pigs will find an abundance of food upon the stubbles for the next three weeks, and then they will be confined to a yard, and be fed with barleymeal ground from the damp and tail corn.

OUR LETTER BOX.

Wheat Manure (J. L.).—No farmyard manure is required with the artificial manure which is recommended on page 326. If you have farmyard manure it may be used for an autumn dressing now, and then a spring dressing of 1½ cwt. per acre of nitrate of soda will suffice without the addition of any of the other artificial manures enumerated.

REMARKS.

- 7th.—Fine autumn day.
8th.—Bright and pleasant throughout.
9th.—Bright morning, fine warm day.
10th.—Cloudy early; fine warm day.
11th.—Cloudy morning; bright afternoon and evening.
12th.—Fine and generally bright day; cloudy evening; showers at night.
13th.—Cloudless early, fine throughout.

An almost rainless week of lovely autumn weather. Temperature 4° above that of the preceding week, but still about 3° below the average.—G. J. SIMONS.

AN AWAKENING.

NO matter what may be said or thought on the lack of earnestness nowadays in the cause of horticulture as compared with the energy of its representatives in past times, the events of last week were quite sufficient to indicate that only opportunities are desired for showing that the old spirit of devotion to the work of cultivation has not departed, but is as active as ever. This was proved to demonstration. When we find cultivators at no small trouble, and not without expense to themselves, collecting and sending samples of fruit from various parts of the kingdom, and communicating information thereon of substantial value, without a thought of pecuniary recompense; but with the sole object of helping forward an important movement; when we find gentlemen come from two to four hundred miles to read papers, and specialists, wherever they may reside, giving their time and their talents in furtherance of fruit cultivation and distribution; when we find committees and censors rendering their services willingly and gratuitously, and without even expecting or receiving thanks for their endeavours; when we find gardeners and others assembling, if not "in their thousands," yet in such numbers as to form a great dense crowd, hanging on the utterances of the speakers, taking part in animating discussions, cheering good points and passing good resolutions; when we find all this, as we found it at Chiswick on the occasion of the Apple and Pear Conference, at least three important facts appear to stand out bold and clear. 1, That the horticultural spirit is very much alive and horticultural enterprise increasing. 2, That the Royal Horticultural Society has many friends—staunch, true, and willing to work for it and the objects for which it exists. 3, That Chiswick has not lost its charm on the horticultural community, but is an attracting power when used as a field of operations for the promotion of objects of scientific and practical value in accordance with the instincts of the gardening community.

The deductions that appear to be the not unnatural outcome of those facts are these—1, That earnestness in action in the fulfilment of definite objects of substantial horticultural value be encouraged. 2, That the Council of the Royal Horticultural Society make use of its friends, and not count them as enemies if their zeal in its interest impels them to move a step onward now and then beyond the prescribed lines. 3, That Chiswick be made, as far as it is possible to make it, the seat and the centre of scientific, practical, and experimental horticulture, on a broad basis for national purposes. Until action has been taken on those lines, and pursued earnestly and perseveringly, it cannot be known to what extent support will be rendered to the Society by the horticultural community. It may be said by the Council, as it was said by one of its members (Mr. Smee) at the close of the last meeting. We are quite willing, and even desirous, of developing the resources of Chiswick, but this can only be done by an increase of Fellows and funds. There has been an increase of Fellows, but Chiswick has, so far, not apparently benefited. There has been no surplus for that purpose. It is for the Council to consider if a reduction cannot be made in administrative charges, which would be tantamount to an increase of Fellows, and it can scarcely be doubted that more would follow as the result of a determination to make Chiswick the first object of consideration. At present work there cannot be done well and systematically.

No. 435.—VOL. XVII., THIRD SERIES.

There was no mistaking the desire of the Conference meetings, which were not composed of a body of mere sightseers, that a change should be instituted. So certain were some half dozen men who move among the multitude of gauging the feeling of the majority of those who are either Fellows of the Society or deeply interested in the work it ought to do, that no difficulty was felt in formulating resolutions expressing their wishes. One of these was passed with only four dissentients, and it is practically certain there would not have been one if it had not been put as an amendment to a motion of a restrictive nature dealing with railway charges for fruit. The passing of those resolutions was one of the most important results of the Conference, and as such they demand prominence, and are certain to receive the serious attention of the Council.

The resolution framed by Mr. Hibberd was not concerted, and as will be seen is of wide scope. It was seconded by Mr. J. Corner, and is as follows:—

"That a conspicuous result of the Conference this day concluded is to make it evident that the subject of commercial fruit culture is one of great and growing public interest, and that there exists a corresponding desire to remove or modify the various impediments that law, usage, and misconception of facts have created and sustained against it. The Royal Horticultural Society, having special facilities for obtaining and diffusing information on all that relates to horticulture, this Conference respectfully requests the appointment by the Council of a Law and Parliamentary Committee for the consideration of the impediments above referred to." Mr. Tallerman then moved as an addendum, "That in the event of the Committee being appointed, this Conference desires to urge the early consideration of the question of railway charges as affecting the growers of fruit and vegetables." This was seconded by Mr. P. Crowley, and also passed.

The remaining resolution was prepared by Messrs. J. Wright and B. Wynne, members of the Fruit and Floral Committees respectively, in consultation with Mr. G. Bunyard as a representative nurseryman, and Mr. M. Dunn of Dalkeith as a representative provincial gardener. After being printed it was revised and expanded by Dr. Maxwell T. Masters, F.R.S., and received his prompt and powerful support. It was to have been proposed by Mr. E. J. Baillie, F.L.S. (of Messrs. Dickson, Chester, Limited), but that gentleman had to leave immediately after reading his excellent paper, at the close of which he expressed the pleasure he had in attending the Conference, and he "thought that the Royal Horticultural Society should be made the centre of a national education for the promotion and advancement of horticulture. It seemed to him that there were resources at the command of the Council which could not be got in any other centre in England, and it was almost a disgrace, if not a disaster, that the best use nationally should not be made of them." These sentiments were much applauded.

Mr. Dunn then rose to propose the resolution that was in the hands of most of the audience, and had a warm reception. He congratulated the Society on the success of the important gathering, the particulars of which would be read with satisfaction by gardeners all over the kingdom. He was not a Fellow of the Society because its proceedings were not of sufficient importance to him and provincial gardeners generally, but if Chiswick were turned to the best account, and conferences of this useful nature held periodically, information of value to all would be obtained, and he would then have pleasure in joining the Society, doing all that he possibly could for it, and he had no doubt others would do the same who did not at present belong to it for the reasons above stated. Here is the resolution:—

"In view of the great public advantages that have accrued from the previous Conferences held in these gardens, and the marked success of the present one, members of the Executive Committee of this Conference, Fellows of the Royal Horticultural Society, and other horticulturists here assembled, who are deeply interested in the Society's welfare and in the important question of developing the progress of scientific and economic horticulture, including especially the fruit-growing capabilities of the country, respectfully

No. 2091.—VOL. LXXIX., OLD SERIES.

submit for the earnest consideration of the Council of the Society the desirability of concentrating the Society's resources to the utmost extent upon the maintenance of the Chiswick Garden, so as to enable it to fulfil its mission as the national exponent of practical and experimental horticulture." (Applause.)

Dr. Masters seconded in a speech of great weight and in cogency of argument practically unanswerable. Messrs. Wright, Roupell and others supported, then Mr. Veitch (the Chairman) rose and said, "I now put this resolution to the meeting, all who are in favour of it will signify the same in the usual manner." Almost before the words were out of his mouth up went a forest of hands. "Now to the contrary. None. Carried unanimously." Thus the last of a successful series of meetings closed in animation and happy harmony, but not before a strong vote of thanks was conveyed to the Rev. W. Wilks, the Secretary of the Society, for his unremitting attendance and active work throughout the week, and to the Chairman of the meeting.

It now remains for the governing authorities to deliberate on the above adopted views of a large body of supporters, and in due time to devise a plan of action on the lines proposed. No one doubts the good intentions of the Council and their strong desire to make the Society popular and useful, and few will begrudge the provision of suitable rooms in London for meetings and administrative work, or to the holding of metropolitan shows occasionally that shall be large enough to command public attention and worthily represent high class horticulture, provided real and earnest action is taken in developing the resources of the garden at Chiswick for the purposes indicated in the resolution.

ROYAL HORTICULTURAL SOCIETY.

CHISWICK.

NATIONAL APPLE AND PEAR CONFERENCE.

OCTOBER 16TH TO 20TH, 1888.

THE FOLLOWING IS A LIST OF VARIETIES TO WHICH CERTIFICATES OF MERIT WERE AWARDED.

APPLES.	EXHIBITOR.
Adams' Pearmain	From Mr. G. Griffin.
"	Mr. C. Turner.
Alexander	Messrs. G. Bunyard & Co.
"	Messrs. J. Veitch & Sons.
Alfriston	Mr. M. Dunn.
Alma Pippin	Messrs. W. & E. Wells.
Annie Elizabeth	Mr. C. G. Sclater.
"	Mr. W. Roupell.
Baumann's Red Reinette	Mr. C. Ross.
"	Messrs. J. Veitch & Sons.
Beauty of Kent.. ..	Mr. T. Bunyard.
"	Mr. J. Roberts.
Bismarck.. ..	Messrs. G. Bunyard & Co.
"	Messrs. J. Veitch & Sons.
Blenheim Pippin	Mr. G. W. Cummins.
"	Messrs. Saltmarsh & Sons.
"	Mr. C. G. Sclater.
Bramley's Seedling	Messrs. J. Cheal & Sons.
"	Messrs. J. Veitch & Sons.
"	Mr. W. H. Frettingham.
"	Mr. H. Merryweather.
"	Messrs. R. Veitch & Son.
Cellini	Messrs. J. Veitch & Sons.
"	Mr. M. Dunn.
Cockle's Pippin	Messrs. Paul & Son.
"	Messrs. J. Veitch & Sons.
"	Mr. H. G. Ocle.
Court Pendu Plat	Mr. W. Crump.
Cox's Orange Pippin	Mr. M. Dunn.
"	Messrs. Paul & Son.
"	Messrs. T. Rivers & Son.
"	Mr. W. Crump.
"	Mr. R. Dean.
"	Rev. W. Wilks.
"	Mr. A. McDonald.
"	Mr. A. Waterman.
Cox's Pomona	Mr. J. Roberts.
"	Mr. G. W. Cummins.
"	Messrs. G. Bunyard & Co.
"	Mr. M. Dunn.
"	Mr. J. Hudson.
Domino	Mr. W. H. Frettingham.
"	Mr. H. Merryweather.

APPLES.	EXHIBITOR.
Duchess of Oldenburg	Mr. J. Watkins.
"	Messrs. J. Cheal & Sons.
Ecklinville Seedling	Messrs. G. Bunyard & Co.
"	Mr. W. King.
"	Messrs. Dicksons & Co.
Egremont Russet	Messrs. G. Bunyard & Co.
"	Messrs. J. Cheal & Sons.
Fearn's Pippin	Mr. C. Howe.
Frogmore Prolific	Messrs. J. Veitch & Sons.
Gascoigne's Seedling	Royal Horticultural Society.
Gascoigne's Scarlet	Messrs. G. Bunyard & Co.
Golden Noble	Mr. J. Hudson.
"	Royal Horticultural Society.
"	Mr. T. Bunyard.
"	Messrs. C. Lee & Son.
Golden Spire	Mr. A. Waterman.
Gospatrie	Mr. C. Ross.
"	Messrs. G. Bunyard & Co.
Gravenstein	Mr. A. Waterman.
"	Mr. H. G. Ocle.
Grenadier	Mr. J. Watkins.
"	Messrs. Paul & Son.
"	Mr. W. Roupell.
Herefordshire Beefin	Messrs. J. Veitch & Sons.
Hormead Pearmain	Messrs. J. Cheal & Sons.
"	Messrs. G. Bunyard & Co.
Kerry Pippin	Messrs. J. Jefferies & Son.
King Harry	Messrs. J. Veitch & Sons.
King of Tompkins County	Messrs. T. Rivers & Son.
King of the Pippins	Mr. W. Crump.
Lady Henniker	Messrs. T. Rivers & Son.
"	Mr. A. McDonald.
"	Mr. C. G. Sclater.
Lady Sudeley	Messrs. J. Cheal & Sons.
"	Messrs. G. Bunyard & Co.
Landsberger Reinette	Royal Horticultural Society.
Lane's Prince Albert	Messrs. H. Lane & Son.
"	Mr. W. Crump.
Loddington House	Messrs. J. Veitch & Sons.
"	Mr. M. Dunn.
Lord Derby	Messrs. C. Lee & Son.
"	Mr. W. Crump.
Lord Grosvenor	Messrs. J. Veitch & Sons.
"	Mr. J. Watkins.
Lord Suffield	Messrs. G. Bunyard & Co.
"	Messrs. Dickson & Co.
"	Mr. W. King.
"	Mr. W. H. Frettingham.
"	Messrs. Paul & Son.
"	Mr. M. Dunn.
Mabbott's Pearmain	Messrs. W. Paul & Son.
Mannington Pearmain	Messrs. T. Rivers & Son.
Melon Apple	Messrs. G. Bunyard & Co.
Mère de Ménage.. ..	Mr. J. Rust.
Mother	Mr. A. Waterman.
"	Mr. J. Powell.
Mrs. Barron	Royal Horticultural Society.
"	Messrs. J. Veitch & Sons.
New Hawthornden	Messrs. J. Peed & Sons.
"	Messrs. G. Bunyard & Co.
New Northern Greening	"
"	Messrs. J. R. Pearson & Sons.
Niton House	Messrs. J. Veitch & Sons.
Northern Dumpling	Messrs. J. Cheal & Sons.
Northern Greening (improved)	Mr. W. H. Frettingham.
Okera or Akera	Mr. T. Bunyard.
"	Messrs. G. Bunyard & Co.
"	Messrs. J. Cheal & Sons.
Peasgood's Nonesuch	Mr. W. Roupell.
"	Messrs. R. Veitch & Sons.
"	Mr. A. Waterman.
"	Mr. J. Roberts.
"	Mr. H. G. Ocle.
Potts' Seedling	Messrs. J. Veitch & Sons.
"	Mr. J. Roberts.
"	Messrs. J. Jefferies & Son.
"	Messrs. Dickson & Co.
"	Messrs. C. Lee & Son.
Reinette de Canada	Messrs. T. Rivers & Son.
Ribston Pippin	Messrs. G. Bunyard & Co.
"	Messrs. T. Rivers & Son.
"	Mr. R. Milner.
"	Mr. W. King.
"	Mr. C. B. Saunders.
Rosemary Russet	Mr. M. Dunn.
Scarlet Nonpareil	Mr. C. Turner.
Scarlet Pearmain	Messrs. J. Veitch & Sons.
Schoolmaster	Messrs. T. Rivers & Son.
"	Messrs. J. Veitch & Sons.
Seaton House	"

CANKER IN FRUIT TREES.

BY EDMUND TONKS, ESQ., B.C.L., KNOWLE, WARWICKSHIRE.

I HAVE been requested by Mr. Barron to contribute a paper for discussion at this meeting, and as the results of some experiments recently made by me appear to indicate that there may be a remedy for that worst of all diseases affecting fruit trees—canker, which is described in the "Herefordshire Pomona" as "the terror of all orchardists and the bane of most orchards," I thought it right to comply with the request. As my own experience scarcely extends beyond my garden, and numerous duties have prevented me from devoting even there that close and continued observation which is necessary for the proper study of such a subject, I should have hesitated to intrude my crude notions in antagonism to the authorities if their views had been clear and definite; but as these are very vague, both as to the cause and the cure of the disease, I venture to state my own. Thompson, in the "Gardener's Assistant," says—"The cause is imperfectly understood, and so consequently is an effectual cure;" Mr. Fish, in "Cassell's Popular Gardening," says—"In fact it may almost be said to be incurable;" and the "Dictionary of Gardening," the most recent publication on the subject, says—"Were the causes better known, the remedy might generally be much easier found." Yet these, and most of the other writers on the subject, according to my idea, indirectly indicate both the cause and the remedy for the disease, the cause being mal-nutrition, the consequence of an imperfect provision in the soil of the food required by the plant; the remedy, the supply of the food which is deficient. These writers inferentially indicate this remedy. For instance, Thompson recommends that "the soil be ameliorated, by trenching and other means;" Mr. Fish, in "Popular Gardening," says—"Lift the roots into higher places of warmth, and better and more immediately available supplies of food;" and the "Dictionary of Gardening" says—"Trees that are badly cankered may be improved by lifting and replanting in improved or better drained soil."

Perhaps the most convenient method of dealing with the subject in detail is to analyse, paragraph by paragraph, all that is stated relating to canker by some recent and recognised authority; that splendid work, the "Herefordshire Pomona," is possibly the best for the purpose, as it may be assumed to contain a summary of the most recent knowledge of all that relates to orchard growth. The first paragraph of the passage in that work relating to canker states that "it is always due to direct injury." In a controversy a clear and definite issue is most satisfactory, therefore with all submission I venture to assert that it is never due to such cause. That canker may appear in parts which have been injured is no proof that the injury caused the canker, although the injury may determine the particular spot where the disease makes itself visible. A well nourished and consequently healthy tree may be injured to any extent without development of canker, while an ill-nourished tree, or, to avoid begging the question, a tree infected with the disease, will develop in all parts the external signs without the slightest injury or abrasion of any kind, and very frequently on parts where, from their well-protected position, such as the angles of the branches with the main stem, it is almost impossible that injury could take place. The coincidence of canker and an injured part is no more proof of the former having been caused by the injury than that a hole in a building through which the flames of a conflagration are first visible is the cause of the fire.

The second paragraph states that "weakness is at the bottom of the canker." This weakness cannot be want of apparent vigour of growth, for I have frequently observed trees attacked which for a number of years have made the strongest growth, yet the disease has appeared before any external signs of weakness were visible; the very vigour of the growth in some cases appearing to hasten the attack in a soil containing too limited a supply of the necessary food, as that supply is sooner exhausted, and the time arrives when the large tree can no longer find within reach of its roots sufficient for its maintenance. It

may be that only one element of food is failing; but every element is indispensable for perfect growth of the whole tree, and that failure would fully account for arrest of growth in parts, weakness, and consequent disease.

The third paragraph is "the tree is old." This may be expressed in other words—the tree has for a long time been growing in the same soil. It is not difficult to realise that in the course of many years a tree may exhaust the most fertile soil. Many seem to overlook the necessity of restoring to the soil what is taken away year after year by large crops of fruit. However rich the soil may have been originally, each crop takes away a definite quantity of the food required by the tree, until in time insufficient remains; then the tree falls, not through age, but through inanition. The same gardeners who leave their fruit trees unfed would think it most unreasonable to expect them to grow their crops of vegetables without manure.

The fourth paragraph is, "or the variety is very old or very delicate." This raises the much-vexed question whether a seminal plant has a finite life, or one which can be prolonged indefinitely by propagation. Experience seems to prove that individual life has a limit, though there is evidence that many seminal plants have a very prolonged existence; however, the limits of this paper do not allow the present discussion of the question. It may be sufficient to say that observation does not lead me to believe that the age or delicacy of a variety renders it more liable to canker when the soil contains what it requires.

The fifth paragraph suggests "that the soil is not sufficiently drained." Canker, according to my observation, occurs equally on well-drained as on ill-drained soils; it is not a question of condition of roots. My own garden formerly contained several trees rapidly succumbing to canker, which, when grafted with other varieties, at once put on healthy growth, made fine heads, and have since for many years been perfectly free from the disease. Each variety requires its own appropriate food; Strawberries afford a very good illustration of this—I have among my friends the reputation of growing this fruit to perfection, yet I had the greatest difficulty in finding varieties which would do fairly in my soil, and after trial of many more than a hundred, have so far discovered only about half a dozen which are moderately successful. British Queen refused to fruit; Dr. Hogg bore fairly as an annual, but did not survive to the second season; in fact, all the Queen race and many other kinds only do more or less ill. Such being the case, it is not unreasonable to believe that some varieties of fruit trees find in some soils what they require, while others do not, and in consequence become subject to canker.

The sixth paragraph is, "or it (the soil) may be too poor." I quite agree with this, as I believe a deficiency in the soil of the necessary food of the tree is the cause of canker.

Seventhly, "The wood may be weak, and is not well ripened, when a sudden frost, especially after rain, ruptures the vessels, and this forms the chief cause of canker." Unripe wood, which is, however, often the result of imperfect nutrition, is productive of much mischief of a temporary nature; but as canker attacks well matured wood, I cannot believe it to be in any case its cause, although when the real cause is at work it may appear on such wood.

In the eighth paragraph the author repeats himself. "Any direct injury, however, to the bark of a tree as from friction of one branch upon another, the pressure of a clothes' line tied from tree to tree, or injury from a ladder in fruit-gathering, may all cause it even in healthy trees." This calls for no further reply than that given to the first paragraph.

Finally, the author states that "Canker commences with an enlargement of the vessels of the bark, more apparent, by the way, in Apple than in Pear trees, and continues to increase until in the course of a year or two the alburnum dies, the bark cracks, rises in large scales, and falls off, leaving the trunk dead, and ready to break off with the first wind if not before removed. The canker shows itself quickly, and if the cause be sought for it will often admit of a remedy. The most usually effective is a good supply of nourishment to the trees affected, together with the removal of the parts injured." I confess that the preliminary symptoms described as the enlargement of the vessels of the bark have escaped my observation; but there appears to be some contradiction in the statement, as while the first symptoms of the disease are described as extending over a year or two, further on it is stated that canker shows itself quickly. However, although I differ so much from the writer of the article in the "Pomona" as to the

causes of canker, we are agreed on the remedy—namely, “a good supply of nourishment to the trees.”

In 1886 my attention was especially directed to plant food, having been requested to write a paper on that subject for the Birmingham Gardeners' Association. In the same year, having noticed that a number of Apple trees in my collection had become unsightly through canker, I marked about a dozen of them for destruction; but while studying the subject of plant food, which involved the consideration of the analysis of various plants, I was very much struck with those of the fruit and wood of the Apple in Wolff's “Aschen Analysen,” the great authority on plant analysis. I found that the fruit contained an exceptionally large proportion of soda and the wood of lime. This at once suggested the idea that my soil might not contain sufficient of one or both of these elements to supply the wants of the Apple tree; therefore I resolved, instead of destroying the marked trees, to give them and all my Apple trees a good dressing of a complete artificial manure which contained full proportions of soda and lime. In the following season, 1887, which was exceptionally hot and dry, either through the drought, the manure, or some other cause, not a spot of active canker could be found; all the edges of the old wounds on the marked and other trees, almost as badly affected, had put out granulations and healed over, and the trees, many of which had previously ceased to extend, made healthy and vigorous growth. Last winter the trees were again dressed with the same manure; this season they have been exposed to the most unfavourable conditions; the soil to a great depth was almost dust dry when they were making their first growth, while an army of caterpillars ruined what foliage was made. Then followed the most continuous cold weather and rain experienced for many years. Notwithstanding conditions so conducive to the extension of disease, there is at the present time still no appearance of active canker. The trees have been carefully inspected by some experienced pomologists who, doubtless, will confirm my statement. Short as is the time during which the trees have been submitted to the treatment, I can only conclude that the arrest of the disease is due to the supply of elements of food required by the trees, of which a sufficient quantity was not previously contained in the soil.

The food required by a plant is a complicated mixture of many elements, all of which are necessary for its well-being. The complete absence of one of them would be fatal; a deficient supply of one would arrest its development, and render it subject to disease. Nothing is more instructive and conclusive on this point than the copies of photographs of plants grown for the purpose of testing the effect of manures more or less complete to be found in treatises on the subject. That of “Ville on Artificial Manures,” published by Longmans, contains many such illustrations, which clearly show that when the soil contains every element of fertility but one it remains absolutely barren. For instance, in a soil without potash the Vine makes no growth.

It remains to say that the manures necessary to restore a tree to health vary as the soils, although the ashes of the wood of the Apple tree contains 71 per cent. of lime—an exceptionally large quantity—it would not be necessary to supply this element on a lime formation; nor would soda be required in a soil near the sea, although on other geological formations or situations a deficiency of one or both may be the cause of canker. Like conditions apply to the other elements.

Various soils require such manures as will supply their various deficiencies; but as it is most difficult to ascertain even by analysis what may be the deficiencies of a soil, the practical way of dealing with the subject is to study the analysis of the ashes of the plant in question, and to use a manure which is composed of these elements; for instance:—

The ashes of the wood of the Apple tree contain—

Potash.	Soda.	Magnesia.	Lime.	Iron.	Phosphorus.	Sulphur.	Silica.	Chlorine.
12.0	1.6	5.7	71.0	—	4.6	2.9	1.8	0.2

and those of the fruit—

35.7	26.1	8.8	4.1	1.40	13.6	6.1	4.3	—
------	------	-----	-----	------	------	-----	-----	---

Ville lays down the rule that soils generally contain sufficient of all the mineral elements except potash, lime, and phosphorus, and the gaseous element nitrogen, and says it is only necessary to supply to the soil manures which contain these four. This may be sufficient for the general purposes of cultivation, but more recent experiments have conclusively proved that the addition of a small quantity of iron largely increases the development of foliage, and consequently of the plant. In dealing with a mysterious disease such as canker I should not leave out either iron or magnesia.

The following formula, which may be varied as circumstances require, is suitable for the Apple tree:—

Superphosphate of lime.....	12 parts.
Nitrate of potash	10 „
Chloride of soda	4 „
Sulphate of magnesia	2 „
Sulphate of iron.....	1 „
Sulphate of lime	8 „

This may be used at the rate of quarter of a pound to the square yard over the whole extent of soil within reach of the roots. It need not be dug in; one effect of the manure may be relied on—if it does not cure canker it will, at any rate, most certainly benefit the trees.

I hope you will excuse me for having questioned some of the conclusions of great horticultural authorities, but it seems that some of these conclusions have been accepted without sufficient examination, as being time-honoured traditions handed down through many generations. Gardeners are, in this respect, perhaps a little too conservative.

I think much may be learnt by occasionally departing from these traditions and making independent experiments in cultivation. My own experience proves that many such experiments resulted in failures, but there is full compensation if only one useful discovery be made or one error exploded.

RENOVATION OF OLD AND FORMATION OF NEW ORCHARDS IN THE WEST MIDLANDS.

BY MR. W. COLEMAN, EASTNOR CASTLE GARDENS.

FIVE years having passed since the R.H.S. inaugurated the first comprehensive Apple Conference, the present Council has wisely decided upon testing the result of that important step by again calling together the friends of Pomona. A small minority at the time thought the exhibition of thousands of plates of Apples would not benefit the growers, but overlooked the fact that these exhibits would bring together not only the growers, but the consumers also. Since that time the growers' prospects have not improved, owing, they say, to the prevalence of low prices brought about by gluts and foreign competition. Buyers, on the other hand, say the supply is unevenly and irregularly distributed, and the price is too high when they purchase from the retailer. Growers say fruit culture will not pay until the land each man holds or occupies is as good as his own, or let to him on a very long lease indeed; but present owners of the soil somehow do not seem to see the force of their argument, consequently the most important work the present gathering has before it is the framing of a scheme of open markets in which consumers can buy first hand at a fair remunerative prices. This is all very well, but supposing each householder is in a position to buy Apples, say from day to day, where are those Apples to come from? Why, we must import them. Actually, we must trust to the Colonies for the produce of a tree which is indigenous to our soil, whilst thousands of acres of land capable of producing the finest fruit is going out of cultivation. To the R.H.S. should attach the honour of taking the initiative in working out this problem, but before the body can move we must learn from reliable men the progress which has been made in the great fruit-growing districts. Living as I do in the county of Hereford, boasting its 27,000 acres of orcharding, where in days gone by thousands of tons of good fruit was lost, wasted, or converted into indifferent cider, I am able to form a pretty correct opinion of our own progress, and although less rapid than I could wish I may say it is fairly satisfactory. Cider drinking amongst the working classes since I first knew the county has gradually decreased, consequently small parcels of the rosy Tom Putt and other useful Apples alike good for cooking or vintage are stored for daily use by all the members of the grower's family. If not wanted, why then they are sold to dealers, who make a profit for conveyance to retailers, who also make another profit, and that a heavy one, from their customers. Although a slight step forward this state of the case is not quite satisfactory, neither will it be until a powerful fruit growers' association, which should be the outcome of this Conference, has established a network of markets in all provincial towns as well as in London, markets in which producers, as in all parts of Paris, can meet face to face with consumers without the aid of so many middlemen. In fruit-growing counties like Hereford, Worcester, Gloucester, Kent, Devon, and Somerset these local markets should be well supported, as we gather from statistics that three-quarters of a million of money is sent out of England annually for Apples alone. If landowners, hitherto blind to their own interests, and legislators now take up the matter, I see no reason why growers should not go forth to the production of an article which the public must and will have, and so keep the money at home. Our climate is all that can be desired for the growth of fresh crisp fruit,

not quite so highly coloured or so large as picked samples from the Colonies, but large enough to command top prices when well grown and packed and properly marketed. There must be no shaking from the trees, but the cream of the crop must be hand-picked and honestly packed as firsts and seconds. The residue or refuse, which added to the best, would increase expenses and pull down prices, would then remain at home for various purposes.

Mr. Knight, the great physiologist and hybridist, who worked so much in Hereford and Salop, proved by analysis that some soils, even in these favoured counties, were preferable to others for producing Apples of dense gravity and full of saccharine matter. The late Dr. Bull, of whom Hereford should be proud, following in his wake, corroborated all that Knight had said, proving, I think satisfactorily, what past generations of shrewd men had found out for themselves, both as regards the quality of the fruit and the constituents of the soil which should be chosen for Apples, also for Pears. The conclusions at which they arrived were these: The light thin soils will not grow the best Apples, therefore those who would plant a successful orchard must choose a deep stiff sandstone loam if they have the opportunity of doing so. All the orchard land in this county is not alike good; indeed, some is very bad, but the soil here, as in Devonshire, which produces the best fruit owes its fertility to the plentiful supply of lime from the marl or cormstone; to its great depth and sustaining nature. Scientists who will may peruse the first part of the "Herefordshire Pomona," or they may follow Mr. Rivers through his exhaustive address delivered at the Crystal Palace, but my remarks, necessarily brief, will guide plain practical planters to the best spots for new plantations.

Having been honoured by an invitation to contribute a short paper upon the Apple, I have determined to confine myself to the west midland orchards, in which, I am pleased to repeat, some progress has been made since the first Conference was held in 1883. Draining, grubbing, grafting, and planting are still going on, but much remains to be done before we can invite inspection. Although the Apple is a long-lived tree and perfectly hardy in all its parts save its flowers the occupants of many of our oldest orchards, crippled by age, bad usage, and neglect are past recovery, and should be cleared away, but the ground they occupy should not be replanted if better or equally good sites can be found for new plantations. Other orchards, again, containing thoroughly sound young trees, although of inferior sorts, after the grubber's axe has passed over the land, may be converted by grafting and resuscitated by draining and top-dressing. Some of our oldest orchards which date back to the Wars of the Roses contain a great number of wildings or kernel fruits of no value to the owners even, whilst younger plantations are crowded with healthy vigorous trees, at one time supposed to be Norman, but now proved to be English seedlings, no better than the stocks used in large nurseries. Upon the first I would not spend money, as they are too old for grafting, too old to pay rent, too old for anything save loss and disappointment. The second I would behead and regraft with choice varieties which have been proved in the locality. Confining myself to old orchards now existing or languishing in the western counties, I may close my remarks upon this head by saying, Cut down all useless trees, thin out the heads of those worth keeping, cleanse the branches and stems from moss and insects, regraft sound healthy trees into good market sorts, and see that the drainage is satisfactory. I will not presume to inform practical men who may deign to read my remarks that sound, deep, naturally drained orchards are better than others which require artificial treatment, and that a certain quantity of moisture in the soil is absolutely necessary, but on no account must it be stagnant. All gardeners are well acquainted with the fact that soils too dry produce fruit that is small and mealy, whilst water-logged soils are several degrees colder than others of similar texture that are free from this root-chilling poison. They know, moreover, that warm summer rains run off the surface, whilst the sun acts very slowly in raising the temperature of the wet subsoil in which deeply seated roots soon perish, and those nearest the surface are little better off, as they do not commence fresh action much before midsummer. Drainage, all good cultivators assert, is the first essential in the preparation of new orchards or in the renovation of old ones, and why? well, simply because the removal of stagnant, if not putrid, water and the introduction of fresh air raises the temperature of the soil from 3° to 5°, a condition which not infrequently forms the dividing line betwixt success and failure.

So far my remarks have been confined to old orchards, planted haphazard upon all sorts and conditions of badly prepared land, as well as in unfavourable situations. The best of these may be retained for a time, upon the principle that half a loaf is better than no bread; but the majority of them must go, and young ones must

spring up before we can hope to realise an average £10 an acre, or compete with the colonists in our own markets. Some years, as many present know, have passed since horticulturists commenced agitating, but the good seed which was intended to put three-quarters of a million of money into the British farmers' pocket for a long time fell upon stony ground. Some recently has taken root, and far-seeing landowners are now putting our theory into practice by offering land upon conditions that will induce capitalists to invest in fruit culture precisely as they do in coal and iron. In this and the adjoining counties good landlords are raising and distributing to their tenantry Apple and Pear trees by thousands. These mostly are standards on free stocks, the only class of tree suited to pasture and arable land. Nurserymen, again, who have brought propagation up to a fine art, are producing standards and dwarfs by the million, and these surely in a few years should make their mark. Meantime, a complete network of markets, I insist, must be created throughout the kingdom.

From the preceding remarks those who run may gather the fact that I do not set much value on the thousands of acres of ragged, decrepit, moss and lichen-laden trees, but until the new plantations come into bearing we must make the best of them. Then, with Gladstonian vigour, we may hew them down, and let the Apple-sick sites go back to Hops, corn, and pasture. Upon this principle change of site may be worked precisely as gardeners now manage their Strawberry plantations, and with similar results. As I venture to say, one acre of modern orcharding will beat ten of the old—at least, in the West Midland counties.

Already I am afraid my paper is too long, but having warmed to my subject, I should now like to say a few words upon the formation of these modern orchards. I might divide them into several parts, such as aspect, site, soil, preparation, planting, the best style of tree manuring, mulching, pruning and protection, gathering, storing, packing, and marketing, but my time being limited, my words must be brief and general.

Aspect and site being so closely dovetailed together these I will not attempt to separate. All gardeners, I believe, are pretty well agreed that a south aspect is best, as trees in this position ripen their wood well, and produce fruit of the highest colour and quality. The Apple, however, being perfectly hardy, the quality of the soil must not be lost sight of; neither must altitude and shelter from north and east winds be repudiated. Under these circumstances, the soil being deep sandstone loam resting on marl, and naturally drained, I should not object to a point east, or any other aspect round with the sun to full west. The latter, however, I should prefer, and for these reasons; although western gales in this part of the country do some damage, it is well known that if plants are exposed to the first rays of the morning sun when they are frozen they will suffer, but if they are shaded until they are gradually thawed by the rising temperature of the air they will stand a few degrees with impunity. An orchard open to the east or south-east is almost sure to suffer an attack of spring frost when in full flower or setting, whereas one with a western aspect, which does not receive the sun until the temperature has risen and dispelled the frost often sets and carries full crops to maturity. Hardly a year passes in which the gardener does not find early crops of all kinds are safer and finer upon west borders than upon others. Therefore I think few will deny that his experience is of great value to the planter. The site, I may say, should be above the line of fog, and it should not be too near or on a level with water. If naturally drained much time and expense will be saved, otherwise this operation must be well carried out as a preliminary to preparation. This may be performed in two ways—viz., by trenching two spits deep for pyramids or bushes, or by taking out large circular stations on grass or arable land for standards. If trenching is decided upon, the bottom spit, if heavy and inferior, should not be brought to the surface, but it may be ameliorated by the addition of burnt clay from the drains, by road-scrappings, or any other fresh friable material short of rich animal manure. This, unless the staple be very poor, I would keep back for use as a mulch after the trees are planted. On all ordinary loams young trees grow fast enough at first, but the time comes when they must be fed, otherwise they cannot be expected to yield year after year fruit of the finest quality.

In the preparation of stations for standards on grass or tillage ground, I would throw off the top spit 9 feet in diameter, break up the bottom, and throw out clay or bad material to be carted away or burned. If cold and at all unfavourable to root growth, exposure of the soil for a few weeks or months would greatly improve its quality. Otherwise, after correcting the bottom spit, that thrown off first, turf included, with anything in the way of road scrapings or old lime rubble added, may be chopped in until the hole is quite full or a little above the ground level.

A stout stake should then be driven down to the solid bottom as a support for the tree when planted.

Planting may be performed at any time from the beginning of October up to the end of April. Autumn, however, is best, as the roots at once take to the soil and the trees make a fair growth the following summer. October and November undoubtedly are the best months—that is, provided the land is in perfect condition and the weather favourable; but so important is getting the trees into the ground when it is fairly warm and dry, that I would rather defer planting until April than risk placing the roots in a pasty medium. Trees of home growth—that is, from one's own nursery, which every fruit grower should have, may be planted much earlier than others brought in direct from a distance. All trees should be carefully divested of faulty or injured roots by a clean cut with a sharp knife; they should never be allowed to become dry, and each root and fibre should be spread out in a horizontal position, lightly covered, and watered home.

In the arrangement of trees, the rows, if convenient, should run from north to south or north-east to south-west, as three out of the four sides then receive an equal share of sun and light. The old fault of planting them too close should be carefully guarded against, as good fruit cannot be expected when the heads grow into each other and the roots are constantly shaded. Standards of upright-growing varieties may be placed 30 feet apart each way, whilst 40 feet will not be found too much for spreading trees like Flanders Pippin and Blenheim Pippin. Trees, again, of one variety, or a similar habit of growth, and which ripen their fruit at the same time, should be kept together or in rows, alternating with others of a spreading or upright character. By observing this rule at the outset the general and orderly appearance of the nursery will be greatly improved, and much time and labour will be saved when gathering the fruit. The same rule applies also to pyramids and bushes which, by the way, should have plenty of room for extension in every direction, as no extensive planter can afford to prune close upon villa garden principles, especially when the best of the fruit is cut away by the process. Thinning the shoots and branches annually of course is necessary, but beyond this and maintaining the balance by tipping a gross shoot, I should let each tree go. The distance apart will depend upon the kind of stock, as trees on the French Paradise may be grown for years at distances of 4 to 6 feet apart each way. On the English Paradise or Doucin, which I like best, they grow stronger; consequently more room is required. Twelve feet from row to row, and 6 feet from tree to tree, will give them room for a long time, but eventually it may be necessary to transplant every alternate tree, when those left will stand equidistant, viz.—12 feet from stem to stem. Some I know plant much closer, but when it is borne in mind that a well developed head turns off not only more but better fruit than a small one, abundance of room is a decided advantage. Moreover, plenty of space favours a spreading growth, which keeps the heads near the ground, safe from wind and easy of access for pruning, manipulating, and gathering. When standards are planted they should be well secured to the stakes previously driven, but in a way that will allow them to settle with the subsiding soil, otherwise the roots will drag and strangle. If on pasture land, they should be protected from sheep and cattle, and the orchard itself must be fenced and wired round to keep out hares and rabbits.

VARIETIES.—The only point I must now venture to touch upon is the selection of varieties for special soils, situations, and purposes. A few years ago we planted very early sorts for coming in before the American importations, but this is now over, as the quick run, and summers hotter than our own combined, enable our friends to be abreast of us at the beginning, as for a long time they have been at the end of the season. Our only way out of this dilemma, as I have before observed, is high cultivation. We have a climate which ripens fruit crisp, tender, and juicy, not quite so highly coloured, perhaps, but in my opinion superior to the general run of American. We have the soil which, thanks to yearly tenancies, nobody cares to till, and we have the ability. All we want is quality, then it matters little whether we market early or late, always provided we confine ourselves to a few of the best sorts which do well in the locality. This hackneyed phrase for a long time puzzled would-be growers, who said, Where must we look for anything better than a Suffield or a Blenheim? Well, I am not sure that anyone requires anything better, but if they do they must just look into any of the great well known nurseries about the end of September, and there they will find thousands of trees of all the leading kinds carrying fruit of the highest quality. Some of these on dwarfing stocks—just the thing for the garden or home nursery—will

be loaded with large, bright fruit, of which at the present time we ought to have 100,000 tons ready for storing. They will also find standards on free stocks specially prepared for planting on pasture and arable land. From these they may select scores or hundreds of trees of one sort, and so on of another, but on no account must they select one or two trees each of a hundred sorts, as this plurality is a great drawback in commercial culture. Very early sorts generally go direct from the trees to the market; medium and late sorts must be stored in dark, cool fruit rooms or dry cellars, and this accommodation, or the want of it, must be the guide in making a selection.

Gathering, storing, and marketing hitherto in the western counties has not received proper attention; but a great improvement is now taking place, and the day I hope is not far distant when ruthless shaking the boughs will be looked upon as a barbarous custom of the past. Apples worth growing are worth hand-picking, and when hand-picked they are worth sizing—that is, dividing into two classes before they are stored or sent to market. The best only should be sent away; seconds may be retained for home use or consumption in the neighbourhood. There should be no mixing of sorts, or good and bad together, but one uniform quality should prevail. Buyers in this part of the country still stick to their pots. I do not mean earthenware, but wicker, which hold from five to seven pecks each; but invariably they sell by weight, and this, I think, is the fairest way, as anyone can compute the value of a ton of Apples. Before Apples are hand-picked for storing they should be ripe, that is to say, the kernels should be brown and somewhat loose in their cells. The fruit, moreover, should be perfectly dry and free from spot or blemish, as one black sheep soon demoralises the flock. Once put away, the less they are turned or handled the better, especially when sweating or during frosty weather.

If the store room is fitted with lath shelves, the choice varieties should be placed one, or at most two, layers thick, but late sorts grown in great quantities may be laid upon dry floors in greater bulk. They may also be stored in dry flour barrels, which should be labelled and put away in a low even temperature for the winter. Good aristocratic store rooms are rather expensive, but a cutting driven into a dry bank and covered with thatch, with double doors at one end, will make a store equal to the best and most elaborate in the kingdom. Resinous wood should never be used in the manufacture of shelves. Neither should hay or straw be admitted within the walls, as all these materials impart a disagreeable flavour. Dry fern, on the other hand, may be used for covering purposes, but very little of this will suffice where frost, and more especially heat-proof, stores are properly constructed.

FRUIT PRODUCTION AND DISTRIBUTION FROM A PROVINCIAL POINT OF VIEW.

BY MR. E. J. BAILLIE, F.L.S.

I FEEL some explanation is needful for the introduction of a paper which does not profess to be technical before such an audience and upon such an occasion, but I have long held the belief that, whilst we pay strict attention to the practical points, or strictly technical details which rightly claim the closer attention of the specialist, we ought to give some prominence to particulars which, we may say, constitute the fringe of a subject.

Whilst these are, perhaps, of a too general character to possess much charm for the person intent upon some particular detail, they serve to put us in touch with the public, and thus are helpful in removing popular prejudices, for there is a sense of separation somehow between those to whom we look for fruit consumption and those to whom we look for fruit production.

I knew, too, that there would be gentlemen of wide practical experience whose names are in the front rank of the honourable record of present day horticulture, taking active part in these proceedings, and I thought that they would treat of particular phases of the subjects irresistibly suggested by a "National Fruit Conference."

In this I was perfectly right. Whether I was right in my choice of a subject, for the reasons already stated, remain to be seen, but I venture to think from what I know of the good nature of those connected with garden pursuits, I can claim your indulgence if I fail to gain your approval; and if any remarks of mine are such as to provoke hostility of thought, you must please put them down to provincial prejudice, or, may I say, to that simplicity which is one of the most prominent attributes of raw rusticity.

I appreciate the difficulty of saying anything new on the question, but I shield myself behind the fact that the reiteration of a truth is not a needless undertaking until precept is put into practice. So long as

we pay our millions of money into other hands for produce which could come from ourselves we are quite safe in assuming that there is yet reason for action.

Coming up from pastoral pursuits to this great centre of crowding, clamouring life, how can one express the feelings that somehow naturally force themselves to the front? They may be said to be somewhat thus: Here you have in your great crowded centre somewhere approaching 5,000,000 of souls. This area, with its vast population, has practically grown nothing but bricks and mortar save the trees and flowers in its beautiful pleasure parks and its promenades; and if this great centre were dependent upon its own resources for market produce for its daily needs it would very quickly have to answer its children's cry for bread by giving them stones.

This great multitude must take some feeding. The open country of the shires gives garden ground enough for all. The earnings of the provinces find their way largely into the pockets of the landowners, and they, in the natural order of present day methods, spend a large portion of their time and the greater part of their wealth in London. There is a kind of feeling that, seeing so much of the wealth of the country comes here, more might be done for us and less for the foreign coquettes who court your favour and gain your sympathy and support for such things as we can grow quite satisfactorily at home.

I do not at all fear the bogey of foreign competition. This is, I remind myself, a National Conference, but the subject is really universal. The idea involved in fruit production and distribution is too large for a nation. We cannot, for instance, grow the Orange. We should not like to dispense with it, therefore we invite the foreigner to send it to us; but we can produce Pippins; then why should you raise your eyes above the beautiful fertile plains, say, of Kent and Sussex, and with the telescope of a false economy find beyond the seas, in the broad acres of America, Canada, Australia, and elsewhere, the admitted beauty of fruitful plains, but also an added imaginary beauty, really nothing beyond what you could have seen without the glasses within the confining hedgerows of our British orchards?

We must, however, get somewhat nearer the chief points to be considered. We must drop figure and get to facts. We think we may safely start with an aphorism. Cultivation of the land is the basis of all economy. Mother Earth, after all, nurtures the whole family of the human race. "The profit of the earth is for all; the king himself is served by the field." The political economist and the social scientist can touch no profounder problem than the problem of production, and we cannot escape the consideration of the threefold aspect of the laws of life which all rightly civilised people recognise:—

- 1, The population must be properly employed.
- 2, The people must be clothed and fed.
- 3, As a necessary condition the land must be cultivated and cropped.

Now we have already reminded ourselves that we have to take ourselves outside the limit line of streets and alleys and get into the open country, where we find agriculture and horticulture side by side, sometimes overlapping each other, but always mainly concerned with these four phases of occupation:—

- 1, Cattle production, under which I would include the rearing and breeding of all animals for slaughter or other purposes.
- 2, Wheat production, under which head I would include all arable farming.
- 3, Dairy farming, under which I would include all milk, cheese, and dairy products.
- 4, Fruit farming, including the production of vegetables and other market produce of this character.

The consideration of the question of supply immediately brings before us the question of demand. We ask ourselves, What is demand? Why is it needful to produce? An elementary question truly, but one which has been handled peculiarly by the jugglers of political and other economists. Briefly, produce is needed for the maintenance of political life. It was easy for the French wit to say, "Give me the luxuries of life, let who will take its necessities;" but necessities are—necessities! We then ask ourselves upon what can good health and happy life be best maintained.

Well, I fear we should here quickly get into conflict of opinion. Doctors differ. I am justified, however, upon the grounds of science and of experience in asserting that men can live, and live healthfully and happily, on cereals and fruit, so that a Wheat farm and a fruit farm would meet all national needs. Cattle farming we are not now concerned about.

I know I strike a chord which may not be one entirely of harmony

in a meeting of this character, when I say that man can derive all needful sustenance from the cereals and fruit, that is to say, humanity has in fruits—for cereals are fruits—all that it needs. Mark, please, I do not say it has therein all that it craves, but all that it needs.

Now, if in any other machine than that of man (if you permit him to be so considered for a moment), heat, essential for its going, could be got from deal logs, and it was fed by the engineer with mahogany French polished, and refined oils, we consider it strange. Of course he might do it if he liked, but should we wonder why? Man, so far as his means permit, may, too, feed on what he likes, but the economist must first consider essentials, not preferences or prejudices. But I find I must push forward, for I dare not pursue fancy too far in a paper of twenty minutes length.

After the determination of what is essential for the maintenance of life we must consider the labour question. Which of the four systems under which we have divided the question of cultivation employs the largest amount of labour, and in which are our labourers the most happily and healthily engaged? Unhesitatingly, with firmest decision, we answer, In fruit production. Quite lately I, by chance, became the travelling companion of one of the largest agriculturists in our county, whose farm lands had been laid down to grass. He had given up corn for cattle, and he told me that as a result fifteen cottages were at that moment standing empty. So far as farm labourers were concerned he had no further use for them, and they had gone—where? He did not know, but in all probability to swell the already congested population of the towns. How are we to get our open-faced, honest-hearted country population back to the green lanes and the gardens?

One of the best methods is the development of the industry of fruit production. But is our climate such as to encourage safely the cultivation of hardy fruits? Let us not commit the often rash errors of a too eager enthusiasm. I do not know which most to pity or blame—the blind optimist who to every question suggesting the possibility of big profits, Arcadian delights, and a contented population always basking in the sunshine of ease and unconcern, replies, "I answer enthusiastically—Yes;" or the poor pessimist who says our Apples are only Crabs; that there is a worm at every core; that the glory has departed, and we are all tumbling into the Slough of Despond.

But there is a *via media*. It is possible to make the crooked straight, and the rough places plain, if we only set ourselves heartily to find the more excellent way.

Hardy fruits can be grown, and well grown, in this much-despised climate of ours; but, like everything else, it must be done properly. No more subtle sweetness, crispness, and altogether right flavour can lurk beneath the skin of Apple or Pear than can be found in the flesh of a British-grown Cox's Orange or Ribston Pippin, or some of our best Pears, and no sprightly sauciness of brisk acidity can be found in the often insipid flavour of many of the foreign sub-acid Apples to compare with that of a northern grown Keswick or Lord Suffield.

There are those about us, and apparently warmly interested in this movement, who go to extremes in both directions. In this problem of production let us remember we have all tastes to suit, all palates to please, and therefore a wide range for our eating. One cannot help being amused to read that somebody's Pippin, which is the Apple of the future for the essence of its sweetness and syrupy juiciness, to which sugar would be a superfluity if not an absolute detraction; and in another week's issue of the same journal the merit of somebody else's seedling, which is to be the Apple of the future, is found in and founded on the fact that its beautiful tartness of flavour is such as absolutely to defy the seductive influence of sugar or syrup, bringing it to the dull level of the popular palate which can only take its Strawberries when reduced to a kind of saccharine paste, which can only take Currants as preserves, or Cherries in brandy.

So long as opinions differ so widely we need not fear the unavoidable influence of climate in any of the home districts upon the qualities of our British-grown fruit.

Whilst admitting of a certain amount of healthy variation in the quality of the fruits I would venture to say that the error of the past has been rather in the multiplication of kinds than in the other direction. Some people have prided themselves upon having as many varieties as they can count trees in their orchards, but I could never see the full force of the benefit of such possession. It is well to choose but few kinds, letting them be such as are suitable to the district and such as commend themselves as market favourites.

For instance, in the larger Lancashire towns Apples of a brisk sharp flavour find much readier sale than the sweeter fruits for which there may probably be greater demand in the south. If you can sell at

Cottonopolis Keswicks or Lord Sufields by the ton why not grow them by the acre rather than coddle with somebody's new seedling said to surpass the Newtown Pippin in its sugary flavour when the season is favourable enough for it to fruit? Meet the demand of the district and proceed cautiously; extend as rapidly as you like, but carefully.

If it is worth doing at all it is worth doing well. Do away with worthless incumbrances of the ground. A good fruit is as readily grown as a bad one. This is the crux in the provinces.

If time permitted me to draw you a picture of the typical farmer's orchard you would not wonder that fruit-growing was a feeble industry in many places. Such so-called orchards are, many of them, excellent hunting grounds for the entomologist or the cryptogamic hotanist, whose special attraction is amongst mosses and lichens. Most of the trees are favourable specimens of artistic antiquity. The only evidence of anything approaching a pruning process which I have ever witnessed amongst some of them was the wreckage of the storm or the broken boughs at Appletide which had snapped asunder under the weight of the ladder against them.

If the orchards are carelessly kept—or carefully unkept—it is an equally peculiar fact that when fruit is home by the trees it seems to suggest no necessity for right handling. Mark Twain in one of his sketches enlarges, I think, upon his experience in days when he was assumed to have the editorial charge of an agricultural paper, and in answer to a correspondent, he told him he thought he had himself to blame for the condition of his Turnip crop, the defects of which he had just described. "You should wait," said Mark, "until they are nearly ripe, then get up the tree and shake them down." He found that was not the way Turnips were treated, but the editor had probably seen a country farmer gathering his fruit, for that is precisely the method he follows on such an occasion. All this and much more must be changed before British fruit-growing takes the important place to which it is entitled.

The present position of the fruit question in the public mind seems to be that fruit is now used to grace the tables of the wealthy or to add a kind of fashionable finish to the dinner of the fairly well-to-do; but it is seldom regarded as food pure and simple, though such it really ought to be.

Let anyone having an interest in philanthropic work cause District Visitors or City Missionaries to make inquiries amongst the poor of the large cities, and you will find that fruit is almost, if not entirely, absent from the list of dietary articles from which the food supply of those who live in the narrow streets and the crowded alleys is derived. I have gathered statistics in our own district, and was startled to find how the poor live even in a provincial town, where a person placed at its centre might get between the hedgerows and into the fields well within half an hour. Ignorance and prejudice have helped to maintain this condition of things, for they have only the bare idea that fruit is palatable, and have no idea that it is also invigorating and healthful.

For the proper and complete developments of the fruit movement in this country we must have all our forces to the front. There is a really steady demand, we are told, for the best fruits carefully gathered and well packed, at most remunerative prices. That seems to meet the want in certain directions, but we must encourage those educational and moral movements which have for their aim and object the inculcation of habits of thrift and health amongst the masses of the people.

There should be, and must be, a very largely increased demand for the home product, and the home product will be then forthcoming; and this brings us closer to some of the features we have to face in the question of distribution.

This opens up as many avenues of thought as the question of production—perhaps more, for in the question of production we deal largely with matters of conjecture, for we can never know the end of an unfollowed course, and if you advocate two methods or fifty you would find followers for each; but the question of distribution brings us at once face to face with the problems of £ s. d., and with the conditions of market operations and regulations.

I do not intend to take up the time of this meeting by attempting to deal with one of the most damaging conditions which we meet with as a most serious obstruction in the very outset, that, namely, of the railway rates. Nor do I attempt to touch upon that other forcible deterrent—the question of land tenure; but this and the railway question will, I find, be dealt with in separate papers; but until some sweeping change is made in the present system of railway charges it seems that the British fruit-grower will find his industry shackled and weighted to such an extent as to prevent his making a profit at all

commensurate with that which he is helping to put into the pockets of the railway shareholders.

Next to the railway question we require the establishment of some responsible agency or agencies to take up in combination the conditions which cannot be successfully fought single-handed, and this agency should not be merely commercially protective, but also educational. Amongst other matters it should collect and publish careful data as to districts, climatic influences, meteorological notes, and such other intelligence as would serve to guide. This body would have to be influential and potent, for the power of monopoly is, as matters now stand, almost invariably against the producer and the consumer, and in favour of some intermediate agent, whose name is legion apparently, and whose presence may be necessary for the discharge of commercial enterprise, but who ought to be regarded more in the capacity of a carrier or an agent rather than a trader or merchant.

Next we require the provision of centres of sale. Endless time is lost by the producer in his effort to find a market, and neglect at home is consequently unavoidable. It is essential that persons having produce to sell should be brought into contact with persons requiring to purchase, but we have at present no such facility. Cheshire has its cheese fairs, established by the order of a council, and the staple product of the county therefore holds its own in spite of foreign competition. Birmingham has its Onion fair, but I do not know of a town in England that has its fruit fair.

Then we ought to be able to purchase fruits by name as to variety. To the farmer mind not so many years ago everything green upon the face of the field was grass. To the mind of the average citizen or citizen's wife anything that is round, and that has been plucked from a tree in an orchard, is an Apple; it matters not whether it be a flavourless Crab or a Golden Pippin—it is an Apple; but we want to initiate the public into a knowledge that certain Apples carry with them certain qualities and certain flavours, and we want then to show that precisely what they want can be supplied. There are advertisements in connection with domestic commodities, which seem to suggest the grave importance of your being sure you get somebody's starch when you ask for it. The same caution should be applied in the pomological department, and when the cook finds out that a certain kind of Apple can be depended upon for a certain quality we should find the beginning, too, of a more definite order of things.

Another great impetus to the home product might be insured if at railway stations and other places where the public gather themselves in masses English fruit could be obtainable instead of the everlasting French Pears and American Apples; and I should like, if those ugly iron *impedimenta* called "automatic deliveries," or some such wonderful name, are to be tolerated, that they should, in response to the penny and the push, give orchard Plums instead of sugar plums, and Apples and Pears in preference to chocolate or candy.

Another idea that has long possessed me is the idea of selling of fruits from sample. According to present methods of distribution a producer gathers his fruit and carries it away to the markets, there to stand with a load of it until it is distributed. Those who have learned the art of modern marketing have found out that prices decline as the day wears on, for the grower does not desire to cart the piece of a load home again. On the other hand, there may be a system of "topping"—I may be excused if I explain (for of this my present audience is doubtless ignorant) that this implies a process, possibly accidental, by which the larger, better fruits in a basket gravitate towards the top! This is, of course, open to the suggestion of unfairness on the other side, but if the grower submitted samples of his fruit just in the way the farmer does who has grain or seeds to sell, an immediate relief would result.

A farmer does not think of carting the yield of his grain fields to the open markets, but asks the merchant to buy upon the sample placed before him in the market; and he can sell or hold as he then thinks best. He would then be in a less likely position for the imposition of injustice.

Then I think is the interests of distribution our leading agricultural and horticultural societies—agricultural societies especially—should recognise the industry, and admit home fruit products into the schedules of subjects for competition. I am glad to observe that the Royal Agricultural Society of England has taken up the matter, and hope other agricultural societies may now be induced to follow. It is likely that more good will arise from sources of this character than through minor efforts of less prominent bodies, as the subject would then be considered along with the problems of land cultivation in their more important and varied aspects.

I must not forget to include the all-powerful press. We have natural

friends in the editors of horticultural publications, but I am glad to see the general press of the country is now taking an interest in the question. Whilst many newspaper readers are evidently competent to take an intelligent view of the matter, there are some who seem to discern in the agitation something like the sectarian movement of a new faith, for which they have quickly set themselves to invent the name of the "Faddist." Well, let it be so.

If we are to get public attention called to the question, we may hope that the long-delayed interest will be fairly and fully aroused, and whilst we rejoice in the peace and prosperity of a nation preferring pruning-hooks and ploughshares to swords and spears, we shall yet the more rejoice when we gain the greater victory and proclaim the wider conquest of the sickle and the spade.

(For continuation of Conference matter, see next page.)

CYPRIPEDIUM TESSELLATUM PORPHYREUM.

THIS is one of the most handsome of the Veitchian hybrids, and as recently shown by Mr. B. S. Williams at a meeting of the

FIG. 43.—CYPRIPEDIUM TESSELLATUM PORPHYREUM.

Royal Horticultural Society its merits were very apparent. It was obtained from a cross between *C. barbatum* and *C. concolor*, but the characters, as to colouring especially, of the former predominate with a slightly altered shape. The peculiarly rich purplish tint has however, become intensified, and renders *C. tessellatum porphyreum* conspicuous amongst the *C. barbatum* family.

STANHOPEA TIGRINA.

STANHOPEAS appear to be amongst the neglected Orchids, the short-lived character of their blooms fully accounting for this unfavourable attention; but in spite of this failing they are worthy of some consideration, as their culture is of the easiest description, and their flowers never fail to command admiration. They are, moreover, what may be termed amateurs' plants, for any ordinary stove will suit them, and they are not so easily killed by injudicious management as many exotics that are cultivated by the amateur grower. I recently noticed a vigorous specimen of the above species in the gardens of Fair Lawn, Frome, which had several branching spikes, the strongest producing eight of its richly marked and wax-like flowers that, together with those of four or five other clusters formed, quite an imposing picture. They are grow-

ing in a basket, the only convenient method of culture, as Stanhopeas have the peculiarity of producing their blooms from the base of the pseudo-bulb, the pointed flower spike piercing its way through soil and hanging beneath at distances varying according to the strength of the plant. The blooming period can be considerably extended if several plants are grown. When in bloom they should be kept cool and dry, as this will tend to preserve the flowers to the fullest extent, but at the most they will only last a few days. They require suspending near the roof and abundant supplies of water given during the growing season, and they do not require frequent disturbance at the roots.—W. S.

NARROW VINE BORDERS.

THE article by your able correspondent "Spectator" on the above subject was most interesting, especially with reference to the materials used in the construction of borders confined to such narrow limits. A gardener with whom I am well acquainted, and who is an excellent Grape grower, recently wrote to me confirming the opinion of "Spectator," and says he has great faith in the use of broken bricks for Vine borders either when forming new or renovating old ones. It is, however, since he has adopted the narrow border principle that their value has been more particularly observed, these naturally affording greater conveniences for observation. The top-dressing he applied for this season was a simple mixture of lime and broken bricks, in the proportion of two-thirds of the former to one of the latter; and the surface of his borders are at the present time a perfect network of those large white roots, so desirable and pleasing to any Vine grower, and which "Spectator" describes as being so numerous in the sandy soil of one of the borders alluded to in his recent contribution. Another item which he attaches importance to is that of making the soil quite firm. Mallets are always brought into use when any additions are made, whether it is in making new or when a top-dressing only is applied; and the Vines amply demonstrate the value of a firm soil, the canes produced in such being exceedingly short-jointed and sound in texture. This experience is not gained from one or two seasons' observations, but has been the practice for many years, and that, too, with unvarying success.

Abundant proof is given by "Spectator" that costly mixtures are unwarranted in the construction of Vine borders, and those who have such work in hand, or are contemplating it, are indebted to your correspondent for bringing forward these successful records of inexpensive Vine culture. No doubt further proof can be produced by able writers who have expounded the Grape scalding question so thoroughly, and as the present is an important period of the year for the work in question we may yet be favoured with their opinions on this topic also.

It would be interesting to know if the broken bricks or similar material have been used by other readers of the Journal, and with what results: the gardener under notice asserting that had he the necessity of making a new border he would not hesitate in using fully one-half of them if the soil was of a heavy or fibreless character.—W. S.

RUDBECKIA PURPUREA.

It gave me pleasure, as no doubt it did to many more, to see this fine perennial so faithfully illustrated in the last issue of the Journal. The peculiarly pleasing shade of colour which renders it so conspicuous in autumn is without a rival in the borders; indeed so distinct is it, that I believe I am correct in saying the colour is unique among hardy herbaceous plants. The plant is a profuse flowerer, a fact which only enhances the value of one of our best border plants. I can readily imagine how such an uncommon colour would attract attention at Kew by the admiration which my own little stock has this season created, with hundreds of flower heads in all stages of development. It will be some years probably before it reaches the gardens of all who are anxious to have it, for its progress is rather slow. Bees are excessively fond of this species, and gather around it in great numbers on all bright days. Seeds, however, are rarely obtainable. Repeatedly have I endeavoured to procure some, but have not succeeded, and the very few which constitute a packet from foreign sources have never produced plants at all. Division, therefore, is the only safe method of increasing the stock, and as the rootstock is hard and woody, this must be done with care. Several of the species and forms of Rudbeckias possess a kind of rhizome, and are usually more or less evergreen. These creeping shoots root freely in their onward course, and thus afford ample means of increase. With the species under notice the rootstock is compact, very hard and brittle; the roots also are wiry.

I consider early spring the best time to increase *R. purpurea*,

just as the new leaves appear above the surface. To insure dividing the plants with as little loss as possible the soil should be shaken or washed from the roots, when the operator will better realise what he has to contend with. I find a small three-tined hand-fork much better than a knife for dividing them, as the pieces split off from the main root far more readily than it is possible to cut them. A direct cut right through the plant with a knife—assuming it possible to get the latter through—will result in much loss of root, and from this cause I abandoned its use some years ago in favour of the hand-fork, and can only recommend those who desire to increase their stock of this handsome plant to do likewise. In large plants the crowns are numerous, and many may be had with roots attached, which should be potted singly and placed in a cold frame kept close and shaded till new roots are formed, and when well established in the pots, which they should be in a month or six weeks, they may be planted in the border in groups, always in a conspicuous spot. Some plants, I find, are more woody in the rootstock, and have only a hard single stem. Such as these it is difficult to divide, but I detach the new breaks—i.e., growths with a heel, and insert as cuttings in the usual way, by which means I have this year obtained a small stock of plants. It is worthy of note that this still little known plant has a vigorous constitution and is self-supporting.—J. H. E.

SOME NOTES ON THE BARK OF FRUIT TREES.

THE bark of a stem bears an important part in the well-doing of a plant, and it is right that it should be protected from harm when necessity arises; but some instances which have come under my notice have given me the impression that even in this matter we may be over-zealous. A close observation will show us that while some stems, for instance those of an Apple tree, have a glossy appearance and some elasticity, other have a hard dull look which is anything but pleasing. The former is a sure sign—other respects being equal—of a satisfactory condition, while the latter is a plain proof that all is not as it should be. To remedy this latter condition some have recourse to the knife, and make a longitudinal incision the whole length of the stem. In some cases it is not necessary to go the whole length, but several cuts, according to its thickness, may be made with advantage. When this is done care ought to be taken not to go deeper than the thickness of the bark. I have known this treatment prove so satisfactory that I think it might be practised more frequently. When a plant is in this bark-bound condition it is worse than useless to keep feeding, or rather glutting the roots with manure, for the inability to absorb this nourishment causes the roots to perish, and thereby hastens the plant's decay. Rather ease the bark and feed carefully for a time, and it will soon return thanks for the treatment it has received.

An instance which proved to me the advantage of this treatment was a Peach tree which for years made stunted growth, and the few blossoms it showed fell prematurely without setting any fruit. As a last remedy three long cuts were made through the bark, and as each cut widened the tree improved in appearance, so that now fine crops of fruit are annually gathered. Since I saw this experiment I have proved that it is equally applicable to all fruit trees, and the results on those of a more ornamental nature have been most gratifying. I need hardly add that this in itself will not cure unfruitfulness, but whenever the stem is so hard that it will not yield to the firm pressure of the thumb, a cut through the bark will lead to better results than a top-dressing of manure. The Vine seems to have a natural aptitude for this bursting of the bark more than any other fruit tree, and the wider it bursts so much the more fruitful it becomes, and the better able to perfect the crop.

A still rougher example of this system was brought under my notice in an orchard into which some cows were turned out in early spring when the pasture was at its scantiest. They attacked the trees, large and small, lacerating the bark with their teeth, and rubbing themselves against the stems, so that in some places the wood was bared. Like many others I thought the last fruit had been gathered from those trees, but after the cows were removed the bark commenced healing over, and although some portions of the stem will never again have their natural covering, the trees have fruited the same as before. In some cases a decided improvement has been the result. This is not put forth with the dictum, "Go thou and do likewise," but to show how far this easing of the bark may be carried without fatal results.

A large Peach tree was for some time a puzzle to me. The main stem of the branch on one side of the tree must have had its bark rubbed off when young, and had never healed thoroughly, yet this branch always set a full crop of fruits which, though not large, were of fine colour and flavour. On the branch at the opposite side, which was the very picture of health, the fruits never set

freely, and yet the buds were always plump and promising. After seeing the orchard just mentioned, I cut a good slice of the bark clean away from the branch which was unfruitful, but being unused to such seemingly barbarous treatment, I cut it from the side nearest the wall where it would be less likely to be noticed. After this it fruited more freely than before, so that I had cause to be pleased with the experiment.—M. D.

PHLOX DRUMMONDI CUSPIDATA.

THE numerous beautiful varieties of *Phlox Drummondii* as grown in this country are proved favourites in hundreds of gardens, but those introduced from the Continent a short time since under the names of *cuspidata* and *fimbriata* are extremely distinct departures. One of these, which has been received at Kew and grown under the name of *Phlox cuspidata*, is shown in the woodcut (fig. 44), and is marked by the lobes of the corolla being prolonged into acute points. In some of the

FIG. 44.—PHLOX DRUMMONDI CUSPIDATA.

flowers these points are very long, and impart a star-like appearance to the flowers. The colours present a similar range to the ordinary *P. Drummondii*, but purple seems to predominate. The only appreciable difference between the varieties *cuspidata* and *fimbriata* is that in the latter the lobes are not so much prolonged and they are rather more irregular.

COMPENSATION FOR ORCHARD PLANTING.

BY MR. WILLIAM F. BEAR, STREATHAM.

IT is no doubt solely because of the great interest which, for many years, I have taken in compensation for tenants' improvements, that I have been invited by the Committee of this Conference to read a paper upon a subject of the practical details of which I probably know less than any person in this room. I must confess that I felt a strong disinclination to place my views before a body of experts, and if anyone but your worthy Secretary, who has been very obliging to me on more than

one occasion, had asked me to come forward, I should have declined. For should anyone ask me what I know about orchard planting, I should have to reply, Next to nothing. When I took a farm some years ago I planted some fruit trees, and had them in fine bearing condition by the time that I quitted the holding, to the advantage of my successor. More recently I have planted some Apples and Pears in a suburban garden, and have scarcely seen a blossom on any of them for the last three years. However, my subject is not planting, but compensation for planting, and upon that topic I have very decided views, and few persons, I believe, have given more thought to it. Still, as my object is to elicit discussion rather than to air my own opinions, I shall be as brief as possible in my remarks.

Cultivators of the soil are constantly being told that they should grow more fruit. Ordinary farming does not pay and is not likely to pay, it is contended, and farmers should turn their attention to the production of vegetables and fruit. Now there is no reason to fear that too many farmers will take that advice, the rank and file of the class being very slow to make any important changes in their routine. It is obvious that if even a twentieth part of the land of the United Kingdom were devoted to the growth of culinary vegetables and fruit, the market would be glutted unless the nation were converted to vegetarianism. But, as I have said, there is no reason to fear that too many farmers will become market gardeners and fruit growers, and there will be all the less reason to expect this if, as I believe, a turn in the tide of ordinary farming as a business has set in—whether for a long or for a short period it would be rash to predict. The fear is—to confine myself to fruit-growing—that, in spite of the “boom” which appears to have been started in that industry, its development will be slower than is desirable. There are many reasons why it should be so. Enough has been said in recent years, and said over and over again, to prove that it is desirable to grow more fruit, and especially more choice Apples and Pears, in this country. The question is, how to do it? Now, in my opinion, Mr. Rivers, in his speech as chairman of the Fruit Growers' Conference held the other day in the Crystal Palace, went the right way to work to show how not to do it. Alluding to the obstacles of fruit-growing, he is reported to have said that landlords, land laws, railway rates, and middlemen have nothing to do with them. A more astounding assertion I have seldom read. In my opinion they have pretty well all to do with them. It is our land laws which render fruit-planting an unsafe speculation, and high railway rates and a bad system of distribution (the middleman element) which render fruit-growing less profitable than it should be. I think my friend, Mr. Albert Bath, was on the right tack in the paper which he read at the first Crystal Palace Conference, and not Mr. Rivers, who declared ignorance to be the fundamental hindrance to extended fruit culture. No one is a more earnest advocate of agricultural and horticultural education than I am, and no one is less disposed to say anything to underrate the advantages of either branch of instruction. But, in my opinion, for one cultivator of the soil prevented from growing fruit by ignorance, there are twenty who are deterred from lack of security to capital invested in planting, high railway rates, which render it unprofitable to grow anything except high-priced early produce if it has to go a long distance by rail, and our abominable system of distribution, which gives more profit to the middleman for a day's, or sometimes for an hour's work, in handing fruit on to customers, than to the producer who spends a year in growing it.

Returning to the question, How is fruit-growing to be increased? I must pass by, as beyond the range of my subject, all details relating to such obstacles as high railway charges and the middleman's undue share in the amount paid by consumers for fruit. In considering how to answer the question asked, another at once crops up—Who is to plant? Now our land laws are directly opposed to planting, as far as they go. By encouraging limited ownership through the settlement of estates they render it disadvantageous to most landowners to plant, because the limited owners, who form the great majority of the landlord class, by sinking their capital in orchard planting, would reap only a transitory benefit themselves, and that only if they lived several years, while they would enrich the already too highly favoured heirs to their land at the expense of their younger children or other relatives. For reasons which it would take me very wide of my mark to-day to state, I am not in favour of increasing the powers and privileges of the owners of land by making them absolute owners, and I allude to limited ownership merely to show that under it there is no reason to expect extensive orchard planting by landlords. We come now to the tenants, and are thus brought within the precise confines of the subject of this paper.

Mr. Rivers appears to argue that the land laws have nothing to do with the indisposition of cultivators to plant fruit, because in suitable

situations and under proper management fruit-planting will pay with laws and rents as they are. No doubt it will, provided that the planter has a long lease and lives long enough to reap the fruits of his enterprise, or if—and this is a very large “if”—he can induce his landlord to consent to the planting, so that he will be entitled to compensation under the Agricultural Holdings Act, or to arrange otherwise to compensate him or his heirs when he quits his holding or dies. These “ifs” and “ors,” however, are shadowy particles, and a substantial and disagreeable “but” nearly always comes in to put them to flight. Without the consent of the landlord in writing the law fails to afford the fruit planter, whether he be a large farmer or an allotment holder, a halfpenny of compensation for capital sunk in the planting of fruit; and I doubt whether that consent can be obtained by one out of a hundred tenants. The tenant, then, has no legal security for fruit-planting, and if he plants without security he incurs a very serious risk. It may be contended, perhaps, that a long lease affords sufficient security, but that I entirely dispute, because a man may die before he has reaped any benefit from his expenditure, and it may be inconvenient for his executors to carry on his business, or he may be obliged to remove, either from getting into difficulties or from some less disagreeable cause. Therefore a lease is but a delusion as security unless it contains compensation clauses or embodies a right of assignment. Moreover, a lease never affords adequate security unless it is a very long one, even if the holder of it farms it out. Even then, at the end of the lease, the improving tenant—or rather, the law—hands over to the landlord property which rightly belongs to himself.

It is not necessary to say before my present audience that the expense of orchard planting is no light one, or to point out that some years must elapse before the planter can hope to obtain a satisfactory return on his outlay. Probably there is no gentleman here who could not tell me a great deal more about the cost of planting than I can tell him. But as there may be readers of this paper who are not experts, and who may like to have the estimates of experts on the cost of planting different kinds of fruit, I submit such estimates. There is no lack of them in print, but most of those in my possession are two, three, or more years old, and expenses vary with the times. I therefore asked Mr. Charles Whitehead to give me his estimates for the present time, and I have to thank him, a busy man—though for that matter, busy men are generally the most obliging in affording information—for kindly complying with my request. In giving Mr. Whitehead's estimates, I must point out that they do not include the cost of preparing the land, or any portion of the rent, tithe, rates, and labour expenses after planting which fall due before the trees come into profit.

COST OF PLANTING ONE ACRE OF FRUIT.

	£	s.	d.	£	s.	d.
Standard Apple trees, 22 feet apart (90 trees) ...	6	0	0			
Planting and staking ...	2	17	6			
				8	17	6
Plums or Damsons, 18 feet apart (134 trees)...	7	15	0			
Planting and staking ...	3	15	0			
				11	10	0
Apples and Plums mixed, 20 feet apart (108 trees)...	7	0	0			
Planting and staking ...	3	5	0			
				10	5	0
Bush fruit trees under Apples, 1440 to the acre, 5½ feet apart, at 13s. per 100 ...	9	0	0			
Planting bush trees ...	2	15	0			
90 Apples and planting and staking ...	8	17	6			
				20	12	6
Bush fruit with Plums or Damsons—1440 bush fruit trees ...	9	0	0			
Planting ditto ...	2	15	0			
134 Plum or Damson trees, and planting and staking ...	11	15	0			
				23	10	0
Strawberries 30 in. × 18=11,616 plants, say 12s. 6d. per 1000 ...	7	4	3			
Planting ...	1	15	0			
				8	19	3
Strawberries, 30 in. × 12=17,424 plants at 12s. 6d. ...	10	18	6			
Planting ...	2	7	6			
				13	6	0
Raspberries, in rows 4 feet apart, three plants to a hill or centre=10,890 plants ...	10	17	6			
Planting ...	2	5	0			
				13	2	6

Mr. Whitehead adds: “All these rates are according to present cost of fruit trees and present labour wages. The land, of course, must be deeply ploughed, and in many cases a subsoil plough should follow the ordinary plough. Harrowing also is necessary to get a level surface. Upon land in cultivation a good dressing of manure would be necessary, say 20 tons per acre. Some land would require trenching.”

Mr. Albert Bath, of Sevenoaks, has also kindly sent me some estimates, which represent the actual cost of planting now being carried out under his superintendence.

COST OF MANURING, PLOUGHING, SUBSOILING, TREES, AND PLANTING PER ACRE.

	£	s.	d.
Apple plantation, trees 20 feet × 20 feet apart	21	0	0
Plums, 20 feet × 20 feet	18	16	0
Pears, about same as Apples	21	0	0
Mixed plantation of Apples, Pears, Plums, 20 feet × 20 feet, with bottom fruit—Currants and Gooseberries	35	8	0
Raspberries (manuring and cultivation as above, excepting subsoiling)	17	5	0
Strawberries, ditto... ..	13	7	0

Mr. Bath remarks that fruit trees and Raspberry canes are as cheap as they were six years ago, but that Apple trees are in great demand, and will soon be dearer.

Although the planting of Strawberries and Raspberries does not come under the head of orchard planting, the estimates for these crops are allowed to appear in the list. I may add that Mr. William Vinson of Orpington, Kent, has kindly given his estimates of the cost of planting of an acre of these varieties of soft fruit. Including the first year's cultivation, rent, rates, &c., he says Raspberries cost about £15 an acre, and Strawberries about £10.

The veriest outsider must see from these figures—and especially from those relating to orchard planting—that it would be very risky for a tenant to engage in that enterprise without security as to compensation for the unexhausted value of his improvements; and it is to be borne in mind that Mr. Whitehead's totals should be larger than they are, because they do not include additional expenditure incurred while waiting for the trees and bushes to bear.

How, then, should compensation be given? Personally, I am a strong advocate of the plan of allowing the tenant to sell his improvements in the market, with pre-emption to the landlord. Elsewhere, and on many occasions, I have shown how I would safeguard the just claims of landlords in making the necessary arrangements for free sale. There is not time to allow of my going into details upon that topic to-day. Moreover, to do so would be needless repetition, for are they not written in the chronicles of the Farmers' Alliance—an Association which would have done great things for the farmers and fruit growers of the country if they had sufficiently supported it? In my opinion, free sale is far superior to the valuation system. When told that it involves dual ownership in land, I always say in reply, that where two persons invest their capital, and inextricably mix it in the same piece of land, you must have dual ownership or confiscation. There is absolutely no other alternative; and if you have a right to compensation by valuation, you have dual ownership just as much as if you have free sale. Again, I am told that free sale has not succeeded in Ireland; but the reply to that is that it was a splendid success in Ulster before Mr. Gladstone meddled with it, and, in my opinion, muddled it. Having visited Ulster, I say that the results of free sale there are wonderful. Considering the disadvantages in respect of situation, climate, and often of soil also, under which the farmers in that province laboured, what they did, stimulated by the security afforded to them by free sale, long before the Land Acts were passed, is a striking proof of the value of the principle.

It must be confessed, however, that free sale is not popular in this country. It may further be admitted that the system of compensation by arbitration and valuation can be carried out more satisfactorily in relation to fruit trees than in the case of ordinary farm improvements. The trees are on the ground, and can be counted and valued, and their condition indicates how they have been manured and otherwise treated. In some parts of Italy it is the practice to make an inventory of all the trees on a holding when the tenant enters, describing the number of trees of each kind in each enclosure, indicating the condition of the whole in general, if not of each, and valuing them. When the tenant quits a similar inventory is made, and he is entitled to receive, or required to pay, any difference in the two valuations, according to whether he has caused appreciation or deterioration during his tenancy. Whether or not any allowance is made for natural improvement on the one hand, or deterioration similar to the reasonable "wear and tear" in a house on the other, I cannot say. Perhaps some such plan could be adopted in this country.

The simplest reform, however—and I believe that fruit-growers and farmers can get it if they will but act together—would be that of striking out the stipulation in the Agricultural Holdings Act which requires the landlord's consent to entitle the tenant to compensation for planting fruit trees and for other permanent improvements. But as I

have always been a friend—an unappreciated friend—to landlords, I must state one objection to this proposal. It would be hard to come down upon a poor, embarrassed landlord, or upon one fairly well to do, but only a tenant for life, for £20 an acre or more on 100 or 200 acres, in the form of compensation to an outgoing tenant. Therefore, it seems to me that if the tenant is to be entitled to compensation for costly improvements made without his landlord's consent, the latter should have the option of presenting the right of free sale to the former. Or, perhaps, as landlords have always opposed free sale, it will be but a fitting lesson to them to make the amendment in the Agricultural Holdings Act just suggested, and to leave them to sue for free sale, which I fancy, under the altered circumstances, many of them would very quickly demand. At any rate, in one way or another, I contend, it is the right and the duty of the public to insist that the law of the land shall be so altered as to encourage, instead of hindering, the greatest possible development of the resources of the soil. They should not recognise the right of a man who is allowed to "hold an estate in land"—the nearest approach to absolute ownership recognised by the law of this country—to keep it as a desert waste, or anything like a desert waste, if it will pay for improvement, and there are capitalists able and willing to improve it. Or, to limit the application of this principle of public right and duty to the subject before us, I say that the people of this country, desirous as they are to see planting increased, should insist on their representatives in Parliament, without unnecessary delay, so amending or adding to the statutes as to afford to every cultivator of the soil full security for the unexhausted value of any improvement in the planting and culture of fruit which he is able and willing to carry out.

THE GARDENERS' ORPHAN FUND.—Some friends, thinking the Apple and Pear Conference last week favourable for doing something on behalf of this charity, organised a concert under the auspices of the Chiswick Gardeners' Mutual Improvement Society. This was held in the Vestry Hall on the evening of the 19th inst., and the visitors were well satisfied with the musical treat afforded and the beautiful floral decorations of Messrs. Roberts, Hudson, May, and Fromow & Sons. Mr. A. Dean was the chairman of the evening, but his efforts were quite unavailing to prevent encores. Mr. J. Barry distinguished himself by a recitation, and the chairman of the Fund, Mr. G. Deal, explained its origin and working with great lucidity, and said if £7 or £8 could be obtained at such an enjoyable meeting, the sum would afford support to a needy child for half a year. He commended the example of the Chiswick friends to others who might possibly help in a similar manner, and at the same time provide pleasant evenings' entertainments during the winter months. We are informed the suggestion is being considered by Messrs. G. Cannan and J. Dixon, managers of two of the branches of the extensive nurseries of Messrs. Lee & Son, Hammersmith.

— THE NOTTINGHAM HORTICULTURAL AND BOTANICAL SOCIETY.—A Chrysanthemum, Fruit, and Potato Show is announced to be held on Wednesday and Thursday, November 21st and 22nd, at the Arboretum Rooms, Nottingham. The prizes offered by Mr. R. Sankey, Bulwell, for the best essay "On the Duty of the Employer to his Gardener" will be divided as follows:—First prize, 20s.; second prize, 15s.; third prize, 10s.; which will be accompanied by the first, second, and third class certificate of the Society. The essay must not exceed fifteen minutes in reading. It will be read by a competent person, who will be appointed by the Committee, and must be sent to the Secretary, sealed up, and with a number or motto, but not the owner's name, not later than Monday, December 9th. The competition is open to all the members of the Society, and the papers will be read at the meeting on Wednesday, December 12th, 1888, at 7.30 P.M.

— MR. WM. KERL of Angmering, Worthing, writes:—"Last year I gave an account of GRAFTING APPLES UPON PEAR TREES. This year I have continued the experiment, and have grafted twenty-six scions of good Apples upon such Pear trees that were unfruitful or bore worthless Pears. Twenty-one have taken with strong shoots. The Apples I send were from the Pear tree I mentioned last year. In the neighbourhood of St. Albans they are called 'Worsted Stockings,' and

are very sweet and good up to Christmas. In the 'Fruit Manual' the nearest approach to them is the Aromatic Russet, or Spice Apple, and Morris's Nonpareil Russet. Will you kindly inform me in your Journal if they are one of these or have they any other name?" The variety sent is Morris' Nonpareil Russet.

— GARDENING APPOINTMENTS. — Mr. W. K. Woodcock has resigned the charge of the gardens of Mrs. Firth at Oakbrook, and Mr. John Pentland, late gardener to Miss Glyn, has been appointed his successor. Mr. Woodcock has taken the Syston Nurseries, near Leicester, and enters upon them on the 1st of November. Mr. Woodcock carries with him the good wishes of his numerous friends in Sheffield and other parts of the country, and heartily desires for his future prosperity and success. Mr. John H. Bowden asks us to notify his appointment as head gardener to W. G. Spicer, Esq., Oakwood, Camden Wood, Chislehurst, Kent. Mr. W. Smith has succeeded Mr. Wm. Hewett as gardener at Oakleigh, Merstham, Surrey.

— THE Mercers' Company, one of the oldest and wealthiest of the City Companies, is thinking of establishing an AGRICULTURAL COLLEGE. A correspondent of the *Times* says it proposes to devote £60,000 to this object. According to the same authority, the intention is that the College shall be in Wiltshire, and that there shall be attached a farm of considerable extent, in which the pupils may practically apply the knowledge they gain, the institution being intended to benefit the sons of farmers and others who will be dependent on the successful culture of land for their future livelihood. The sum of £60,000 contributed by the Company would, it is hoped, be supplemented by a liberal donation from the Charity Commissioners, and the Company would of necessity be prepared to provide an adequate endowment. An establishment of this kind with such substantial pecuniary support might be rendered a most important and valuable institution.

— Mr. C. OSMAN writes:—"The 8 acres of POTATOES referred to in my note on page 332 are now lifted, and there is a capital crop of Red-skin Flourball. None is diseased; of Reading Giant, Reading Hero, and Magnum Bonum very few. Imperator was rather more affected, about 1½ bushel diseased from several tons. Altogether the results were very satisfactory."

— CULZEAN ONIONS.—Mr. David Murray, the grower of the magnificent Onions referred to on page 336 as exhibited at Banbury, writes:—"The Onions were grown with Thomson's Vine manure. I always turn up the Onion ground into ridges. In spring before we start to level them down for the seed, we give the ridges a good dressing with the manure, and again when the Onions commence to bulb. That is the treatment that they had this year. I sprinkled a good dressing amongst the bulbs and watered it in. I was anxious to grow six to the stone (14 lbs.), but I was beaten by an ounce, but if well I will have another try." We hope Mr. Murray will accomplish his desire next year. It will be remembered the largest of the Onions referred to was 18 inches in circumference, and only an ounce less than 2½ lbs. in weight.

— THE WEATHER IN NORTH YORKSHIRE.—The weather in this district was very severe in the first week of October. On the morning of the 1st inst. 6° of frost were registered. Snow fell heavily from 8 A.M. till noon, the afternoon turned out fine. On October 2nd we had 13° of frost, which played sad havoc in the kitchen garden and flower garden. Dwarf and runner Beans were cut down. Broccoli has much the same appearance as it would have in March, with the exception of Purple Sprouting, which is unhurt. Celery leaves are turned brown. Walcheren Cauliflower is not hurt in the least. All bedding plants were killed to the ground. Herbaceous plants also suffered much. Amongst shrubs the Aucuba has fared the worst, the young growths are black, and the young shoots of the common Laurel are also badly affected. Farmers in the neighbourhood have sustained a serious loss, as few of them had gathered their Apples or Damsons; both are completely spoiled. The latter were sold in Kendal Market a week ago at prices ranging from 9d. to 1s. 6d. per hamper of 20 lbs. Even the Hazel Nuts in the woods are not eatable, the kernels are quite soft. During the week we had a total of 52° of frost.—C. RUSSELL, *Inquire Hall Gardens*.

— IN a recent number of a medical serial the free use of FRESH RIPE FRUIT as an article of diet is strongly recommended. Apples, Pears, Plums, Apricots, Peaches, Gooseberries, and Grapes are spoken of as being at the very summit of excellence as human food, for they possess the essential conditions of pleasantness, digestibility, nutrition, and medicinal value. With respect to Apples a late learned professor recommended every family to lay in a stock in the autumn, saying it

would be the most economical investment they could make. "A raw mellow Apple is digested in an hour and a half, while boiled Cabbage requires five hours; and if taken at breakfast with coarse bread and without meat of any kind fruit has an admirable effect on the general system, often rendering medicine quite unnecessary. It seems universally agreed that, as a community, we do not eat nearly so much fruit as we ought to do. Some authorities say that if the consumption was increased tenfold it would not be too large. There is no doubt that a really cheap and abundant fruit supply would mean a great improvement in the national diet, with a corresponding effect upon the health of the community, so that it is desirable on all accounts that owners and occupiers of land should bestir themselves and make the orchards of the country an increasing source of wealth, and fruit-growing a great national industry.

— THE VALUE OF CALIFORNIA FRUIT LANDS.—The question of land value in California is one which, in the fruit region at least, is open to discussion from various standpoints. A Redlands correspondent of the "American Garden" says:—"There are numerous instances of enormous profits from Oranges, yet if I were asked to say to an inquirer what a man may count upon I would figure 200 dollars to 300 dollars an acre. Orange growers are like all other farmers—one will get double out of an acre what another will. The Orange requires assiduous and intelligent culture for big results. Then it is quite the custom to suppress certain facts and enlarge on others. Here is a sample: A man had a prodigious crop of raisin Grapes—seems to me thirty tons or so on two acres. A raisin grower in another town could not believe it and went to see. The fact was as stated, but there were eighty acres in all cultivated without irrigation. The two acres were a sort of sink hole, very wet, and produced three times as many Grapes as the other seventy-eight acres. How did the crop average? That was not published, but very few keep accurate accounts. A Grape grower told me that, in response to circulars sent out by the Redlands Board of Trade asking for statement of expenses and results of various crop cultures, his was the only one sent back with accurate details. His figures on Muscat Raisin Grapes gave him 130 dollars per acre, the first decent crop. The second crop was 160 dollars, and this year he hopes to do better, and his is a fine vineyard. He represents the conservative side of these fruit yarns."

NOTES ON TOMATOES.

TOMATOES are rapidly becoming everybody's favourites. A medical man remarked to me the other day that they were bidding fair to become as generally used as Potatoes. There is no doubt that they are coming rapidly to the fore as an article of diet, and the more they become known the greater will be the demand, which the supply at present does not equal. Outdoor crops this year in most places have been a failure, consequently they are higher in price, and on that account can hardly be said to be within the working man's reach except as a luxury. If they could be grown and made to pay at 4d. per lb. there would be plenty of buyers. Disease is said to have attacked them badly in some districts this year. It is still unknown to us, and I have no desire to make its acquaintance.

We do not attempt growing them out of doors here in this cold wet district of Lancashire, but can obtain fair crops under glass which if marketed would pay at say 6d. per lb. wholesale price. This year we have grown nine varieties, and a few remarks on their merits may not be out of place. Sutton's Earliest of All was our first crop and kept in bearing from April to June inclusive. The flavour is good, and it is a free setter. Vicks' Criterion is a good cropping variety, smooth and even in size, of good flavour, and well worth growing. Webb's Sensation is another good sort; the colour of the fruit is much the same as Criterion, but the fruits are round and larger than that. Last year this variety grown at Chiswick was reported to be the same as Large Red. I have grown the two side by side, and find they are quite distinct. It is a more handsome fruit than Large Red. Hathaway's Excelsior we have grown for some years, and class it among the best of Tomatoes. The fruits set well this summer considering the dull sunless days. Trophy is an old variety that I should not grow again. It attains a large size, but it is so coarse and ugly that it is not worth a place. Golden Queen we have grown for the first time this year and like it well. The flavour is not quite so good, perhaps, as some of the others, but it is a good cropper with pale yellow smooth fruit, and is liked at the table mixed with others. Hackwood Park is a first-rate variety, and has succeeded the best of any here. It has set and cropped heavily, many of the fruits weighing half a pound and some over. We have still a number of fruits hanging that will keep for some time to come.

Queen is one of the small plum-shaped varieties that I consider well worthy of a place in any collection. It is a heavy cropping variety, and when ripe is very attractive. It is also a first-rate flavour and does well for mixing with salad without being cut up. I observed a week or two ago Mr. Iggulden was condemning the small varieties as not worth growing and not nearly so good in quality as the larger growing sorts. I send herewith a few fruits of Queen, and perhaps you will kindly give your opinion as to quality. In my opinion it is the best flavoured of all I have named. I readily admit it would not be so profitable to grow for market, but for home use I think a few plants worth a place.—G. HILTON.

[Our opinion was given in answers to correspondents last week, before this communication was read. We stated the variety was Nesbit's Victoria or a selection from it. A few plants are well worth growing in private gardens.]

HINTS TO INTENDING EXHIBITORS.

THE following remarks are intended mainly for those who purpose becoming exhibitors for the first time at some of the coming shows. The greatest mistake made by exhibitors is that of attempting to do too much at once—that is going to too many shows in one season, and entering and staging in too many classes at one date. Much better would it be if exhibitors contented themselves with fewer classes, which they might fill far more creditably to themselves as well as to the credit of the exhibition. Of course if the means—a sufficient number of blooms—are at hand to fill many classes at one show, so much the better, as the expense of taking a lot is not much more than taking a few. "A name" is much more easily made by "sweeping the decks" at one show than by competing at several places in one or two classes and possibly taking second and third prizes in many instances. See that the entries are carefully made on the proper forms accompanying the schedules and punctually sent in to the Secretary. If possible send in the entry two or three days before the appointed time, as this is of assistance to the officials in preparing the necessary cards and positions. Attend early to procuring suitable stands, boxes, cups and tubes, tweezers and proper labels, on which the names should be plainly written. The work of arranging the blooms in the stands must of necessity be tedious and often perplexing to the beginner, but by studying closely the information given by others the work is simplified.

It is a good plan to practise on blooms that are useless for exhibition, or upon such that are not needed for competition. The right method of staging is much more easily obtained by practice combined with studying other people's ways. Dressing blooms of the incurved section requires much practice and patience before efficiency is gained. Dressing the blooms consists in arranging the petals in a straight, even, smooth manner, removing damaged or imperfect florets, filling up the centre of each flower by cupping them sufficiently tight with the tube placed under the bottom row of florets. When many blooms have to be cut and staged some method must be employed to properly carry out the work. The best plan is to note the varieties available. Selections can be made from this list of varieties that are best suited for the back, middle, and front rows, so as to insure uniformity throughout the stand. The largest blooms should be placed at the back, and so on in proportion. If the list be marked with figures 1, 2, and 3, indicating the blooms that are intended for each row in the stand, the work of staging will be facilitated considerably. A glance at the list suffices to show the position each variety will occupy in the stand. An early start should be made in preparing the blooms, so that the work be not hurried at the last moment. Packing the stands in the boxes should be performed carefully, or some damage may be done to some of the blooms during transit, such as one flower chafing against its neighbour when they are placed in the stands in a loose manner. Prizes have often been lost through faulty packing.—E. MOLYNEUX.

CHRYSANTHEMUMS IN IRELAND.

I FIND that in this locality most of the growers complain that their plants are likely to come into bloom much later than last year, particularly those grown as specimen plants. The plants grown to produce large show blooms are also rather backward. Some growers fear they will not be ready in time for our local show, to be held on November 13th. It is also noticed in most of the collections that damp is seriously affecting the blooms which are now opening, particularly white and pink varieties. I should like to know what reports growers in other localities have to give.—THOMAS PHELAN, *Clonmel*.

CHRYSANTHEMUMS IN STAFFORDSHIRE.

FROSTS are of nightly occurrence here accompanied by dense fogs. My plants were caught in the frost three weeks ago, but were not very much damaged. Peter the Great suffered the worst, and the

Japanese collectively more so than the incurves. A new exhibitor has arisen in Staffordshire, but I must not divulge his name yet. He will commence his career this season all being well, but he will make it "hot" for somebody next year. He has 1000 capital plants for large flowers, but is short of incurved varieties—plenty of plants.—A GROWER.

CHRYSANTHEMUM TUBES.

FIG. 45.—CHRYSANTHEMUM TUBES.

IN the woodcut (fig. 45) some convenient Chrysanthemum tubes are represented, each being furnished with two springs at the base of the tube by which it can be steadied in the water tube and fixed at any requisite height. We understand that they have been invented and patented by Mr. Lindsay of Otterspool Gardens, Liverpool, who is well known as an accomplished stager; and, as advertised last week, they are being supplied by Messrs. Cannell and Sons of Swanley.

NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the Floral Committee was held in the Royal Aquarium on Wednesday last, October 24th, when numerous novelties were exhibited. The members present were E. Sanderson, Esq., in the chair, and Messrs. W. Holmes, G. Gordon, Lewis Castle, H. Cannell, C. Gibson, Bevan, R. Owen, Stevens, Mardlin, C. Swift, J. P. Kendall, R. Dean, and S. Gilbey.

Certificates were awarded for Sunflower (Japanese) and Nelson Japanese Anemone from Mr. W. Holmes; Violet Tomlin, an incurved sport from Princess of Wales, much darker in colour, from Mr. Doughty, Angley Park Gardens, Cranbrook, Kent; Magieienne (Owen), a Japanese; H. Shoemith (Davis & Jones), incurved, a beautiful bronze sport from Mr. Bunn; and Stanstead Surprise (Laing) a large Japanese with long rosy crimson florets and lighter reverse, very handsome and distinct. Commendations and vote of thanks were also awarded for several varieties from Messrs. J. Veitch & Sons, W. & G. Drover, W. K. Woodecock, R. Owen, G. Stevens, W. Piercy, and W. Holmes. The best of the varieties thus recognised were May Tomlin, a sport from Mdle. Dutour, Lincoln Inn, and Sam Henshaw.

AT CAMBERWELL.

THE interest in Chrysanthemums is rapidly re-awakening, and those devoted to showing and growing, both amateurs and professionals, are preparing for a busy season. Inquiries are being made respecting neighbours' and possible rival competitors' collections, and the nurseries are attracting their usual visitors, who are desirous of learning what promising new varieties may be worthy of notice, what recent introductions maintain their characters, and what old varieties still keep their places as indispensable. Owing to its proximity to railway stations, its short distance from the city, and the fact that Chrysanthemums constitute the exclusive specialty, the Lilford Road Nurseries, Camberwell, is usually selected as one of the establishments to be inspected, and Messrs. Davis & Jones always succeed in rendering their collection well worthy of a visit. This season seven houses are devoted to Chrysanthemums, ranging in size from small compact span-roof structures to the spacious show house, 65 feet long by 30 feet wide, and proportionately lofty. Some of the houses have been occupied with plants grown for cutting, such useful varieties as Roi des Précoces and Lady Selborne having prominent attention. The former is an excellent early and free flowering Chrysanthemum, the light graceful blooms of a rich crimson hue, quite distinct and capital for arranging in vases or stands. It makes a good companion for Madame Desgranges, yielding an astonishing number of blooms, and its value has been already well proved as a market plant.

The collection comprises all the leading varieties in the different sections, together with most of the continental and American novelties. The incurved are promising well, and Mr. Davis ventures on a prophecy that these varieties will be found more generally satisfactory than usual, perhaps because a cool damp summer is less trying to the plants than an excessively hot and dry one. Certainly substantial buds and blooms are expanding steadily but freely, the "Queen family," the "Dixons," "Rundles," and "Glennys" looking capitally, while of the later varieties Princess Teck and Charles Gibson are in strong force and excellent condition. Of Mr. Bunn there are numerous fine blooms; but the most notable in this section is a bronze sport from Mr. Bunn named H. Shoemith, which, while possessing all the chief characteristics of its parent in style of bloom and habit, is distinguished by its bright bronzy orange hue. It appears to be well proved and fixed, and for the earlier shows, where Mr. Bunn can be shown to advantage, this will be found useful as a companion. Beverley, Golden Beverley, Mr. Bunn, and H. Shoemith now form quite a family in the same way that Princess of Teck, Hero of Stoke Newington, and Charles Gibson constitute a family type. With regard to the incurved, it might be added that Bronze Queen appears to be developing much better blooms than it has done before, and judging by those at Camberwell it may yet become a favourite exhibition variety.

The Japanese are as usual very numerous, and some most interesting comparative trials of new varieties have been carried out, with the result that unquestionable identity has been established between several

of the recent Japanese introduced to this country from Japan and *via* America. Concerning these there will be much to be said by-and-by, for the matter is an important one, and it is rather serious to find varieties obtained from several different sources under distinct names prove to be identical. Very beautiful is Florence Percy at the present time, its quilled and twisted pure white florets imparting quite a lace-like appearance to the blooms. Priscilla is one of last year's Japanese with bronzy red or cinnamon blooms, of long irregularly cut and twisted florets with a yellow reverse. Edwin Molyneux, C. Orchard, and Belle Paule are showing well, as also are Edouard Audiguier and its beautiful golden counterpart, M. Garnar. A pretty variety of the Japanese reflex style, Dr. Dor, is worthy a note, the florets fluted, recurving, and bronzy buff, a very distinct shade of colour. Many others might be mentioned, but the above will suffice to show that the interest of the Camberwell collection is fully equal to that has possessed in past seasons.

AT CHILWELL.

JUDGING from the appearance of the plants in the well-known nurseries of Messrs. J. & R. Pearson & Sons, the display of Chrysanthemums there is likely to be one of the most extensive in the kingdom. The exhibition was fine last year, and admired by thousands of visitors from Nottingham and surrounding district, while not a few persons journeyed long distances to the great Midland show and went away satisfied. The plants are still finer this year, and more numerous. Six large houses are filled with them, but the chief display is represented in a light and lofty span-roofed structure 100 feet by 30 feet. The plants are arranged down the centre and along both sides. The varieties that produce the finest blooms are disbudded for producing them, and as they are strong, with handsome foliage and ripe wood, some superior examples may be expected. Edwin Molyneux is fine now, as are a few others, but the time has not arrived for particularising varieties. Those which are essentially free in flowering are grown in large bushes and not disbudded, so that their character for decorative purposes is displayed, and their capacity for producing trusses for cutting represented. A few well-trained specimen plants are also included, as are small plants in 5 and 6-inch pots for table and window decoration. The collection, which includes all the best varieties, old and new, is indeed a typical one, and such as Mr. Charles E. Pearson and his assistant may be proud of. Many persons travel far to see what is to be seen in the Chrysanthemum world, and if possible they should not omit Chilwell when the plants are about their best, in November. It is within a mile from Beeston station, which is reached from Nottingham in seven or eight minutes.

AT MORDEN PARK.

THE Chrysanthemums at the residence of J. Wormald, Esq., Morden Park, Surrey, have for some years constituted an important specialty under Mr. C. Gibson's charge, and many honours have been won in keen competition at the leading metropolitan and suburban shows. This season over 400 plants are grown, and they look extremely well, indeed Mr. Gibson thinks he has never had the plants in better condition. Blooms also are coming freely, but possibly some of these are rather too early for the show season, though there will still be plenty left to win some prizes. It is rather strange, however, that when so many are complaining of the lateness of their blooms the Morden Park collection should be so forward, and it is a disadvantage, because it is found that blooms are not keeping well, the lower florets failing before the bloom in some cases is half developed. Probably the fogs and heavy mists have had some effect in this direction. The incurved varieties are very satisfactory, and fine examples are noted of Mrs. Shipman, Princess Beatrice, and the Queen type, the last named being uncommonly good. Of Japanese, Edwin Molyneux is grandly represented, also C. Orchard, Criterion, Phœbus, Peter the Great, Boule d'Or, Mrs. Cannell, Mr. Garnar, White Dragon, and Avalanche. One of the varieties in the Japanese with which Mr. Gibson excels is Grandiflorum, though this disappoints many growers, and it is thought the cause of this is to be found in taking the crown instead of the terminal bud. At any rate Mr. Gibson relies exclusively upon the terminal bud, and never fails in obtaining good blooms, and the earlier this bud can be "taken" the more chance there is of the blooms coming in for the shows. Lady Trevor Lawrence and Mrs. H. Cannell have been found to be identical here, though received from a reliable source, and as we hear the same complaint elsewhere it is evident there is some confusion, and exhibitors will do well to carefully ascertain that varieties under these names are really distinct before placing them in one stand, or they may run the risk of disqualification. It is not questioned that the varieties first exhibited as Lady Trevor Lawrence and Mrs. Cannell were distinct, but it is quite clear that there has been some mistake since, and it is difficult to ascertain where the blame rests. Mr. Gibson has a good general collection of Japanese, Anemones, reflexed and all the other sections provided for at shows, and we shall hope to see some of his productions at distant exhibitions before the season is over.

AT WARREN HOUSE GARDENS.

THE genial Honorary Secretary of the Kingston Chrysanthemum Society, Mr. Woodgate, amidst the multifarious duties attendant on an extensive charge, manages to grow some 400 Chrysanthemums, and to produce blooms of high exhibition quality. This year his plants are in very satisfactory condition, slightly late, but the buds are expanding "kindly," and a large proportion may be expected to reach full exhibition size and quality, though perhaps somewhat late for the principal metropolitan shows. Taking the majority of the plants, there is quite a

fortnight's difference between the Morden Park and Warren House plants, though the gardens are situated only a few miles apart in the same county. The collection comprises, beside the standard old varieties, a good number of the recent introductions and novelties, but it is somewhat early to pronounce respecting their merits. One point is noticeable—namely, that Mr. Woodgate has not attempted to restrict the naturally tall-growing varieties, for some plants are 9 and 10 feet high, but after rather nervously climbing a ladder and inspecting their summits, we found what is very often found on these giants, very substantial, fat, and promising buds of prize-winning capabilities.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 23RD.

A SMALL space in the Drill Hall at Westminster sufficed for the exhibits on Tuesday last, Chrysanthemum blooms and a few new plants being all that was shown of any consequence.

FRUIT COMMITTEE.—Present: H. J. Veitch, Esq., in the chair, and Messrs. P. Crowley, G. W. Cummins, R. D. Blackmore, J. Willard, J. Smith, W. Denning, J. Cheal, P. Barr, and W. Marshall.

Mr. Crook, Farnborough Grange, exhibited fifteen dishes of Apples, Pears, and Plums, including some fine fruits of Blenheim Pippin and Alfriston Apples, Duchesse d'Angoulême, Doyenné du Comice, and Pitmaston Duchess Pears. The Pears were from trees trained to walls, and all indicated good culture (vote of thanks). Messrs. J. Carter and Co., High Holborn, showed a basket of Stachys tuberifera tubers, and the Committee requested that specimens be sent for cooking to be tested at the next meeting. Mr. Smythe, The Gardens, Basing Park, Alton, sent two varieties of black Grapes, one of which the Committee desires to see again. Mr. Smith, Mentmore Gardens, Leighton Buzzard, showed specimens of Prune, Worcestershire, Shropshire, or Cheshire and Farleigh or Crittenden Damsons. Captain Ferry, The Shrublands, Hersham, Walton-on-Thames, exhibited a dish of Duchess's Favourite Apples very highly coloured (vote of thanks).

From the Royal Gardens, Kew, came fruits of the Tree Tomato (*Cyphomandra betacea*), like small Egg Fruits, of a deep red, and *Trichosanthes anguina*, (the Snake Gourd), with long narrow bright red fruits. Mr. A. Selby, Radcliff-on-Trent, Notts, exhibited fine tubers of Sutton's Abundance, Reading Giant, and Satisfaction Potatoes (vote of thanks). Mr. W. Ellington, Mildenhall, Suffolk, sent tubers of a new Potato named Market Favourite, a seedling from Vicar of Laleham crossed with Schoolmaster, white, with a purple tinge and eyes. It is to be tried at Chiswick.

FLORAL COMMITTEE.—Present: G. F. Wilson, Esq., F.R.S., in the chair, and Messrs. Shirley Hibberd, W. Goldring, H. Herbst, J. Bates, W. Holmes, R. Dean, C. Pilcher, J. Dominy, H. Ballantine, H. M. Pollett, J. O'Brien, W. Wilks, E. Hill, T. Baines, G. Duffield, and John Fraser.

Mr. W. Holmes, Hackney, sent a stand of new Chrysanthemums comprising M. C. Sachet and Sunflower, certificated as Japanese, a distinct Japanese Anemone named Nelson of a deep purplish crimson colour, and broad recurving guard florets, and a yellow variety of the same type named Sabine. Mr. Holmes also had two baskets of October-flowering Chrysanthemums, Feu de Bengale being awarded a vote of thanks. Mr. G. Stevens, Putney, showed blooms of the pure white Japanese C. Wagstaff (vote of thanks). Messrs. J. R. Pearson & Son, Chilwell, were awarded a vote of thanks for several blooms of Chrysanthemums, mostly Japanese, including Othello, C. Delmas, Charlotte de Montcabrier, Madame Louise Leroy, and Capucine, a new October-flowering variety with bright orange yellow blooms freely produced, which was commended as an early decorative variety. Mr. R. Owen, Maidenhead, exhibited a stand of eight new Japanese varieties, for two of which first-class certificates were awarded. The others were Comte Horace de Choiseul, white; Miss Burgess, quilled, rosy mauve; Thomas Stevens, bluish, drooping; Madame C. Souchet, straight purplish florets, tipped white; M. C. Souchet, reddish, recurving, reverse golden; and Bocace, single, purple and white. Mr. H. Jackson, gardener to S. A. Ralli, Esq., Cleveland House, Thornton Road, Clapham Park, sent a branch of *Lapageria alba* bearing, on a length of about 9 inches, fifteen bluish-tinted flowers (vote of thanks).

Messrs. J. Veitch & Sons, Chelsea, exhibited several novelties, comprising *Alocasia Chantrieri* with metallic-like leaves and silver veins, *Rhododendron Brunette*, a cross from *R. javanicum* and *Princess Frederica*, with large buff flowers having six or seven segments (vote of thanks). G. F. Wilson, Esq., F.R.S., Weybridge, showed flowers of the double *Colchicum* which had stood the frost, and flowers of a white *Primula capitata*. J. A. Whittard, Esq., Rydal Mount, Streatham Hill (gardener Mr. H. Wright) sent a sporeling form somewhat of the *Adiantum cuneatum* style with small pinnules, strong but graceful (vote of thanks). G. H. Baxter, Esq., Hutton Park, Brentwood (gardener Mr. E. Crook) exhibited a plant of *Odontoglossum Insleayi splendens* of very rich colour (vote of thanks). Messrs. Seeger & Tropp, East Dulwich, showed a plant of *Cypripedium Scgerianum*, described as a hybrid between *C. Spiccranium* and *C. Harrisianum*, the dorsal sepal white, tinged purple at the base (vote of thanks).

CERTIFICATED PLANTS.

Cattleya Harrisii (Baron Schröder).—A cross between *C. Mendeli* and *C. Leopoldi*, a most beautiful production and presenting an interesting combination of the characters distinguishing the two species named. The sepals and petals are of semi-transparent texture faintly but

evenly suffused with purple, the lip having a central rich crimson lobe, the side lobes white tipped crimson. Powerfully fragrant.

Cattleya Lamberhurst Hybrid (Baron Schröder).—A cross between *C. intermedia* and *C. citrina*, one of the most interesting hybrids yet obtained; the flowers drooping with narrow sepals and petals, white, faintly bluish tinted, the lip with a narrow tube and central purplish lobe, very fragrant. The pseudo-bulbs are somewhat like *C. citrina*, but more elongated, and bearing the flowers at the apex. Very fragrant, but distinct from *C. citrina*.

Oncidium Mantini (J. Veitch & Sons and G. H. Baxter, Esq., Hutton Park, Brentwood).—A supposed natural hybrid between *O. Forbesi* and *O. Marshallianum*; the flowers of good size and shape, the sepals and petals reddish brown on yellow, the lip broad, spotted brown on yellow.

Rhododendron Yellow Perfection (J. Veitch & Sons).—A cross between *R. Teysmanni* and *R. Lord Wolseley*, the flowers 3 inches in diameter, the lobes round and broad.

Chrysanthemum Sunflower (W. Holmes).—A Japanese variety of great merit; the blooms large, the florets long and drooping in the way of *Belle Paule*, but of a rich golden hue.

Chrysanthemum Lincoln's Inn (W. Holmes and R. Owen).—A medium-sized Japanese variety, with reddish fluted drooping or recurving florets, a bright colour, and distinct.

Chrysanthemum Magievene (R. Owen).—A handsome Japanese with large blooms, slightly recurving florets, of a bronzy red or bright cinnamon hue.

Chrysanthemum Edwin Molynæus (G. Stevens).—This variety is now too well known to need description. It was certificated last year by the National Chrysanthemum Society.

BRIAR v. MANETTI.

IN the revived dispute of "Briar v. Manetti" I have no intention of taking a share, inasmuch as it must be settled by those who have more varied experience than I, who have never had to deal with any soil but a very stiff clay, where Roses on Briar will, as a rule, live and thrive well, and on Manetti are but ephemeral. But out of this another question arises. I find that sundry varieties, and among them some of the best, notably Marie Baumann, A. K. Williams, and Reynolds Hole, which will not thrive permanently even on the Briar, but die off or go back in two or three years, leaving unsightly gaps in the rows, a matter of some importance to those who wish to keep down the nurseryman's bill, and who do not find it quite so easy to bud dwarfs as it was twenty or thirty years ago.

There may, however, be a stock not yet developed on which these, and others like them, will permanently thrive. At present 99 per cent. of Roses are budded on the two orthodox stocks, and the other 1 per cent. on *Griffaria* or other fancy stocks. It is much to be wished that some one with time and space to spare would experimentalise on various new stocks and give the world the result of his experience. It seems, for instance, as if John Hopper would be a good stock, strong, clean-growing, and not much given to send out base shoots. I would try it myself if I had the Rose on its own roots.

One more question I would suggest for discussion in your columns. Has not the time come for a formal divorce in Rose shows between H.P.'s and Teas? They used to be shown together, then the Teas got classes to themselves, and were still allowed to be shown in conjunction with H.P.'s in the general classes. I think myself that they ought now to be relegated to their own special classes and the others have their own boxes to themselves. However beautiful they may be, and no one can admire them more truly than myself, they seem to me, from their very delicacy of colour, out of place among the bolder and more masculine (so to speak) varieties, and we have now a sufficient number of light-coloured Roses among the latter to break the uniformity of reds to which we had to submit some twenty years ago, unless we put in a certain number of varieties inferior in other respects for the sake of lightening up the general effect.—DUCKWING.

ROSE CULTURE.

[By Mr. T. Bones, gardener, Tower House, Chiswick, winner of first prize for an essay on some gardening subject. Prizes offered by Mrs. S. A. Lee, 4, Arlington Park Villas, Chiswick, for competition by members of the Chiswick Gardeners' Mutual Improvement Association, under the age of thirty.]

IN selecting a subject I think I cannot do better than give a few practical remarks on the cultivation of the queen of our gardens—the Rose, which justly deserves this proud distinction.

In Rose-growing we have two very important points to consider—namely, soil and situation. The Rose succeeds best in a rich loamy soil of a rather stiff nature, free from stagnant moisture, as it will not flourish long if the ground is badly drained. If draining is required it should be done by laying pipes about 3 feet deep. If the soil is light it may be improved by adding some very stiff loam and night soil that has lain in a heap at least six months, and has had a turning occasionally. This should be worked in when the trenching is done, keeping it well

under the surface, as it is injurious to the roots of newly planted trees; if night soil cannot be had cow manure should be used. If the soil is stiff clay a dressing of stable manure and lime would improve it, and be beneficial to the health of the plants. The ground should be ready for planting by the middle of October if possible.

In choosing a situation an open spot should be selected for the beds, so that the plants will have all the benefit of light and air (very important aids to successful cultivation), sheltered from the cold cutting winds, but not overshadowed by trees. In very exposed places shrubs should be planted to break the force of the wind, but they should not be planted too near them, otherwise they will impoverish the soil.

PLANTING.

The best time to plant Hybrid Perpetuals and others of a similar nature is in October and November. If the ground is in proper condition for planting the soil should work clean, so that the roots may not be puddled in the operation. All the large roots should be cut back to about 9 inches to produce fibrous ones. The holes should be about 6 inches to 9 inches deep for standards, but dwarfs require deeper planting; the union with the stock should be about 1 inch below the surface to cause the Rose to throw out its own roots. Make the holes wide enough to allow the roots to be spread out evenly, working in fine soil around them, and making the ground firm by treading it well. The distance apart for standards should be about 2 feet 6 inches to 3 feet, dwarfs should be from 18 inches to 2 feet, according to the sorts. After planting, place a firm stake to those that require it, to prevent the wind blowing them about.

PRUNING.

This must entirely depend on the class to which the plants belong, the growth they make, and whether you want Roses for exhibition or for general purposes; if for the former they should be cut hard back, but for general purposes to four or five eyes. Strong-growing sorts will not require to be cut so hard as weaker ones. If we could be sure that we were not to have any spring frosts, I should say prune your Roses in the autumn; but as we have no warranty concerning the weather, it is preferable to perform that operation in March, so that by the time they begin to make growth the season will have so far advanced that there will be no danger of injury from frost.

PROPAGATION.

The Rose is propagated in various ways—namely, by seeds, cuttings, layers, grafting, and budding. Propagation by seeds is performed with a view of obtaining new sorts. The fruit should remain on the plants until quite ripe. Sow the seed in pans in a compost of loam, leaf soil, and silver sand, covering them to the depth of about half an inch. The pans should then be placed in a cold frame, putting a sheet of glass over them, and covering the same with paper until the seed germinates. As soon as the plants are large enough they should be pricked out, and watering and shading attended to. In October they should be taken up, the tap roots shortened, and replanted in a sheltered spot, from 6 inches to 1 foot apart, according to size.

Cuttings strike freely in autumn and spring, and should be from 6 inches to 1 foot long, consisting of well-ripened wood. If struck out of doors they should be placed on a north border, working in some sand and leaf soil. They should be planted 6 inches deep, treading the soil firmly and afterwards watering it. Cuttings in pots should be placed in a cold frame for about a month, and then in a little bottom heat. When rooted pot singly into 54's, and place in a cold frame until strong enough for planting out in the beds, or potted on as required.

Rose-grafting should be done from January to March. The stocks should be established in small pots, and placed in heat a week before the operation is carried out. The scions should be from 2 inches to 3 inches in length, and consist of well-ripened shoots. Make a diagonal cut in the stock, and the scion must be cut to match, so that the inner bark of both are in contact. Bind the two firmly together with raffia, place in bottom heat, and keep close till the union is completed, when they should be gradually hardened off. All suckers that spring from the stock must be stopped as soon as they appear.

Layering is done by bending down a shoot of the Rose after making a cut right under and beyond a bud, the cut part being pegged down about 1 inch underground, inserting a piece of crock in the cut to keep it open; give water as required. In due time roots will be emitted from the severed bud, and the branch, when cut away with the newly formed roots, will be an independent plant. Midsummer is the best time for this business, when the Rose is in full growth.

Rose-budding is an art which is much easier to perform than describe, but is no doubt the best method of propagation in this case. The stock generally used is the Dog Rose for standards and half-standards. They are got from hedges in autumn. For dwarfs the seedling Briar is much used. The stocks should be planted in suitable soil, 1 foot apart in the rows and 3 feet asunder. As soon as the buds begin to push in spring they should be rubbed off with the exception of two or three nearest the top. If they are strong the budding should be done in July. When the wood is in proper condition select strong buds of half-ripened wood, of the sorts you wish to propagate; these should be kept moist in damp moss. Make a slit in the bark, then loosen the sides with the handle of the knife; cut your bud, and carefully remove the wood inside. See that you do not take out the heart of the bud with the wood, and do not bruise the inner bark. Insert the bud as quickly as possible, tying it in firmly. When the buds begin to move attention

must be given to loosening the ties as required. When the shoots have made growth they should be secured to something to support them, or the wind will blow them out, and your labour will be in vain.

(To be continued.)

THE NATIONAL AURICULA AND THE NATIONAL CARNATION AND PICOTEE SOCIETIES.

(SOUTHERN SECTION.)

THE annual meeting of the members of these Societies took place in the room of the Horticultural Club, "Hotel Windsor," Victoria Street, Westminster, on the 23rd inst., the Rev. H. H. D'Ombraïn (Chairman of the Committee) presiding; there being also present—Messrs. S. Hibberd (Treasurer), J. Douglas (Secretary), H. Turner, R. Dean, T. E. Henwood, J. Lakin, &c. The notice convening the meeting and the minutes of previous meeting having been read, the accounts were presented by the Treasurer, as follows:—National Auricula Society—Receipts, including subscriptions, £51 0s. 6d., and balance in hand, £33—£91 12s.; and expenditure, including £61 12s. 6d. prize money, £73 14s. 9d.; leaving a balance in favour of the Treasurer of £17 17s. 4d. National Carnation and Picotee Society—Receipts (including balance in hand, £11 6s., and subscriptions, £39 18s. 6d.)—£59 7s. Expenditure (including prize money, £39 18s. 6d.) £52 3s. 2d.; leaving a balance in hand of £7 3s. 10d. It should be stated, as attesting to the healthy financial position of both Societies, that no part of the £30 usually given by the Royal Horticultural Society was forthcoming during 1888.

The accounts were remitted to the auditors, and it was agreed that the financial year should for the future close on September 29th. The Chairman was requested to send a letter of condolence to Mrs. Whitbourn on the death of her husband, the late President of the National Auricula Society. Mr. Shirley Hibberd was elected President; Dr. Hogg, Dr. Masters, Mr. J. T. D. Llewelyn, and Mr. Harry Veitch Vice-Presidents. Mr. T. E. Henwood was elected Treasurer in the place of Mr. S. Hibberd, and the Committee for the ensuing year consists of Messrs. H. Cannell, E. Hill, J. James, R. Dean, C. Phillips, G. Wheelwright, W. L. Walker, H. Turner, and T. S. Ware, the Rev. H. H. D'Ombraïn being Chairman. In the case of the National Carnation and Picotee Society, the President and Vice-Presidents were elected. The names of Messrs. J. Fraser, J. Laing, and B. S. Williams were removed from the Committee, and those of Messrs. W. L. Walker, J. Lakin, and H. W. Headland added. Mr. T. E. Henwood was appointed Treasurer of this Society also, and Mr. J. Douglas Secretary of both. The question of appointing the judges was referred to the Committee. In reference to the place of exhibition in 1889, it was thought advisable that the Directors of the Crystal Palace should be approached to see if they would be willing to provide accommodation for the shows in 1889, and also make a donation to the funds, and the Rev. H. H. D'Ombraïn and Mr. S. Hibberd were appointed a deputation for that purpose.

CATERPILLARS AND BIRDS.

IN the article quoted on page 343 of the Journal on caterpillars in the past season, the writer says he considers it a mistake to attribute the increase of these pests to the destruction of sparrows by farmers' clubs, &c., and in this most persons who have studied the subject will probably agree. Several articles and paragraphs in favour of sparrows have appeared in country newspapers, some of a merely sentimental type, others showing considerable ignorance, such as calling sparrows insectivorous birds, and others, of a more plausible character, adducing the evidence of ornithologists, and asserting that the balance of Nature is impaired with the usual evil results by the destruction of sparrows. It is true that some ornithologists, and among them, I believe, Yarrell, who is considered a standard authority, have declared that sparrows do more good by destroying insects during the breeding season than harm at other times, but it seems doubtful if their statistics and experiments were exhaustive. The opinion of Miss Ormerod, the acknowledged authority upon insects destructive to agriculture and vegetation, will probably carry more weight in these days, and she has declared, I believe, emphatically against the sparrow. It is true, too, that if man seriously impairs the balance of Nature he will probably suffer for it; but the fact is that the balance has been destroyed in favour of sparrows, who have been artificially (though unintentionally) fed and protected by man. For by building houses and barns we furnish them with safe nesting places, and by feeding animals, poultry, &c., in open troughs and on the ground, we provide them with special food in the winter, and thus ourselves contribute to their undue increase. The theory that we should not interfere with the balance of Nature, though true in the main, may be carried too far. I was once told it was a mistake to destroy the grubs upon my Roses, as they would thin the buds for me. True, perhaps, but still I thought I would like to do the thinning myself. A well-known nurseryman once employed some women to disbud his Roses for him in view of the shows. They worked zealously, and their employer found, when he came to inspect the plants

operated on, that they had cleared off every bud. I fear that caterpillars would be found to be even less teachable.

One of the most serious injuries inflicted by sparrows is done indirectly. It is pretty well known that the majority of insects are winged in the perfect state and celebrate their nuptials in the air, and the birds especially designed by Providence to keep down insects by destroying them in the perfect state in the air before the female has laid her eggs are swallows and martins. The latter, however, finds an implacable foe in the sparrow, who ousts her from her mud-built nest and takes possession of it himself. The rows of martins' nests under the cottage eaves which used to be so common are now almost unknown in some districts, and there seems little doubt that in those places the sparrows will soon extirpate the martins if they have not done so already.

Being fond of birds, I have always been ready to believe all good qualities attributed to them, and accordingly when some years ago a pair of blue tomits hatched a numerous brood of young in the crevice of a wall which partly enclosed a quarter of an acre of Roses, I thought I should have some real assistance in keeping down caterpillars among the Roses during the month of May; but though I spent several half-hours in watching the old birds feeding their young they never once, as far as I could see, went into the Rose trees, where caterpillars and grubs abounded, in search of food, but always up into the large Beech and forest trees, and I was obliged to conclude that, as far as Roses were concerned, tomits were a fraud.

It is asserted that sparrows feed their young on caterpillars (they may do so in the early summer when they get nothing better), but it is my belief that they would prefer first anything in the way of fruit or grain, even corn in "the milk," and next perfect insects of any sort. I should say that no bird, except perhaps a cuckoo, would regularly eat caterpillars, which in that stage appear to have ichneumon flies and other predatory insects as their natural foes. Fowls will not touch them, even the omnivorous duck will not have them.

To keep injurious insects in due restraint it is evidently more important that they should be destroyed in the perfect state than as grubs or caterpillars, and therefore, remembering their enmity to the martins as well as their own many grievous misdeeds, farmers and gardeners will probably do well to wage war against sparrows, till at all events their numbers be reduced to a more reasonable level.—W. R. RAILLEM.

FRUIT FORCING.

FIGS.—Early-forced Trees in Pots.—Trees intended for this purpose should, if they have been placed in the open air, be taken under cover to protect them from the cold autumn rains. It is presumed that they have been repotted, or had the drainage rectified, as advised in a former calendar. Place the trees in a rather dry, well-ventilated house. Any thinning or shortening crowded attenuated growths must be attended to, and the trees dressed with an insecticide after washing thoroughly in every part with a solution of soft soap, 8 ozs. to the gallon of tepid water, applying with a brush, which must be sufficiently stiff to dislodge scale if there be any, and it must be used judiciously as well as efficiently. A dish of forced Figs is now considered a necessity in large establishments, and is not by any means difficult to obtain. A light well-ventilated house is necessary, having pits containing fermenting materials to afford bottom heat to stimulate the roots and afford a constant supply of nutritive matter. The Fig requires abundance of liquid manure when growing, the trees being most prolific under limited root space. One of the great advantages of Fig culture in pots is the number of varieties that may be grown in a house of moderate dimensions, and which, if forced, come in at a time when the dessert is not too varied. Brown Turkey is unquestionably the best of all Figs for every purpose, a fitting companion being White Marseilles, they, with the following, being well suited for forcing and pot culture:—Early Violet, Black Ischia, Brown Ischia, Black Marseilles, Violette de Bordeaux, Negro Largo, Angelique, White Ischia, Col di Signora Bianca, and Royal Vineyard.

Planted-out Figs.—Figs that have been in bearing since middle June are now commencing to rest, and may be divested of the old foliage as soon as it parts freely from the wood. If planted in inside borders and the growth is considered too strong, the present is a favourable time for root-pruning, an operation that can scarcely be overdone, particularly where the space is limited. All inert soil should be cleared away, strong roots cut out, and the drainage examined. The young roots may then be relaid in fresh compost, firmly rammed mulched, and left dry until the time arrives for forcing. The young

shoots that have been allowed to grow up to the glass will be thickly studded with embryo fruits, which must be protected from injury when the trees, &c., are cleaned, as well as from the effects of sudden and severe frosts, by being unfastened and drawn down below the trellis until the time arrives for thinning out the branches that have reached the extremity of the trellis. The best soil for Figs is a good friable loam with a liberal addition of lime rubble, broken bricks, and steamed bonemeal. Stimulants, in the form of solid manure or liquid, should always be applied to the surface when the trees are growing.

Late Trees.—Have all root-pruning finished, bearing in mind that strong-growing varieties, when confined to limited root space, can only be kept fruitful and manageable by limiting the rooting area and feeding when carrying heavy crops of fruit. The houses should then be freely ventilated, especially at night, except when frosts prevail.

STRAWBERRIES IN POTS.—Much of the success in Strawberry forcing depends on the treatment the plants are subjected to at what is commonly known as the resting period prior to forcing. The wintering of Strawberries in pots by stacking them one upon another in sawdust or other material against a wall, or housing them on the borders of fruit houses, is not only unnecessary but absolutely injurious, as the soil not infrequently becomes dry, and the dry atmosphere induced by the free ventilation wastes the energies of the plants. Plants that have had the crowns thinned in the season, the side shoots removed and kept to one crown, will have them well developed, having made their growth early, and have the pots filled with healthy roots. If intended for early forcing they will be the better for having lights placed over them, the pots being plunged in ashes or cocoa-nut fibre refuse, or even tree leaves, but not so thick as to heat, but the lights must be withdrawn in mild weather, and only used in case of heavy rains, when they must be tilted, or in case of frost. They should be regularly supplied with water at the roots, as the Strawberry never suffers so much as when allowed to become dry at the roots. Place late plants in a raised bed or plunged in ashes or other material on the flat in a sunny position to finish the ripening process, and they will require to be well supplied with water. Sun and sharp winds ripen the growths and solidify the crowns far better than the atmosphere of houses.

Autumn fruiting plants require a steady night temperature of 55° to 60°, and 10° to 15° rise by day; ventilate freely so as to prevent the condensation of moisture on the fruit, as that will cause its speedy decay.

PLANT HOUSES.

The Stove.—The temperature of this structure should now range at night from 60° to 65° according to external conditions, while the day temperature by sun heat may range 10° to 15° higher. The day temperature by fire heat, when necessary to apply it, should not exceed 70°. Considerably less moisture will be needed from the present time, and judgment must be used in syringing. On fine days syringing may still be done twice, while on all damp dull occasions it must be dispensed with, only damping between the pots. When syringing, however, do it liberally, in order to keep Crotons and similar plants free from red spider and thrips. Shading will no longer be needed, for all plants in this structure will now bear full sunshine without injury. If Phalænopses or Orchids of a similar nature that cannot bear strong sunshine are suspended in this structure they will still need a little shade, but these can be protected by sheets of light paper without interfering with the other occupants of the house.

Crotons.—All well-grown highly coloured young plants in 5 to 10-inch pots that have been specially grown for room and table decoration should still be kept in a lower temperature than the stove. To excite fresh growth now would spoil them for the purpose for which they have been prepared. It is impossible to colour any foliage that may be made after the present time. Keep them in a night temperature of 55°, and ventilate on sunny days to prevent the temperature rising above 75°. Do not subject the plants to cold draughts, rather allow the temperature to run up 10° higher.

Dracenas.—Plants of the *D. Cooperi* and *D. terminalis* types are much better under similar conditions to those advised for Crotons than in a close moist atmosphere, that is, when they are required for the various forms of room ornamentation. They last in good condition nearly double the length of time. Plants of *Goldiana* should not be starved, for they are liable to lose the brightness they would otherwise possess, while *D. Lindenii* will bear the treatment advised for *D. Cooperi* without injury.

THE BEE-KEEPER.

BEEES AND THEIR ENEMIES.

BEEES have numerous enemies, but few have the power to annihilate them. The elements and man are perhaps the two greatest they have to contend with. The former can, to a great extent, be combated, and evils arising therefrom be avoided with a little care; but, alas! the manipulation they are subjected to! Often a floor has been provided. There will be little damp inside the hive, but where not there will be dirt, and the health of the bees jeopardised. We have never observed anyone but ourselves warning against this evil. The time to remedy it is not, as yet, too late.

All those who have been trying the injudicious rapid feeding lately should make an examination of the interior of their hives, and if damp, change the frames and bees to a warm and dry hive. Where that cannot be done change the floor-board. Damp during winter is the bane of bee-keeping, but dryness is the sure way to success.

There can be no better lesson than either to see an apiary properly prepared for the winter, or to have an accurate description of one. As usual I have parted with my surplus bees to persons in want of such. My stocks for the winter comprise small nuclei and strong stocks in equal numbers. With one exception all are prepared as stated in the number of October the 18th, and supplied with plenty of honey that will last them till next summer, and as they have gathered much pollen this fine October, are in a fit state to stand the winter and come out strong in spring, although my nuclei, as usual, are weak in bees.

One of my hives had an imported Carniolian introduced a month ago. It had then been queenless for some time, and had dwindled down to less than a teacupful of bees, but the persecuted drones from the other hives previously mentioned as being queenless or having unfertilised queens, took shelter in this hive, enabling it to put in a good patch of brood that when hatched will greatly benefit it, and I expect it will survive the winter. It is rather singular to see one hive in direct need of drones, yet the bees turning them out, while another having a fertile queen retaining them. The only use they are now is to assist in hatching the brood, which without them could not be accomplished. To-day while I write is the twenty-seventh day since the introduction of the queen and the first attempt to kill the drones. As the brood hatches they will be turned out. I may, before closing this article, state that while it is unadvisable with any variety of bee to change their site or appearance, Carniolians are very sensitive to any change being made either of site or of hive. It is therefore important not to make the slightest alteration or change now with Carniolian bee hives; no variety clings to a position taken up like them.—A LANARKSHIRE BEE-KEEPER.

BIRDS AND BEES.

I AM surprised that any bee-keepers should have doubted that martins as well as swallows and sparrows are most destructive to bees. From my own observation I should say there is not a pin to choose between them, though sparrows are far the boldest. The other day I saw an old cock sparrow catch five bees on the wing in two minutes; he sat on the top of the hive and pounced at them as they came home, but I have never seen them eat drones. When the ground was covered with the dead and dying the sparrows carefully picked out live workers, while the swallows and martins (chiefly the former) scud after the bees as they come home before a shower, and catch hundreds on the wing, and when a swarm has turned out they will fly backwards and forwards through the cloud of bees. I have seen this times out of number.—W. E. BURKITT, *Buttermere Rectory*.

TRADE CATALOGUES RECEIVED.

James Cocker & Sons, Aberdeen.—*Catalogues of Roses, Trees, Herbaceous Plants, &c.*

TO CORRESPONDENTS

•• All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Addresses (*S. Bacchus*).—Write to Mr. E. Molyneux, Swanmore Gardens, Bishop's Waltham, Hants. (J. C).—Mr. W. Collins, Martinhoe Terrace, Martindale Road, Clapham Park, London, S.W.

New Grape.—Will the correspondent who sent us a new white Grape oblige by writing us again, giving his name and postal address?

Chrysanthemums (Berwickshire).—You had better arrange the plants in a light house at once, and carry out the proposals in your letter, which only arrived just in time for this brief reply.

Royal Horticultural Society (W. T.).—We have had pleasure in sending your letter to the Secretary of the Royal Horticultural Society, who will no doubt advise you on the matter.

New Varieties of Potatoes (Tester).—We have received your letter, and shall be glad to hear if you have any particular objection to our appending your name to it if printed. There has evidently been a mistake somewhere. The question is where? Is it not better to find out where the fault lies before pronouncing condemnation?

White Glove (D. W.).—It is the habit of this variety to split at the calyx; but it has done so to a very large extent this season, due undoubtedly to the wet season. From the description you give we should say you have the true variety. We do not know of one better suited for outdoor culture if you have the variety known as The Bride. It is free, a strong grower, and yields flowers abundantly.

Propagating Early-flowering Chrysanthemums (F. Partridge).—It is singular the last winter should have killed all your old plants in Cornwall. Every one of ours passed through it safely in a garden near London. As you say there are plenty of cuttings at the base of your plants now, by all means strike some of them in a close cool frame, leaving them there through the winter. If you do not take the cuttings now they will perhaps be killed. You can strike more in spring if you wish by taking the tops off the young plants and rooting them in gentle heat.

Grapes Scalding (W. Simpson).—You ask if we will insert your communication. We shall have great pleasure in doing so, also one we have in hand from Mr. W. Bardney, as soon as possible. The great pressure on our columns just now is only temporary. The subject of Grapes scalding is neither exhausted nor settled. We know of houses of Lady Downe's Grapes in which scalding is practically unknown; also a house of Black Hamburgs in which it was not possible to prevent the fruit of one Vine scalding by any method of ventilation, while not one injured berry was seen on the other Vines in the same house. Can those of our correspondents who feel their mastery of the subject solve the problem in that case?

Petroleum and Tomato Houses (F. W.).—We do not think the ordinary petroleum would do; it is very volatile, and would answer the purpose only as long as the oil would last. We should not advise you to paint the woodwork of the houses with lime and petroleum. The latter would not add much to the adhering properties of the former. Paint the houses with pure petroleum for the fly, and then paint the woodwork with good white lead and boiled linseed oil, with a very little turpentine intermixed with much of the latter, or it will destroy the lead and be no better on your houses than ordinary whitewash. If painted every year with petroleum it would certainly prevent a large amount of moisture penetrating the wood, but we should prefer the paint.

Marechal Niel Rose (C. H. S.).—Your plant was cankered, the fate of thousands, and a disease this variety is very subject to. When growth has ceased remove the side shoots and the unripe end of the main shoot, and it possibly will flower in the spring if the wood is sufficiently ripened. If well ripened it may show flowers from most of the buds along the shoot; if so, remove a portion of the flowers, and only allow the plant to develop a certain number, say a dozen to a dozen and a half. After the plant has flowered prune it well and encourage it to make strong growths again from the base of this season's growth. Train them sufficiently far apart, so that they will have a good chance to ripen. Top-dress or mulch with manure the border containing the roots if you think it needs assistance.

Rhododendrons in Shade (W. H. M.).—We have seen Rhododendrons flower very well, but not with equal freedom every year, in shaded places in the south, but we are not able to give an assurance that they would do so in a sunless border in your northerly district. There would be no difficulty in procuring some that would flower freely the first year, but whether they would ripen their growth and set buds for flowering the following season is doubtful. Your not distant neighbour, Mr. William Thomson of Clovenfords, is competent to advise on the matter, and we feel sure he would do so if requested. If you decide to make the experiment, and will either state the number of shrubs you would like to plant or give the dimensions of the border, we will name some free-flowering varieties of compact habit, as we suspect you have not room for strong growers.

Tomato Plants Diseased (H. R. S.).—The leaves sent are infested with the fungus so fatal to these plants, and is similar to the dreaded Potato disease, for which a cure is practically hopeless, therefore efforts should be directed against the spread of the disease. All tissue or parts of the plants attacked should be burned. Damp and confined air favour the fungi, hence gentle heat to cause a circulation of air and rather free ventilation should be afforded. A firm soil, and not too rich, so as to insure a sturdy growth, thoroughly solidified by full exposure of the foliage to light and air, and old mortar rubbish or road scrapings may be mixed with the soil in view of strengthening the plants, and so render them better able to resist the disease. Care should be taken to remove every particle of soil in which the plants are grown, not using it

again; indeed it should be burned, and seed saved only from perfectly healthy plants.

Pipes for a Cucumber House (G. R.).—We advise you to use the same sized pipes for the mains as are used for the flow pipe in the house with which you wish to connect your pipes for your new structure. The quantity of piping required depends upon the height of the house, which you fail to give, as well as the length and width; also whether you want Cucumbers early in the season or through the winter. For winter or early work it would be necessary to have four 4-inch pipes the whole length of the house—that is, two down the centre, one on each side of the path; the other two, one on each side of the house near the outer walls, or between the outer walls and the wall intended for supporting the bed in which you will plant the Cucumbers. To do this two extra walls for forming the beds independent of the outer walls would be necessary. The soil in the beds could be kept many degrees warmer than if it came in contact with the outer walls. The extra walls are not necessary for planting early in April. You would also need two 4-inch pipes for bottom heat, one for each bed, which you should be careful not to bury too deeply.

Celery Decaying (James Percival).—It is indeed unfortunate that "thousands of plants" should decay at the neck as in the examples you have sent. You say the "plants were good when placed in the trenches early in June, and they never grew afterwards, the roots appearing to have rotted off." The plants we received were certainly too large for transplanting successfully, and must have been forced on in some way to have attained their size early in June. In that case the check and change would arrest growth at the outset, from which they could scarcely be expected to recover except under the most favourable weather conditions. Constant sprinklings, either artificially or from light and frequent showers, keeping the ground very wet on the surface while it is drier below, are apt to cause decay; but in your case we incline to attribute the cause to the serious check such large plants must have received in removal, and the possible cold and inclement weather following. Some small millipedes were present, but these may have been the result of the decay, not the cause, though when numerous in the soil they often do much injury to plants and crops.

Caterpillars Destroying Cabbages (Surrey).—The specimen sent is a caterpillar of *Trypæna pronuba*, the great yellow underwing moth, about half-grown. Caterpillars of this species feed upon the roots and underground stems of many plants in the kitchen garden, being discoverable from August until May. They become more or less torpid during winter. It has been recommended to hunt down the moth in its season—viz., July and August, as it moves sluggishly by day, and is conspicuous owing to its yellow "under wings." Frequently it flies to the lights in houses or public buildings. Amongst the Cabbage rows, where the insect is known or suspected to be doing mischief, the application of soot to the roots well dug in has been of proved utility. Some advise the careful application of gaslime which has been kept for a time; but probably the best application at the present time would be a solution of petroleum, half a fluid ounce of the oil being dissolved in a gallon of weak soapsuds, a little of this being poured round the plants; it will not injure them provided they are established. Plants that are being planted should have their roots immersed in a puddle of soot and soil in equal quantities before insertion.

Ham Green Favourite Tomato (G. A. Crocker).—We comply with your request in not publishing your letter, but when you say you "wish nothing further printed on the matter" of the above Tomato we must remind you it is grown in a public garden for a public purpose. We have never pretended to say the variety named is the best of all in the house at Chiswick. It is a strong grower and has borne good fruit. The words "apparently a selection from Hathaway's Excelsior" we will alter to "apparently an improvement" on that variety if you like, and both convey a favourable estimate. But all the same, Perfection has afforded the finest fruits that have realised the highest price, while Horsford's Prelude has produced the greatest number of rather too small fruits for market but of excellent quality, and proved decidedly the freest setter of any in the house. An official report will probably be published at the close of the season. We are obliged by the information that "Ham Green Favourite is a *bona fide* cross, though you did not carefully take note of the parents, but know one of them is not Hathaway's Excelsior, as you did not grow it at the time." Perhaps your seedling is a vigorous grandchild of Hathaway's. There is certainly a resemblance between them, but this in no way detracts from the merit of the former.

Grafting Tea Roses (Ruga).—Grafting can be done at almost any time provided the stocks and scions are in suitable condition, but is generally delayed until after the turn of the year, as with increased light and heat from natural causes the plants then grow with vigour after the union is complete. Grafting usually commences in January, using wood in a dormant state or nearly so, and the stocks must be in the same condition. It is not necessary that the plants from which scions are taken should have flowered if you are certain that the varieties are true. The greatest success by a beginner would be attained by starting his plants from which the scions are to be taken in heat and the stocks also until the sap has commenced rising freely. The wood of the scion should be nearly half ripe; it should have at any rate a certain amount of solidity. It is not necessary to introduce the stocks into heat as early, the scions producing plants. Still, if you work any in a dormant state you may introduce the two together, and when the sap in both commences flowing grafting can be performed. One eye on

each scion is ample. It will be necessary to have a close frame, the same as you would employ for propagating, to place them in after they are grafted, and if slight bottom heat can be given them all the better. This is especially necessary when moderately young wood is used for scions.

Asparagus plumosus nanus (*J. E.*).—This plant is raised from seed, but we cannot say where seed is obtainable. It is a dwarf plant only in a young state, and these are confined to those that persist in dividing their crowns instead of gaining much strength. Plants of this nature, therefore, are dwarf, but you might grow a hundred plants before one would assume this character. You could easily raise *Adiantum euneatum* from spores. It is a light graceful plant, and would look well with *Gloxinias*. You could not do better than grow *Begonia* Ingrami, *B. Knowsleyana*, *B. nitida alba*, and *B. n. rosea*, *B. semperflorens gigantea carminea*, *B. parviflora*, and *B. fuchsoides*, which flower well during the winter. You may not be able to obtain seed of all, but for the price of a packet of seed you would be able to buy a plant, and this class of *Begonias* can be propagated rapidly. If you secure the dwarf strain of *Cinerarias* you could not have anything much better. You could have plants in 4 to 6-inch pots that would not exceed 6 inches to 1 foot in height with large heads of bloom. Grow *Primula obconica*. You could grow *Celosias*, red and yellow, if not too tall. You could grow the red and white forms of *Globe Amaranthus* and *Cyclamen*. For that reason the selection is a limited one if the compact habit of *Cinerarias* does not suit you. There are many plants for flowering at that period that would suit you, but they cannot be obtained from seed.

Odontoglossum vexillarium (*J. P.*).—The foliage of the old pseudo-bulbs will naturally turn yellow, but if the yellow leaf sent is from young growths something is certainly wrong. We think, however, that you need not be alarmed, as the plants have commenced fresh growth, though instead of starting now, the growth should have been well advanced. The temperature of the house should range from the present time throughout the winter from 55° to 60° at night according to external conditions. During mild weather, when the outside thermometer registers from 40° to 45°, the inside temperature may with safety exceed 60°. Under such circumstances the pipes should be kept just warm, even if the temperature rises considerably above the figures given. When the mercury outside falls, say to 35°, then 55° at night should not be exceeded in the house. If the weather prove exceptionally severe, the temperature by morning may be allowed to fall with safety 2° or 3° lower. You have excluded too much light from your plants, and at the same time had the atmosphere too moist and cool. That is the cause of the "spot" on the leaves. Maintain the temperature advised, and be careful not to overwater the plants or have the atmosphere too moist. When water is applied either to the foliage or roots, be careful that it is a few degrees warmer than the temperature of the house. You may have over-ventilated; less air will now be necessary, and cold draughts must be avoided; then, if the plants are kept clean, they will soon grow out of their spotted appearance.

Orchard House Fruit Culture (*B.*).—You had better write to Mr. Rivers, Sawbridgeworth, on the question of books, and we have no doubt you will be able to obtain from him what you desire. Grapes certainly do not pay at the price you name, unless the houses in which they are grown are turned to other account and a fair remuneration obtained from them independent of the yield from the Vines. Hitherto we have been of opinion that Vines paid better to grow at present prices than Peaches and Nectarines, that is, unless the latter are forced early, when they realise a good price and may then pay slightly better than Grapes, although this is very questionable, for good Grapes early in the season realise fair prices. We can readily understand Peaches and Nectarines being scarce and dear a short time ago, for then all the indoor fruit would be over except the latest kinds grown in practically unheated houses. The vineries of which you speak could readily be turned into Peach houses without much labour. The addition to the border and the trees would be the most serious item, and even this depends on the nature of the soil in which the Vines are growing. It is just possible all that would be needed would be a thorough trenching of the border and the addition of manure. If one house was set apart for the trees, the permanent ones could be placed in their right positions with others between them for placing in houses when they attained sufficient size. But this is really a matter for the consideration of those who may have the carrying out of this work.

Improving Cricket Ground (*W.*).—The ground being much "knocked about," it will be necessary to lay fresh turf in the worst parts, patching it with similar turf to that of the ground and so as to keep the same evenness of surface, as "bumpy" ground is highly objectionable. Before interfering with the ground have it well raked over with an iron rake, so as to open the surface, then patch it as advised, and dress at once with short stable manure not too much decomposed, applying at the rate of twenty cartloads per acre. Distribute it evenly and leave it until the first favourable weather after the middle of February, then rake over with a wood rake to still further distribute the manure evenly and removing any littery portions. When the grass begins growing rub well in with the back of a wood rake or bush harrow, remove any rough parts with stones, &c., rolling well down. The rolling should be frequently repeated, and if the grass is kept duly mown and rolled you ought to have a wicket in capital order at the opening of the season. If you cannot procure short stable manure use the shortest farmyard obtainable and comparatively fresh. Avoid old

soapy stuff which possesses little manurial value. If the grass be thin sow over it after the ground is cleared and before rolling 8 lbs. *Cynosurus cristatus* and 4 lbs. *Festuca tenuifolia* for 1 acre, and if very thin 4 lbs. *Festuca tenuifolia*. If the grass grows sufficiently vigorous it may only be necessary to apply a dressing of compost, such as decayed vegetable refuse from the rubbish heap, any woody portions being burned or charred. It should be given now.

Names of Fruits.—The names and addresses of senders of fruit to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. (*W. C. Harant*).—1, Pitmaston Russet; 2, Pearson's Plate; 3, Nanny; 4, Catillae; 5, Doyenné du Comice. (*J. C. M.*).—1, Hanwell Souring; 2, Red Calville; 3, Winter Greening; 4, not known. (*Lee, Kent*).—Pears too much decayed. (*T. C. Price*).—1, Cellini. The others not known, probably orchard seedlings. (*A. L.*).—1, Marie Louise d'Uccle; 2, White Doyenné; 3, Van Mons Leon Leclerc; 4, Beurré d'Amanlis; 5, Beurré Langelier; 6, Brougham. (*D. H.*).—1, King of the Pippins; 2, Yorkshire Greening; 3, Golden Noble; 4, Kerry Pippin; 5, Pearson's Plate; 6, Northern Greening. (*J. H. H.*).—1, Golden Reinette; 2, Herefordshire Pearmain; 3, Cox's Orange Pippin; 4, Dutch Mignonne; 5, Pine Apple Russet; 6, Dumelow's Seedling. (*T. Cooper*).—1, Bedfordshire Foundling; 2, Alfriston; 3, Minchall Crab; 4, Trumpington; 5, Knight's Monarch. (*J. M.*).—1, Five-crowned Pippin; 2, Alfriston; 3, Striped Beefing; 4, Cox's Orange Pippin; 5, Dutch Mignonne; 6, Catillae. (*H. M.*).—Greenup's Pippin. We have two collections of six Apples each, also two letters, one from "Joseph Harrison" and one from "Lee Kent," but do not know to which collections these names apply. If other fruits are sent they shall have attention.

Names of Plants.—We only undertake to name species of plants, not varieties that have originated from seed and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in firm boxes. Slightly damp moss or soft green leaves form the best packing, dry cotton wool the worst. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*J. R. Drake*).—We shall have great pleasure in naming the plant or shrub if a specimen is sent enabling us to do so, or some particulars given that may assist in its identity. In the absence of these the shrivelled sprays are insufficient for the purpose. (*W. H.*).—*Cestrum aurantiaum*. (*R. T. Portugal*).—The plant is common Millet (*Panicum milliaceum*), and no doubt it is the same as you say is used for brooms, as it is grown in America rather extensively.

COVENT GARDEN MARKET.—OCTOBER 24TH.

Our Market is now very quiet, prices remaining much the same all round. Several consignments of Canadian and Nova Scotian Apples have reached us during the past week. Samples indifferent.

SHELTER AND FOOD FOR LIVE STOCK.

SHELTER, litter, and food are the chief factors to success in the case of live stock in winter. Frequently do we meet with statements of how much exposure animals will bear, but they cannot undergo such exposure without a loss of condition, to say nothing of the suffering involved by it, and it is clearly in the interest of every farmer that we advise close attention to the comfort and health of every animal upon the farm now and onwards during the cold season of the year. A day or two ago, in one of our drives, we saw a herd of cows turned out to graze upon a common. Several of the cows had the whole of one side discoloured by the foulness upon which they had been lying the previous night. We knew by this that the cows had not been well cared for; we were not surprised, for we have repeatedly seen them so ill treated when they are taken into the yards for shelter.

Let us consider what shelter really means. It is a comprehensive term embracing the protection of animals from exposure to anything likely to prove hurtful to them. We build lodges, sheds, and covered yards, and we do well, but we must also insist upon dry bedding and thorough drainage. Never shall we forget the lamentable sight of a herd of choice cattle standing knee deep in litter almost afloat with water at midwinter. This happened, not in the yard of a poor man, but at a home farm replete with every modern appliance and improvement that steward or builder could suggest to a generous enthusiastic landlord. The drains had been suffered to become choked or clogged by the litter, and the poor animals suffered accordingly. Not only must yard and building be well drained, but equal care and attention must be given to the daily clearance of all foul litter, for if cattle are made to lie upon beds covered by dry litter overlying other that is sodden with moisture, they are exposed to a risk of rheumatism which involves suffering, a falling off in condition, and it may be a positive loss. This is just one of those simple matters of detail so often overlooked, yet in which negligence is the cause of much mischief.

Not only to shelter must we look for the warmth necessary to health in winter, but to a wholesome and abundant dietary. The present autumn is remarkable for an abundance of food in the guise of corn, roots, and fodder. The temptation to have full yards of cattle once more is therefore greater—all the greater from the fact of improved prices. But it is now, rather than in spring, that a careful calculation of ways and means should be made. The calculation is simplicity itself. If made by gross weight or measure, a cow or full grown bullock requires about 90 lbs. of dry food daily, or half as much more of green food; a yearling requires about half, and a calf about one-fourth of this quantity. A horse requires from four to eight gallons of corn, according to its work, four gallons of pulped or minced roots, and as much fodder as it can consume weekly. All corn used for horses or cattle should be crushed; if given whole a weak animal cannot eat it, and we have often known Oats to pass through the

stomachs of young horses undigested. As we write we are having a large quantity of Barley and Sainfoin straw cut into chaff and mixed for general use during winter among horses and cattle. Horses especially require extra attention in winter. As a rule they should always be fed for two hours before leaving the stable in the morning. We never allow nose-bags to be used, as they are a temptation to a horseman to trust to feeding horses in part with them after the horses leave the stable. For young horse stock we prefer very large loose boxes rather than open yards with sheds in winter. If light can have free admittance there is no better place for them than one end of an old barn to winter in.

Before all things do not overstock the farm for the winter and spring; but too often by midwinter such inroads are made upon the store of food that a reduction is made in the daily quantity, the inevitable result of a falling off in condition in the animals. Any attempt to sell such stock in March involves a certain loss and consequent vexation. In making a calculation of possible requirements, the only safe plan is to provide for a late spring, and this can very well be done without running to the opposite extreme of keeping a superabundance of fodder or roots. If there is a flock (as there ought to be on every farm) we must take into account its special requirements also.

WORK ON THE HOME FARM.

The long spell of fine weather proves most welcome, and is an invaluable boon to every farmer. It enabled us to save the late corn in good condition, and the abundant second growth of Clover and Sainfoin has also been turned to good account. The Sainfoin had plenty of seed upon it; it was mown, and when the stems and leaves were sufficiently faded and dry for our purpose it was carted from the field straight to the threshing machine, the seed threshed out, and then the plant itself was cut up into chaff with an equal quantity of Barley straw. Two days of this chaff-cutting sufficed to fill one end of a barn, a little salt was scattered among it as it was taken in, a slight heating will follow, and we have thus secured a large supply of excellent chaff suitable for horses, cattle, or sheep. On another farm we had two fields of seed Tares, which harvested very slowly after the mowing, and we had the whole of them carted, threshed, and chaffed in the same manner as the Sainfoin. Some late Clover has also been cut into chaff, as we wanted the land cleared to plough it for Wheat. Part of that field of Clover was folded by sheep, but the crop was too heavy for the sheep to clear the whole of it, part had to be mown and the land dressed with farm-yard manure. Of course such late crops of forage might be turned to excellent account for silage, but it answered our purpose best to convert it into chaff.

Another important advantage arising from the fine autumn is such a chance as does not often come to us of getting rid of perennial weeds from foul land. Since harvest, late as it was, we have been able to plough foul light land, scarify, harrow, and clear the weeds upon the surface, plough, and repeat the entire process again where it was necessary. Glad indeed have we been to find that many other farmers have turned the fine weather to account in the same way, evidence of which has met us in the couch grass fires which we meet with in every district day after day. We take this as a sign that one of the most important lessons taught farmers by adversity is not to allow weeds to exist and rob the land of the fertility which costs them so much. Depend upon it, if farmers would limit the area of their occupations well within the scope of their means they would soon prosper and thrive again.

REMARKS.

14th.—A brilliant autumn day.
15th.—Overcast and cold morning; fine afternoon, clear night.
16th.—Foggy till about 11 A.M., then fine and bright. Solar halo in morning.
17th.—Dense fog till 10 A.M., afterwards fine, but rather hazy; foggy at night.
18th.—Foggy till about 11 A.M., then fine, though not clear.
19th.—Slight fog early, bright day and night.
20th.—Bright throughout. Lunar halo and pink auroral streamers at 11.40 P.M.
A rainless, cold and dry week, with high barometer, and light easterly wind.—
G. J. SYMONS.

THE AUTUMN.

IF, as is often said, and not without some truth, the autumn is the commencement of the gardening year (the season of planting), it will perhaps be conceded that the beginning has not on the whole been a very bad one. The change from more or less continuous showers that prevailed during what ought to have been summer to settled fine weather at the close has been most welcome, and the generally dry October, with acceptable rain at the end (for the ground is very dry) will leave its mark for good on fields and gardens. The fluctuations of temperature during the month have been extreme—one period representing 14° or 15° below the average, and the term succeeding an equal range above it. The sharp frost of the first few days will long be remembered, for the summer vegetable supply was till then maintained, Peas and Beans being as fresh and plentiful as is often the case in July; but these and other crops of a tender nature were destroyed in a night, with practically all flowers that were rendering gardens as gay as they had been at any period of the year. Unquestionably great injury was done, and in not a few cases individual losses were serious. Some growers of Chrysanthemums were taken by surprise, and many plants rendered worthless except for producing cuttings. The late varieties appear to have suffered the most, as might be expected from their being in active growth; the earlier, which had set their buds, were firmer and essentially more frost-resisting. One grower of late blooms for sale estimates his loss at £100 at least, and there must have been others who had not their plants housed that have suffered in proportion in localities where the frost was severe. The bitterly cold days preceding the destructive frost, however, were not lost on men who were on the alert and had structures ready for the reception of their plants, and many of these that could not be placed under glass were saved by laying them down and covering with mats at night, placing them in position in the daytime. It does not follow that the plants which apparently recovered from the nipping have not been checked to an extent that will injuriously affect the blooms, and those cultivators who had their plants safely arranged under glass during the last days of September will have the advantage over others who could not, or did not, make them secure at the same time. There can scarcely fail to be many unsymmetrical blooms this year through the effects of frost on the buds, many of which we have seen are not opening kindly, though there are plenty that are for ensuring effective displays during the Chrysanthemum month—November.

But though the frost referred to cut down vegetable crops, killed flowers, and injured certain plants, it is a question if the fine weather succeeding did not afford ample compensation in the beneficial effects it must have had in other important respects. Work in gardens and fields was seriously in arrear at the close of September. Ground was infested with weeds in spite of all efforts to subdue them. The harvest was far from completed, and there were infinitely more Potatoes in the ground than out of it, and the disease spreading. The dry weather gave an enormous impetus to work, and land was cleaned and valuable crops secured. Taking a broad view of the case, most persons will admit that the benefits resulting from the fine term that succeeded the frost greatly overbalanced the harm that was done by it. The dry October has, moreover, been of marked advantage to fruit trees. A month ago

they were growing rampantly, and there seemed few signs of the wood ripening, while a late planting season was generally expected, and that is of advantage to no one. The frost gave a decided check to growth, and the wood, owing to the dry weather, is in better condition now than at one time could have been anticipated. The favourable circumstances for land-cleaning and preparation have given a great stimulus to planting. Orders for fruit trees and Roses have flowed in freely, and execution has been brisk and planting active. Early defoliation through the effect of the frost has enabled a good early start being made in this work, and it is not improbable that much more of it will be done during the season than has been accomplished in any previous year. That trees will grow when well planted under favourable conditions in spring does not admit of doubt, but it is not the less wise to seize promptly and turn to the best account autumn advantages.

A wave of activity appears to be passing over the horticultural world. Fruit growers are very much on the alert—those that are established extending their plantations, while “beginners” are more numerous than ever. The information obtained by and through the British Fruit Growers’ Association at the Crystal Palace, and at the important National Conference subsequently held at Chiswick, has, by its wide distribution, done much to encourage fruit culture on safe lines, as have good provincial agencies. The papers read by practical men who do not dream golden dreams and narrate them to dazzle the multitude and lead the ignorant and confiding astray, will, it is hoped, in some degree counteract the wild rhapsodies that occasionally find their way into newspapers, and which, though not intended to mislead, are calculated to do so. Only men who have won reputations by their work—men of high character and of wide experience in horticulture, can be regarded as safe guides in this matter. It is most important that seekers for information examine closely into the credentials of those who constitute themselves, as scores do in various parts of the country, guides for the inexperienced. It is easy to err in planting fruit trees, and years may elapse before the initial mistakes are apparent. It is also easy to lead persons to expect much more than can be accomplished. The plain record of facts included in Mr. William Paul’s valuable Conference paper (see page 359), is worth infinitely more than all the ear-tickling orations of optimistic doctrinaires. Information on fruit culture for profit to be entirely trustworthy must be founded on accomplished facts, not on fanciful theories. The building up of fortunes from figures is easily done, and as in the past so in the future, the expected El Dorado may only be found on paper. Fruit culture conducted on sound lines is sufficiently profitable to justify a great extension, but it is well not to commence with extravagant anticipations that cannot be fulfilled.

As fruit-tree planting to a greater extent than formerly is a feature of the autumn, so also is the planting of Roses. The favourable weather, we are informed, has induced an unusually brisk demand for plants that are generally very fine and in condition for early removal. If they can be inserted while the earth heat is sufficient for inciting root action before winter the gain is considerable; but the temperature of the soil is lower than usual for the season, and will quickly fall to a point at which roots remain dormant, therefore early action in planting is desirable.

But fruit trees and Roses have only a share of public interest now. The queen of autumn, the Chrysanthemum, will soon be enthroned and thousands will do her homage. At no previous time were growers of plants and blooms so enthusiastic and admirers of them so numerous. This is the outcome mainly of the formation of societies and the encouragement they have afforded in stimulating high cultivation. The National Chrysanthemum Society, by the enlightened policy it has adopted and the enterprise it has exhibited on sound business lines, has won for itself a high position and the confidence of the community of which it is the recognised head. While more than ordinary interest attaches to all the coming shows, the Sheffield Tournament is the great centre of

attraction in November. Northern and southern growers are expected to meet in friendly rivalry; and probably at no time could they have met under more equal conditions, for the summer appears to have been almost alike in cold, cloud, and wet over the entire Chrysanthemum-growing area, with a dry October following everywhere. The results of those conditions remain to be seen, and these will perhaps not show a higher standard of excellence than has been previously established. It is certain the early October frost will be found to have impaired the quality of thousands of blooms, for thousands of buds were exposed to it, and the chief honours may be expected to fall to the wide-awake growers who housed their plants sooner than usual, or during the last week of September.

HARDY PLANTS FOR SPRING FLOWERING.
